The Catholic university of Louvain is governed by a grand rector, nominated and revocable by the episcopal body. A vice rector is also nominated by the episcopal body on the advice of the grand rector. The rector nominates the secretary and other functionaries of the university. The faculties are philosophy and literature, the mathematical, physical, and natural sciences, law, medicine, and theology. The courses of the five faculties are given by ordinary and extraordinary professors and lecturers, nominated by the episcopal body on the presentation of the rector. The enrolment-fee for the first year is 10 francs, and 5 francs annually thereafter. The annual fee for courses in the faculties varies from 200 to 250 francs, except the theological courses, which are gratuitous. It has an extensive library, cabinets of mineralogy, zoology, &c., and a botanical garden. The numbers of the students at each of the universities in 1874 were—Ghent, 222; Liége, 518; Brussels, 580; and Louvain, 909.

A competition takes place annually among the scholars of superior instruction, and at these competitions two gold medals are given in each of the faculties. There are also twelve travelling scholarships given annually, tenable for two years, to such students as have taken their doctor's degree with the highest distinction and wish to travel, to enable them to visit foreign countries; and about sixty bursaries of 400 francs each are given annually to poor students to enable them to prosecute their studies. Besides these there are connected with the universities a number of private bursaries, the management and bestowal of which are in the hands of particular persons or corporations in terms of the acts of foundation.

Special schools

The special educational institutions of Belgium are of various kinds, and are generally in a very efficient state. They include (in addition to the engineering and mining schools already mentioned) normal schools, military schools, navigation schools, &c., and academies and schools of design, painting, sculpture, music, &c.

Normal schools.

There are two Government normal schools for primary teachers, one at Lierre and the other at Nivelles,—the former having twelve and the latter thirteen professors, with a rector each. The course extends over three years, and during the last year of attendance the pupils are exercised in teaching in the primary schools of the town. There are also seven episcopal normal schools, in which similar branches are taught, except that the principles of the Catholic religion are more particularly inculcated. The chief diocesan nominates the rectors and professors. The course lasts for four years. Besides these there are several private normal schools for males and females, one or more institutions for the training of female teachers by each province, and normal primary sections attached to the middle schools of Bruges, Ghent, Huy, Virton, and Couvin.

Bursaries of 200 francs each are annually given by Government to assist poor students attending the normal schools; and students of promise, who have taken diplomas at either of the Government primary normal schools, may be admitted to the normal school of middle instruction at Nivelles. The course here is for two years. There are also for the training of teachers for the superior middle institutions, the normal school of the humanities at Liége, and the normal school of the sciences at Ghent. Candidates for admission must be young men of superior talents, qualifying them to perform creditably the duties of professor, and they must pass certain examinations. The branches taught in both schools extend over three years. In the school at Liége there are fourteen bursaries of 500 francs each, given to the poorer students, the recipients becoming bound to act as professors in one of the middle schools for five years. There are five bursaries of 500 francs in connection with the school at Ghent.

Military schools.

There is a military school at Brussels for training officers for the army. The number of scholars in 1873 was 129. The courses are divided into two sections; the one, which extends over two years, is preparatory to the second, which also extends over two years, and is divided into special branches qualifying for the infantry, cavalry, or marines. A school has been established in Lierre for the purpose of educating the sons of the military for the army. The course extends over five years, and the pupils generally enter the army about the age of sixteen. They are placed in the army according to their proficiency, some as sub-officers and corporals, others as common soldiers. The pupils in 1873 were 252.

Each regiment has a regimental school for training young men in the army for subalterns, and a number of evening schools for affording the means of education to the soldiery. Attendance at one of these schools is obligatory on all subalterns and corporals whose education is not complete, according to their position.

There is at Messines a Royal Institution for the education of daughters of military men who have died or been disabled in the service of their country. They are admitted from seven to fourteen years of age, and remain till their eighteenth year. They are instructed in branches necessary to qualify them as governesses, teachers, domestic servants, &c., and situations are provided for them on leaving.

Navigation schools

Schools of navigation have been established at Antwerp and Ostend for furnishing properly educated masters for merchant vessels, where instruction is given gratuitously. Certificates of qualifications as master or mate are given by a jury of examiners. There has also recently been formed at Antwerp a superior institute of commerce to afford instruction, theoretical and practical, in the commercial sciences, the course extending over two years.

A Government agricultural institute was established at Gembloux in 1860 for affording theoretical and practical instruction in agriculture and kindred subjects. There are seven professors and three assistants, and a demonstrative gardener. The course lasts for three years. Students in 1873, 71. There is a similar institution at Ghent, which in 1873 had 31 students. A school of practical horticulture and arboriculture was established at Vilvorde in 1855, which in 1873 had 29 students; the course is for three years. A similar institution at Gendbrugg has been closed since 1871. There is also a veterinary college at Brussels with, in 1873, 84 students. The course is for four years.

Academies.

The academies and schools of design, painting, sculpture, &c., are divided into three classes:—1. The royal academies of the fine arts, in which painting, sculpture architecture,

and engraving are taught in the most efficient manner; 2. Academies of design established in the principal towns, and giving instructions in designing, architecture, and the principles of geometry and perspective drawing; 3. Schools of design established in all the larger towns for instructing young persons and artisans in the elements of designing and architecture. In 1873 there were 76 such academies and schools in the kingdom, having 9966 pupils.

Academies of fine arts. The Royal Academy of the Fine Arts at Antwerp is principally intended to afford gratuitous instruction in painting, sculpture, architecture, and engraving, and to propagate and encourage a taste for the fine arts. In 1873 there were 1665 scholars. A competition in one of the branches of the fine arts is annually held in Antwerp, the laureate at which receives a pension of 3500 francs annually for four years, to enable him to perfect himself in his art in Germany, France, and Italy. The second prize is a gold medal of 300 francs. The Royal Academy of the Fine Arts at Brussels is an institution similar to that at Antwerp. Instruction is gratuitous, and the vacancies are filled up by competition.

Musical conservatory. The Royal Musical Conservatory at Brussels is under the direction of the minister of the interior, aided by a commission of seven members nominated by the king, with the burgomaster of Brussels as honorary president. The instruction is gratuitous, and includes vocal and instrumental music, composition, and the Italian language. The number of scholars in 1873 was 529. There are six bursaries of 250 francs, and ten of 125 francs, in connection with this institution. There is a similar establishment at Liége, with (in 1873) 694 scholars. Music, both vocal and instrumental, is much cultivated in Belgium; and musical schools and societies are established in almost all the principal towns and throughout the country. In 1873 there were, besides those mentioned, 108 musical schools and societies, with 7440 members. A competition in musical composition takes place every two years at Brussels, the laureate receiving a pension of 3500 francs for four years, to enable him to study in France, Germany, and Italy. The second prize is a gold medal of the value of 300 francs.

Learned societies. Belgium possesses a great number of learned societies, as the Royal Medical Academy, the Royal Academy of Science, Literature, and Art, &c. The Royal Medical Academy has its seat at Brussels. It is divided into six sections, and has 36 titular and 18 assistant members, with 24 corresponding and an indefinite number of honorary members. Each of the sections has certain branches of medical science assigned to it. The academy answers any questions that may be proposed to it by the Government, upon matters connected with public hygiene, and makes researches in all subjects connected with or tending to advance medical science. Gold medals are given annually for the best essays on prescribed subjects. It receives an annual grant of 20,000 francs from the state.

Academy of science. The Royal Academy of Science, Literature, and Art also has its seat at Brussels. It is divided into three classes, for the sciences, literature, and the fine arts; the first two are each subdivided into two sections, and the last into branches, for painting, sculpture, engraving, architecture, and music. Each class is composed of 30 members, 50 foreign associates, and not more than ten native correspondents. Each class proposes annually certain subjects for essays, to which gold medals of the value of 600 francs are adjudged. The academy receives an annual grant of 40,000 francs from the state. Connected with this academy is a royal commission of history for the purpose of searching for and editing old chronicles and documents tending to throw light upon the early history of the country. There has also just (1875) been instituted by the king a prize of 25,000 francs (£1000) to be given annually for the best work published on a subject previously announced of interest to Belgium. Every fourth year the competition is to be open to foreigners.

There is a Government inspector-general of science, literature, and art, who has the general superintendence of that department, under the minister of the interior. Under him are two administrative boards, the one for literature and science, and the other for the fine arts.

Royal observatory. The Royal Observatory for astronomical and meteorological observations is under the management of a director and three assistants. In the observatory are instruments specially provided by Government for the use of young men desirous of making meteorological or astronomical observations.

Museums. The Royal Museum of Brussels, for the reception of objects in natural history belonging to the state, is under the direction of a council of five members appointed by the king. There is also a museum of industry, containing models and plans of machines used in arts, manufactures, and agriculture. Annexed to this museum is a school where instruction is given gratuitously in the construction of such machines. It possesses a chemical laboratory, library, &c. There is also a royal museum of war instruments at Brussels, and in 1870 a royal botanic garden was laid out for aiding in the study of botany and horticulture. The royal museum of painting and sculpture is under the direction of a commission, composed of a president and six members nominated by the king, and charged with the collection of works of ancient and modern masters for the museum. A triennial exhibition of works of living artists, Belgian and foreign, in painting, sculpture, engraving, architecture, and lithography, is held at Brussels. There are similar exhibitions held in Antwerp, Ghent, Liége, Bruges, &c. The geographical establishment at Brussels has a considerable collection of books and maps, a garden, a herbarium, collections of rocks, lava, fossils, &c.

Public libraries. Besides the libraries belonging to different societies, associations, &c., there are a number of public libraries in Belgium. The principal of these is the royal library of Brussels. It contained in 1871 about 301,500 volumes, 22,221 manuscripts, 53,556 engravings, and 19,517 medals and coins. This is the only library that receives copies of copyright works. The public library of Ghent is connected with the university. It has 80,000 volumes and 600 manuscripts, besides pamphlets, &c. The Liége public library has 68,000 volumes, about 26,000 pamphlets, and 430 manuscripts. The public library of the Louvain university is the most ancient in Belgium, and is particularly rich in works of ancient history, theology, and literature, including Hebrew, Greek, Latin, and Oriental. These libraries are open daily for consultation, and in almost all of them volumes are lent out at the discretion of the conservators.

Archives. The archives of Belgium contain a great number of interesting and valuable documents connected with the history of the country. These are carefully preserved, classified, and catalogued. The general archives of the kingdom at Brussels contain upwards of 100,000 documents, and the archives of Antwerp upwards of 70,000. Those at Bruges, Ghent, Liége, Mons, Namur, Tournay, Hasselt, and Arlon are ancient and important. The archives of the city of Bruges, at one time the grand commercial entrepôt of Europe, contain a number of valuable papers bearing upon the events of which this city was the theatre in the Middle Ages. Unfortunately, they do not go further back than 1280, the previous documents having been all destroyed by an extensive fire in that year.

The benevolent and charitable institutions of Belgium are numerous and open to all. The duty of supporting

Charitable institutions.

them falls in the first instance upon the commune, afterwards upon the province, and finally, in case of necessity, upon the state. They are divided into three classes:—(1.) Those affording assistance or an asylum to the poor in case of age, infirmity, disease, want of work, &c., including dispensaries, foundling and maternity hospitals, deaf-mute and blind institutions, &c.; (2.) Those more particularly designed for the prevention and suppression of vagabondage and beggary, as depôts of mendicity and reform schools; and (3.) Those specially intended to foster a spirit of independence and foresight among the working classes, as savings-banks, and assurance and mutual assistance societies.

Every town of importance and many of the rural communes have hospitals for the aged, infirm, and indigent. Asylums for incurables are also numerous, but much less so than the former. Farm hospitals have been established in the rural communes of the two Flanders, where the inmates contribute by work to their own maintenance. They form small agricultural colonies of old people and children, mutually assisting each other. The products of the farms generally suffice for their maintenance.

Foundling hospitals are established in Antwerp, Brussels, Louvain, Bruges, Ostend, &c. The children generally remain only for a short time in the hospitals. They are pensioned out to inhabitants of the rural communes till their twelfth year, at which period the wardship of the hospital terminates. Inspectors are appointed to visit the children quarterly, to report upon their physical condition, see that they are attending school, &c. There are maternity hospitals at Brussels, Louvain, Ghent, Liége, Bruges, Nieuport, and Tournay, in several of which courses of midwifery are given. Maternity societies for aiding females with money, medicine, &c., are formed in many of the towns. There are a number of lunatic asylums, which in 1873 had in all 6801 patients, of whom 5024 were paupers. A colony of lunatics has been formed in the commune of Gheel, province of Antwerp, where, under the direction of a permanent committee, they are pensioned out among the inhabitants, and generally employed in agricultural labours. There are also a number of institutions for the education of the deaf and dumb and the blind.

To prevent the misery, and frequently the crime, arising from the want of employment among the working classes, charity workshops have been established in Ghent, Liége, and other towns. These are accessible to all workmen without employment and in poor circumstances. The able-bodied are paid according to their work, and the aged and infirm according to their necessities. The workshops of apprenticeship and improvement are intended not only to supply work to the unemployed, but principally to initiate the people in the exercise of new or improved branches of industry, and to instruct the young men in some trade or profession by which they may be able to gain an honest livelihood. They have been found of great benefit to many of the poorer classes who would otherwise have been brought up as vagrants and beggars. The apprenticeship generally lasts from four to six months. Similar to these are the manufacturing schools, intended principally for girls, where they are employed in the manufacture of lace, &c. These are supported partly by the state and partly by the province and commune, but many of them are private. In 1872 there were of these institutions—29 communal, 144 private but subject to inspection, and 294 non-inspected. The total number of persons was 26,739, of whom 1067 were in communal establishments, 9649 private inspected, and 16,023 non-inspected; 25,565 were females and 1174 males.

There are three depôts of mendicity or workhouses in the kingdom, at Bruges, Hoogstraeten, and Reckheim. In 1873 they contained 1819 persons. A reform school was founded in Ruysselede in 1848 for male vagrants and mendicants under eighteen years of age. It contains about 500 members, employed in cultivating a large farm of 128 hectares. At a short distance is a similar institution for 400 girls and infants, between two and seven years of age. There is also a similar school for girls and infants at Beernem.

In each commune is a *bureau de bienfaisance*, for assisting the poor with money, food, clothing, &c., and, where there are no hospitals, providing them with medical attendance and medicines. It also contributes to the maintenance and education of poor children, foundlings, deaf-mutes, and lunatics. There are also *Monts de Piété*, or charitable institutions for lending money to the poor upon the security of pledges, in twenty of the larger towns. *Caisses de prévoyance*, both general and special, and mutual aid societies—to succour the members in sickness, pay their funeral expenses, and aid their families—are numerous.

Judicial system.

The judicial system of Belgium consists of courts and tribunals of various kinds, as the court of cassation, the courts of appeal, and of assize, tribunals of primary instance, of commerce, &c. The court of cassation or annulment sits at Brussels, and is divided into two chambers, the one for civil and the other for criminal matters. It is composed of a president-general, a president of the chamber, and fifteen councillors. It decides upon appeals against judgments pronounced in the other courts and tribunals in contravention of legal forms. There are three courts of appeal: one at Brussels, for the provinces of Antwerp, Brabant, and Hainault; another at Ghent, for the two Flanders; and a third at Liége, for Liége, Limbourg, Luxembourg, and Namur. In the capital of each province is a court of assize, composed of a councillor, deputed from one of the courts of appeal, who presides, and two judges chosen from among the presidents and judges of the primary tribunal, where the court is held. Crimes, graver misdemeanours, political offences, and abuses of the press are judged by the courts of assize. In each judiciary arrondissement is a tribunal of primary instance, judging in misdemeanours belonging to the correctional police, in civil matters, and in commercial affairs where there is no commercial tribunal. The number of judges varies from three to ten in each tribunal. Tribunals of commerce are established by law in several principal towns. They judge definitively in civil matters of not more than 2000 francs, but above that sum their decisions are subject to appeal, as in the tribunals of primary instance. In several of the manufacturing towns are councils of *prud' hommes*, composed of master tradesmen and workmen. They decide in all questions and disputes arising between masters and workmen. For all criminal and political cases, as well as offences of the press, trial by jury is established. The jury is composed of twelve persons chosen by lot from a leet of thirty. Justices of the peace and judges of the tribunals are chosen directly by the king. The councillors of each court of appeal, and the presidents and vice-presidents of the tribunals of primary instance in its district, are chosen by the king from two double lists of candidates, the one presented by the court of appeal, and the other by the provincial council. The councillors of the court of cassation are named by the king from two double lists, the one presented by the senate, and the other by the court of cassation. The judges are appointed for life, and cannot be suspended or deposed but by a judgment. They cannot hold any salaried office under the Government, or, at least, must perform the duties of it gratuitously. The duties of public minister at the court of cassation are exercised by a procurator-general, and two advocates-

general; and by a royal procurator with substitutes before each of the tribunals of primary instance and courts of assize and appeal.

Councils of war are held in the chief place of each province, with the exception of Limbourg, which is joined to Liége, and of Luxembourg, which is united with Namur. They decide in crimes and misdemeanours committed in their provinces by the military of a rank not higher than captain. The military court for the whole of Belgium has its seat at Brussels. It is composed of five members, one of whom is a councillor of the appeal court of Brussels, delegated annually to preside; the rest are general or superior officers chosen by lot every month. All officers of a grade superior to that of captain are amenable to this court. It also decides on appeals from the provincial or other military courts.

Police. Besides the ordinary police, there are commissaries of police, royal procurators, *juges d'instruction*, &c. The commissaries of police, and in the communes where these are wanting the burgomasters or delegated aldermen, are specially charged with searching out and proving all contraventions of the police laws. The royal procurators are charged with discovering and prosecuting for all offences coming within the jurisdiction of the courts of assize or the correctional tribunals of police. There is at least one *juge d'instruction*, or examining judge, in each arrondissement who is specially charged with the collection of evidence, and with bringing the culprit before the tribunal. There is a council chamber composed of at least three judges, including the *juge d'instruction*, for the preliminary examination of culprits.

Prisons. The prisons are of three kinds—(1), central prisons; (2), houses of surety; and (3), houses of arrest. The central prisons are—(1), the central penitentiary at Ghent for different classes of criminals; (2), the penitentiary at Louvain, on the solitary system, for prisoners condemned to more than one year's imprisonment, except those condemned to imprisonment for life; (3), the penitentiary and reformatory for young criminals at Namur; (4), the penitentiary and reformatory at St Hubert for young delinquents belonging to the rural population, acquitted but put at the disposal of Government; (5), the branch penitentiary and reformatory at Namur for young criminals and young delinquents, acquitted, belonging to the town populations. The number in the prisons in 1873 was 1568, in the reformatories 751. The houses of surety are established in the capital of each province, where there is a court of assize, and the houses of arrest are in the capital of each arrondissement, the seat of a court of primary instance, where there is not already a house of surety. In these houses are confined the prisoners whose term does not exceed six months if the prison is a common one, and three years if on the solitary system. The number of prisoners in these prisons in 1873 was 2437. In connection with many of these, schools, workshops, and circulating libraries have been established. The prisoners are employed in various kinds of work. Those condemned to compulsory labour receive no remuneration, but those condemned to solitary or correctional imprisonment receive a part of the produce of their labour, which in the case of the latter is frequently applied in mitigation of their punishment. Premiums are also given for good conduct, zeal, and progress in their labours.

Agriculture. Since 1830 the agricultural state of the country has been much improved. A superior council of agriculture is specially charged with the promotion and superintendence of the agricultural interests of the country; and in each of the provinces a commission of practical men is nominated to encourage the introduction of improvements in the different branches of agriculture and report annually upon the state of agriculture in their provinces. Every five years a grand agricultural exhibition of horses, cattle, agricultural implements, and produce is held in Brussels, at which a number of gold and silver medals, &c., are given as prizes. Local exhibitions are also held frequently in the various districts.

The agriculturists above twelve years of age, including female servants, form one-fourth of the entire population. Females are extensively engaged in agricultural work, being to the males as 61 to 100. In 1866 the number of horses was 283,163; of cattle, 1,242,445; sheep, 586,097; swine, 632,301. To improve the breeds of horses a Government stud of stallions is maintained at Tervueren.

The cultivated land of Belgium amounts to 2,663,753 hectares, or 6,582,123 acres, of which 1,339,795 hectares are in the hands of the proprietors, and 1,323,958 are let to tenants. In West Flanders four-fifths are in the hands of tenants; in Luxembourg nearly five-sixths are in the hands of the proprietors; and in most of the other provinces about one-half is let to tenants. The land is divided into numerous and mostly small patches (nearly 600,000). Of these 43 per cent. do not exceed 50 ares; there are 12 per cent. not exceeding one hectare, or $2\frac{1}{2}$ acres, 29 per cent. not exceeding 5 hectares, $7\frac{1}{2}$ per cent. not exceeding 10 hectares, and less than 8 per cent. of greater extent. The Belgians, particularly in Flanders, are averse to the introduction of improvements in their agricultural operations, and their implements are generally rude and clumsy. Their lands are, however, cultivated with great care and are very productive. Of the cereal crops rye is the most extensively cultivated, and forms an important article of food for the working classes. Wheat and oats are also extensively cultivated, the former particularly in the provinces of Hainault, Brabant, and West Flanders. Comparatively little barley is raised. Hops, chicory, tobacco, rape, and other oleaginous plants, hemp, flax, madder, beet, &c., are common. Of these the most extensively cultivated is flax, principally in the two Flanders. Tobacco was much more extensively grown a few years ago than at present; it is now almost entirely confined to the two Flanders and Hainault. The chicory plant is principally raised in Hainault. The cultivation of beet for the extraction of sugar is continually increasing, and numerous establishments have been formed for its preparation. The leguminous plants, pease, beans, and tares, are used principally as fodder for cattle; the most common are beans. The beet root is even more extensively cultivated as fodder than as an industrial plant, particularly in the provinces of West Flanders, Liege, Hainault, and Brabant. Potatoes are largely grown in all the provinces; and, next to potatoes, turnips are the most extensively cultivated of the alimentary roots. The fallow ground, formerly considerable, is now only of small extent, being principally sown in fodder crops. Clover is the principal fodder crop. The number of hectares occupied with the principal crops in 1866 were—wheat, 283,542; oats, 221,743; rye, 288,966; barley, 43,617; beans, 24,263; pease, tares, &c., 13,645; potatoes, 171,397; flax, 57,045; colza, 26,412; beet root for sugar, 18,074; turnips, carrots, &c., 28,806; hemp, hops, chicory, tobacco, &c., 13,775. Vegetable gardens occupied 37,329; meadow, 365,805; fallow, 53,891.

Minerals. Belgium is rich in various kinds of minerals, as coal, iron, calamine, &c., which form a valuable source of employment to many thousands of its inhabitants.

The coal may be divided into two great basins. The western basin is the most important, and has an estimated extent of 90,051 hectares (or about 222,400 acres),—75,725 in the province of Hainault, and 14,326 in Namur. The extent of the eastern bed is estimated at 44,062 hectares,—41,745 in the province of Liége, and 2317 in

Namur. All varieties, from anthracite to the richest gas-coal, are found. In 1873 there were 285 coal-mines in the country, employing 107,902 persons, and producing 15,778,401 tons of coal valued at 337,637,360 francs. The iron districts are the arrondissement of Charleroi, and the provinces of Namur, Liége, and Luxembourg. Besides the iron-mines in Charleroi, Hainault contains a copper-mine, commenced in 1849, and calamine and blende mines. Iron is also found in small quantities in the arrondissements of Mons and Tournay. In Namur the iron ore is rich and plentiful, and constitutes the principal mineral wealth of the province. Veins of lead and zinc are also wrought to a considerable extent. The iron-mines of Luxembourg are much inferior to those of Namur. The principal are those of Durbuy, Ruette, Grandcourt, Halanzy, and Musson. The ferruginous basins of Theux and La Reid are of the greatest importance, both as public works, and from the quantity of ore that they furnish. Lead and zinc are found here almost always in the same bed. Alumiferous schist is common in several parts of the province. In 1873 the different metallic mines yielded 13,952 tons of blende, 28,630 of calamine, 11,280 of lead, 36,651 of pyrites, and 503,563 of buddled iron ore. The number of workmen employed in these mines was 3758. Under the minister of the interior the mines are superintended by a corps of mining engineers; each of the six mining districts has an ordinary engineer, and each of the two divisions a chief engineer. A sub-engineer is appointed over a certain number of mines.

Marble is abundant in many parts of Belgium; and the black marbles, as those of Dinant and Gochene, may rival the finest productions of other countries. There are also numerous quarries of freestone, granite, limestone, slate, &c. The principal quarrying provinces are Namur and Hainault. In 1873 there were 2230 quarries in the country, employing 22,435 men, and yielding the value of 38,353,171 francs.

The number of works in 1873 for the preparation of iron was 331; steel, 3; lead, 7; copper, 6; zinc, 1; alum, 1; glass, 72; and 41,845 workmen were engaged. The value of the iron manufactures was upwards of 246,000,000 francs; glass, 46,000,000; zinc, 38,000,000; steel, 7,700,000; copper, 6,000,000; lead, 4,700,000, &c.

Manufactures.

Notwithstanding many vicissitudes, flax, the most ancient, still forms one of the most important branches of industry in the country. In 1866, 57,045 hectares of land were occupied in the cultivation of flax, and a considerable number in hemp. The declared value in flax and hemp yarn imported in 1872 was 10,427,000 francs; of flax yarn exported, 80,904,000; of hemp, 7,155,000; and of flax and hemp cloths, 37,170,000.

Cotton also forms an important branch of industry, which is at present in a more flourishing condition than at any former period. In 1872 the value imported of raw cotton was 57,241,000 francs; cotton yarn, 5,214,000; and cotton cloths, 12,754,000; the value exported of cotton yarn, 6,358,000; cotton cloths, 19,083,000.

The manufacture of woollens forms also an important branch of industry. The wool for this purpose is principally imported from Prussia, Saxony, &c., the native produce being small in quantity and chiefly used in hosiery. In 1872 the value of the wool imported was 160,079,000 francs; yarn, 6,902,000; manufactured stuffs, 23,814,000; exported wool, 10,291,000; yarn, 64,523,000; manufactured stuffs, 44,850,000.

In 1866 the numbers employed in the various flax, hemp, woollen, and cotton manufactures, were 114,547 males and 71,111 females. The chief of the other manufactures are silk, lace, ribbons, beer, spirits, vinegar, sugar, salt, bricks and tiles, porcelain, earthenware, glass, crystal, paper, leather, ropes, &c. In 1872 the excise duties on beer and vinegar amounted to 15,547,605 francs; spirits, 16,946,225; foreign wines, 4,765,800; and sugar, 7,516,388.

Commerce.

In 1850, 2165 sailing and steam vessels, of 314,797 tons, entered Belgium; in 1860, 3780 vessels of 667,287 tons; in 1870, 5658 vessels, of 1,575,293 tons; and in 1872, 6134 vessels, of 1,878,106 tons. Of the last 3082 were steam vessels, of 1,158,484 tons. In 1850 the number of vessels that left Belgium was 2214, tonnage 235,745; in 1860, 3959, tonnage 694,225; in 1870, 5406, tonnage 1,534,513; and in 1872, 6241, tonnage 1,907,530. Of the last 3081 vessels, with 1,169,254 tons, were steamers. The numbers and tonnage of vessels entering from and leaving for different countries in 1872 were as follows:—

Inwards.			Outwards.		
	Vessels	Tonnage.		Vessels	Tonnage.
England	3176	843,779	England	4178	1,214,979
Russia	444	178,371	Sweden and Norway	544	124,354
Sweden and Norway	638	155,597	United States	121	94,790
United States	173	116,622	Germany	236	79,780
Argentine Rep.	169	95,575	France	209	65,913
Germany	312	87,785	Russia	148	56,646
France	218	62,182	Argentine Rep.	44	38,309
Chili and Peru	49	50,514			

Expressed in millions of francs the value of the imports in 1850 was 236; of the exports, 263; of goods in transit, 206: in 1860—imports, 516; exports, 469; in transit, 408: in 1870—imports, 520; exports, 690; in transit, 857: and in 1872—imports, 1277; exports, 1051; in transit, 1049. Of the imports in 1872, 315 were from France, 230 from England, 164 from Holland, 158 from the German Zollverein, 80 from the United States, 77 from the Argentine Republic, 62 from Russia, 35 from Uruguay, 24 from Brazil, and 23 from Sweden and Norway. Of the exports 320 were to France, 237 to England, 223 to the German Zollverein, 120 to Holland, 18 to Switzerland, 17 to the Hanseatic towns, 14 to the United States, 12 to Italy, and 11 to Russia. Of the goods in transit 434 were from the German Zollverein, 321 from France, 96 from England, and 92 from Holland; 341 were to the German Zollverein, 245 to England, 237 to France, and 121 to Holland. The values of the principal articles of merchandise imported for home consumption expressed in millions of francs were—wool, 160; grain of all kinds, 126; raw hides, 71; iron ore and cast and wrought iron, 61; cotton, 57; resins, 48; minerals and metals, 47; coffee, 42; wood for building, 41; grease and tallow, 37; silks, 30; horned cattle, 29; oleaginous seeds, 29; woollen stuffs, 23; fermented liquors, 21; oils, 17; machinery, 10. The values of the principal exports were—coal, 85; flax, 80; wrought iron, 69; woollen yarn, 64; raw hides, 53; woollen stuffs, 44; raw sugar, 41; machinery, 39; flax and hemp stuffs, 37; grain of all kinds, 37; flax and hemp yarn, 31; grease and tallow, 25; paper, 21; resins, 21; unwrought zinc, 21; coke, 20; cotton stuffs, 18; glass and crystal wares, 17; wool, 16; candles, 15; butter, 14; arms, 13. The values of the principal goods in transit were—flax and hemp stuffs, 204; wool, 147; woollen stuffs, 102; haberdashery and hardware, 39; silks, 38; cast and wrought iron, 35; cotton, 33; grain of all kinds, 30; coffee, 23; woollen yarn, 20; flax and hemp yarn, 19; cattle, sheep, swine, 18; cotton stuffs, 17; fermented liquors, 16; glass and crystal wares, 16; machines, 13. In 1872 the exports from Belgium to the United Kingdom were £13,211,044, and the imports from the United Kingdom to Belgium £6,499,062.

Chamber of commerce.

There are twenty-three chambers of commerce and manufacture established in the principal towns, the members of which are nominated by the king from a triple list of

candidates presented to him by the chambers. The members of each vary in number from nine to twenty-one, one-third going out annually. They present to the Government or legislative chambers their views as to the best means of increasing the commercial and industrial prosperity of the country, report annually upon the state of their districts, and give useful information or direction to the provincial or civic authorities under their administration. There is a superior council of industry and commerce, composed of two delegates chosen annually by each of the chambers of commerce of Antwerp, Brussels, Ghent, Liége, Mons, and Charleroi, one elected by each of the other chambers of commerce, and a certain number of members chosen by the king, not exceeding a third of the others. The president and two vice-presidents are nominated by the king for each session. The council considers matters affecting commerce and industry, and such questions connected therewith as may be submitted to it by the Government.

Public companies.

Belgium possesses a great number of commercial and financial associations, joint-stock companies for carrying on public works or other enterprises, assurance companies, private banking companies, railway companies, &c. It has eight commercial exchanges, under the direction of Government, namely, in Antwerp, Brussels, Ghent, Bruges, Ostend, Mons, Termonde, and Louvain. In 1822 the General Society for the Encouragement of National Industry was formed at Brussels, under a royal charter for 27 years, which has since been extended to 1875 and 1905. It has a social capital of 15,500,000 florins, divided into shares of 500 florins each, bearing interest at 5 per cent. The administrative body consists of a governor, six directors, a secretary, and a treasurer. It discounts bills, receives money at interest, grants loans and advances on titles and other deposits, &c. The National Bank, instituted by charter granted in 1850 and renewed 1872, has its seat at Brussels, and has branches in all the provincial capitals and several other towns. Its capital is 50,000,000 francs, in shares of 1000 francs each. It pays a dividend of 5 per cent. upon the shares, and one-third at least of the profits exceeding 6 per cent. goes to form a sinking fund. The administration consists of a governor nominated by the king, six directors, and a council of censors. The banking operations are superintended by a Government commissary; and a report upon its state is presented to the Government every month. The state funds are deposited in this bank. The Bank of Belgium, chartered in 1835, has a capital of 50,000,000 francs. Its seat is at Brussels. The Bank of Flanders, established in Ghent, has a capital of 10,000,000 francs.

Roads.

After England, there is no country in Europe where, in proportion to its extent, the roads are more numerous or better kept than in Belgium. They are of three kinds,—those maintained by the state, and those by the provinces and communes. The total length of the two latter cannot be given with accuracy; that of the first is 1187 leagues.

Railways.

A bill was passed in 1834 authorizing the establishment of a system of railroads, of which Malines was to form the centre, and the line from Brussels to Malines, opened May 5, 1835, was the first railway in operation on the Continent. The Government railways are wrought on account of the Government, and are under special administration. The total length of the various lines of railway in operation in 1873 was 616 leagues (of 5000 metres), of which 125 leagues belonged to the state, and 543 were conceded to others; of the former 117 leagues were double lines. The amount expended by Government in the construction of railways to the end of 1873 was 361,287,299 francs, or £14,451,491.

Postage.

In 1849 a system of postage was introduced into Belgium similar to that in this country. In 1873 the total number of letters that passed through the post-office was 55,654,859; newspapers, 52,771,524; and packets of printed matter, 25,697,330. In 1860 the numbers were—letters, 23,960,846; newspapers, 26,358,020; and book parcels, 6,668,452.

Telegraphs.

The first electric telegraph, which was that between Brussels and Antwerp, was introduced into the country in 1846 by an English company. A law passed in 1850 authorized the Government to purchase this, as also to establish telegraphs on all the lines of railway. The telegrams sent out in 1873 were 1,739,817 to different parts of the country, and 676,393 to other countries, besides 153,330 in transit.

For an account of the Belgian army and civic guard, see ARMY, vol. ii. p. 615.

Revenue and Expenditure.

The following table shows the annual income and expenditure for various years:—

	Income.	Expenditure.
1844	198,810,508 fr.	195,185,657 fr.
1850	132,877,187	118,730,904
1860	155,621,571	159,025,377
1865	169,055,072	188,793,737
1870	190,537,002	216,907,800
1871	207,705,993	238,191,223
1872	213,352,689	251,974,513

The details of the revenue and expenditure of the last three of these years, arranged under their several heads, are as follows:—

	Revenue.				Expenditure.		
	1870.	1871.	1872.		1870.	1871.	1872.
	Francs.	Francs.	Francs.		Francs.	Francs.	Francs.
Land tax	19,176,009	19,272,846	20,258,082	Public debt	42,680,891	47,628,453	48,765,178
Personal tax	12,174,694	12,404,060	13,230,057	Pensions	4,367,879	4,366,898	4,288,619
Trade licences	4,374,797	5,103,814	5,509,728	Justice	14,620,711	14,515,530	14,473,638
Rent of mines	440,020	528,251	572,377	Foreign affairs	3,819,005	4,277,056	4,374,445
Customs duties	22,057,152	20,339,578	18,943,388	Interior	13,179,716	14,056,431	14,714,366
Excise duties	29,495,085	25,219,641	27,024,218	Public works	39,804,463	51,032,306	59,341,272
Stamp duties	39,633,635	44,806,269	49,277,477	War	59,116,612	44,005,577	39,590,955
Domains, Forests, &c.	3,444,497	2,413,004	2,555,137	Finance	13,308,096	13,545,257	13,936,198
Post-office	4,114,555	5,123,506	4,723,594	Deficiencies & Repayments	946,553	839,598	1,403,490
Railways, &c.	41,825,031	57,172,844	58,428,526	Special services	25,063,874	43,924,117	51,086,352
Miscellaneous	11,839,645	13,486,213	10,970,612				
Reimbursements	1,961,882	1,835,067	1,859,493				
Total	190,537,002	207,705,993	213,352,689	Total	216,907,800	238,191,223	251,974,513

Public debt.

The public debt of Belgium at the end of 1873 amounted to 966,920,513 francs or £38,676,820. Except the share of the old debt of the Netherlands which fell to it most of the national debt has been incurred in the construction of railways and other works of public utility.

History.

In the time of the Romans this portion of the Netherlands was included in Gaul, and formed part of that division of it which was known as *Gallia Belgica*. It was inhabited mostly by Celtic tribes, but there were also not a few of German race. The latter were subsequently largely

increased by irruptions from the north, so that in the 5th and 6th centuries, under the rule of the Franks, they formed the principal element of the population. For several centuries the history of the Franks is the history of the Netherlands. Afterwards the country was divided into a number of independent duchies, counties, and free cities. Among these may be mentioned the duchies of Brabant, Limbourg, and Luxembourg, the counties of Flanders, Hainault, and Namur, the bishopric of Liége, the lordship of Malines, &c. Of these the county of Flanders rose to be superior to all the others, and became distinguished for its industry and commercial activity. In 1385 the male line of the counts of Flanders became extinct, and their possessions passed into the hands of the dukes of Burgundy, who soon after, in various ways, came into possession of the whole of the Netherlands. In order to strengthen their power they sought to repress the spirit of liberty, and to do away with the free institutions that had sprung up in the country; but notwithstanding this the people continued to increase in wealth and prosperity, and industry and commerce flourished more and more among them. In 1477 Mary of Burgundy, only daughter and heiress of Charles the Bold, married the Archduke Maximilian, son of the Emperor Frederick IV., and thus the Netherlands came into the possession of the House of Austria. Maximilian succeeded to the imperial throne in 1493, and the following year he resigned the government of the Netherlands to his son Philip, then a youth of seventeen years of age. The latter, in 1496, married Joanna, daughter of Ferdinand and Isabella of Castile, and died in 1506, leaving to succeed him a son who afterwards became Charles V. During the reign of this monarch the Protestant religion began to spread in the country, though its adherents were subjected to much persecution. His son and successor, Philip II. of Spain, by his cruel persecutions and his attempt to establish the Inquisition in the country, drove the people into open rebellion. The duke of Alva, who was sent at the head of a Spanish army to reduce them to subjection, perpetrated upon them the most horrid cruelties, devastating the country in every direction, and erecting scaffolds in every city. At length the northern portion of the Netherlands succeeded in establishing its independence, and became the republic of the Seven United Provinces, while the southern portion, or Belgium, continued under the rule of Spain. In 1598 Philip ceded Belgium to his daughter Isabella and her husband the Archduke Albert, under whom it formed a distinct and independent kingdom. Attempts were then made to restore the prosperity of the country and improve its internal condition; but, unfortunately, Albert died without leaving issue in 1621, and the country again fell into the hands of Spain.

For many years Belgium continued to share in the declining fortunes of Spain; and in the wars that broke out between that power and France and Holland, it was exposed to the first attack, and peace was usually purchased at the expense of some part of its territory. By the treaty of the Pyrenees (1659) the county of Artois, Thionville, and other districts were ceded to France. Subsequent French conquests, confirmed by the peace of Aix-la-Chapelle (1668), took away Lille, Charleroi, Oudenarde, Courtray, and other places. These were, indeed, partly restored to Belgium by the peace of Nimeguen (1679); but, on the other hand, it lost Valenciennes, Nieuport, Cambray, St Omer, Ypres, and Charlemont, which were only in part recovered by the peace of Ryswick (1697). After the conclusion of this last treaty the Spanish Government attempted to restore prosperity to Belgium by the introduction of new customs laws, and by other means, particularly by the construction of canals to counteract the injury done to its commerce by the closing of the navigation of the Scheldt by the Dutch. But these attempts were of little avail in consequence of the breaking out of the War of the Spanish Succession, which was only brought to an end by the peace of Utrecht in 1713. By this treaty Belgium was assigned to Austria, and took the name of the Austrian Netherlands. Yet such was the enfeebled state of the country that Holland retained the right, which had been conceded to her during the late war, of garrisoning the principal fortresses on the French frontier, and her right to close the navigation of the Scheldt was also recognised. In 1722 a commercial company was formed at Ostend by Charles VI., but this was sacrificed in 1731 to the jealousy of the Dutch. During the Austrian War of Succession almost the whole country fell into the hands of the French, but was restored to Austria by the peace of Aix-la-Chapelle (1748). Belgium was undisturbed by the Seven Years' War (1756–63), and during the long peace which followed enjoyed considerable prosperity under the mild rule of Maria Theresa, whose representative here, Prince Charles of Lorraine, conducted affairs with great judgment and moderation. The empress did much for the advancement of education, founding, among other institutions, the Belgian Academy of Sciences, and opposed the undue power of the clergy. Her son and successor, Joseph II., got into difficulties with Holland, and compelled that power to withdraw her garrisons from the frontier towns, but was unsuccessful in his attempts to free the navigation of the Scheldt. It was, however, in his attempts to reform internal abuses that he failed most signally here as in other parts of his dominions. He excited the religious feelings of the people against him, by attempting to curb the power of the priests, and he offended the states by seeking to overturn the civil government. Numbers of the malcontents left the country, and organized themselves as a military force in Holland. As the discontent became more general the insurgents returned, took several forts, defeated the Austrians at Turnhout, and overran the country. On 11th December 1789, the people of Brussels rose against the Austrian garrison, and compelled it to capitulate, and on the 27th the states of Brabant declared their independence. The other provinces followed, and, on 11th January 1790, the whole formed themselves into an independent state under the name of United Belgium, with a congress to manage its affairs. After the death of Joseph II. his successor, Leopold II., issued a proclamation on 3rd March 1790, wherein he promised the restoration of the former constitution if the people would return to their allegiance. This, however, they refused to do, and they also rejected the proposal of a congress to meet at the Hague for the settlement of their differences. In the end of November, therefore, a strong Austrian army was sent into Belgium, and the country was subdued without any great opposition. The constitution as it existed at the end of the reign of Maria Theresa was restored, an amnesty was proclaimed for past offences, and the opposition of the states was put down. The short period of peace which followed was terminated by the breaking out of the war with revolutionary France. The battle of Jemappes (7th Nov. 1792) made the French masters of the country to the south of Liége; and the battle of Fleurus (26th June 1794) put an end to the Austrian rule in Belgium. The treaty of Campo Formio (1797) and the subsequent treaty of Luneville (1801) confirmed the conquerors in the possession of the country, and Belgium became an integral part of France, being governed on the same footing, receiving the *Code Napoleon*, and sharing in the fortunes of the Republic and of the Empire. (See FRANCE.) After the fall of Napoleon and the conclusion of the first peace of Paris (30th May 1814), Belgium was for some months ruled by an Austrian governor-general, after which it was united with Holland under

Prince William Frederick of Nassau, who took the title of king of the Netherlands (23d March 1815). The Congress of Vienna (31st May 1815) determined the relations and fixed the boundaries of the new kingdom; and the new constitution was promulgated on the 24th of August following, the king taking the oath at Brussels, Sept. 27.

The union, however, was not a particularly fortunate or happy one. It was brought about by the allied powers with little regard to the wishes or inclinations of the people, their main object being to form here a strong kingdom to serve as a check upon the ambitious designs of France. The character, habits, language, and religion of the Belgians were all against such an alliance. Through their connection and intercourse with France they had acquired much of the spirit, habits, and ideas of the people of that country; while the slow, staid, conservative habits and ideas of the Dutch were repugnant to them. The Belgians were chiefly engaged in agriculture and the manufactures, while the Dutch were mainly given to commerce and the fisheries. The French was the common language of Belgium, at least in the higher circles and in all public proceedings. But the principal difficulty arose from the difference in religion. The Roman Catholic clergy of Belgium were from the first opposed to a union with a Protestant country like Holland, and the great mass of the people were very ignorant, and much under the influence of the priests. Nevertheless, had a mild and conciliatory policy been adopted by the Dutch it would have done much to remove or lessen these difficulties. This, however, was not done. Belgium was regarded too much in the light of a conquered country, at whose expense they might lawfully enrich themselves. Though the population of Belgium was 3,400,000 and that of Holland only 2,000,000, the latter had as many representatives in the States-general as the former. This frequently rendered decision on important legislative questions a matter of extreme doubt and difficulty. In matters that affected, or were believed to affect, the two countries in different or opposite ways, the decision often depended on the accidental absence of a member on the one side or the other. The use of the French language was also attempted to be abolished in all Government and judicial proceedings. The great majority of the public offices were filled by Dutchmen, and the government was conducted principally in the interests of Holland. In 1830, of the seven Government ministers only one was a Belgian; in the ministry of the interior, of 117 officials only 11 were Belgians; in the ministry of war, of 102 officials only 3 were Belgians; and among 1967 officers of the army, only 288 were Belgians. The partisans of Holland attempt to explain away these facts, but with only very partial success; both sides, however, acquit the king of any intentional unfairness, and consider that he was led to act as he did by force of circumstances. The Belgians admit that he always manifested a sincere regard for their welfare, but accuse him of giving too ready an acquiescence to what they tauntingly called the schemes of their *Dutch cousins.*

Notwithstanding these drawbacks Belgium enjoyed during her union with Holland a degree of prosperity that was quite remarkable. The mineral wealth of the country was largely developed, the iron manufactures of Liége rapidly advanced in prosperity, the woollen manufactures of Verviers received a similar impulse, and many large establishments were formed at Ghent and other places where cotton goods were fabricated which rivalled those of England and far surpassed those of France. The extensive colonial and foreign trade of the Dutch furnished them with new markets for their produce; while the opening of the navigation of the Scheldt raised Antwerp to a place of the first commercial importance. The Government also did much in the way of improving the internal communications of the country, in repairing the roads and canals, and forming new ones, deepening and widening rivers, and the like. Nor was the social and intellectual improvement of the people by any means neglected. A new university was formed at Liége, normal schools for the instruction of teachers were instituted, and numerous elementary schools and schools for higher instruction were established over the country. That the Government should take upon itself the direction and regulation of the education of the people was particularly hateful to the priests, still more so were the attempts subsequently made to improve the education of the priests themselves. The king had determined that no priest should be inducted who had not passed two years in the study of the *literæ humaniores* before his ordination; and he appropriated a college at Louvain for that purpose, some of the professors in which were not priests, but laymen and Protestants. This gave great offence to the prelates and clergy, and some of the former, who had indulged in very intemperate language, were prosecuted. These proceedings were at the time applauded and encouraged by the active party of the Liberals, but afterwards these saw it their interest to join with the most bigoted of the Roman Catholics against the Government. With the view of terminating these differences the king in 1827 entered into a *concordat* with the Pope, settling the right of nomination to the bishoprics, and providing that the education of the priests should be under the control of the prelates, but that in the seminaries professors should be appointed to teach the sciences as well as what related to ecclesiastical matters. This, however, was far from satisfying the more violent of the clergy; and the two most opposite parties, the Catholic Ultramontanes and the French Liberals, united their efforts to effect the overthrow of the Government. The Liberals affected a zeal for the Catholic faith, and urged the clergy to make extravagant demands upon the Government, which they knew if granted would be hurtful to it, and if refused would increase the agitation then going on. Brussels was at this time, too, a city of refuge for the intriguing and discontented of almost every country of Europe, and the press teemed with libels not only against the Belgian Government, but also against almost every other, so that the people were constantly kept in a high state of political excitement. At length the Government took proceedings against some of the more notorious of the inflammatory writers, and several of them were banished from the kingdom.

Matters were in this state when the news of the success of the Paris revolution of 1830 reached Belgium. Numbers of the propagandists came to Brussels, where they paraded the streets and talked loudly in the public places of the glories of the Revolution and of the future destinies of France. The first outbreak occurred on the 25th of August, just a month after the commencement of that of Paris. A play, called *La Muette*, which abounds in passages well calculated to inflame the populace in their then excited state, was performed in the theatre, and when the curtain fell the audience rushed out into the street shouting, "Imitons les Parisiens." They were speedily joined by others, and the mob at once proceeded to deeds of violence, destroying or damaging a number of public buildings, manufactories, and private houses. The guards and posts in the centre of the city were overcome or quietly surrendered; the troops were drawn out, but they were too few in number to contend with the insurgents, and they either retreated to their barracks or were withdrawn to the upper part of the city, where they piled their arms in front of the king's palace, and renounced all attempts at suppressing the tumult. A number of the more influential and the middle-class citizens now enrolled themselves into a burgher guard for the protection of life and property, and to interpose in

a manner between the contending parties. The intelligence of these events in the capital soon spread throughout the provinces; and in most of the large towns similar scenes were enacted, commencing with plunderings and outrages by the mobs, followed by the institution of burgher guards for the maintenance of peace. The burgher guard of Brussels was most anxious to terminate the dispute without recourse being had to extreme measures. They demanded the dismissal of the minister, Van Maanen, who was obnoxious to the people, and a separate administration for Belgium without an entire separation of the two countries. The Government neither agreed to make these concessions nor did it resolve upon actual force, but adopted a sort of middle course which, by allowing things to go on, ended in converting a popular riot into a complete revolution. The heir-apparent, the prince of Orange, was sent on a peaceful mission to Brussels, but furnished with such limited powers as, in the circumstances, were utterly inadequate. On his arrival a conference was held, which extended over several days; and at the final meeting on 3d Sept., when a number of the members of the States-general were present, the prince had become so convinced that nothing but a separate administration of the two countries would restore tranquillity, that he promised to use his influence with his father to bring about that object—the persons present on their part assuring him that they would heartily unite in maintaining the dynasty of the House of Orange. The king summoned an extraordinary States-general, which met at the Hague, 13th Sept., and was opened by a speech from the throne, which was firm and temperate, but by no means definite. The proceedings of the body were dilatory, and the conduct of the Dutch deputies exasperated the people of Belgium beyond measure. The moderate party in the country gradually lost their influence, and those who were in favour of violent measures prevailed, while the warlike demonstrations made by the troops kindled a feeling of animosity and stimulated preparations for defence. Although the states were still sitting at the Hague, the king's army was gradually approaching Brussels. It consisted of 14,000 well-appointed troops under the command of Prince Frederick; but its movements were too tardy if force was to be employed, and it was entirely out of place if conciliatory measures were to prevail. On 20th September the council resolved to take possession of Brussels, believing that the inhabitants were eager to receive the troops, and that their presence there would tend to restore peace; and orders were sent to Prince Frederick to that effect. On the 23d the troops advanced towards the city, and, with little opposition, occupied the upper or court portion of it, which is situated on a hill, by which the rest of the town is commanded. The fighting continued for three days without any definite result, when the prince ordered a retreat. The news of this soon reached Ghent, Bruges, Ostend, and other towns, which at once declared in favour of separation. A Provisional Government was formed at Brussels, which declared Belgium to be an independent state, and summoned a national congress for the regulation of its affairs. The council of the king now consented to separate administrations for the two kingdoms, but it was too late to restore peace. Antwerp was the only important town which remained in the hands of the Dutch, and the army on leaving Brussels had fallen back on this town. In the end of October an insurgent army had arrived before the gates, which were opened by the populace to receive them, and the troops, under General Chassé, retired within the citadel. A truce was concluded between the parties, but the Belgian officers were unable to restrain the fury of the populace who, with such weapons as they had, attacked the citadel. The general ordered a cannonade and bombardment of the town, which continued for two days, destroying a number of houses and large quantities of merchandise. A suspension of hostilities then took place, but the misrepresentations and exaggerations of the proceedings which spread did much to inflame the minds of the Belgians still farther against the Dutch.

A convention of representatives of the five great powers met in London, in the beginning of November, at the request of the king of the Netherlands, but its attention was mainly directed to bringing about peace, and through it both sides were brought to consent to a cessation of hostilities. On the 10th November the national congress assembled at Brussels, consisting of 200 deputies chosen from the different provinces. Three important questions were decided by that assembly:—(1.) The independence of the country,—carried unanimously; (2), a constitutional hereditary monarchy,—by a majority of 174 against 13 in favour of a republic; and (3), the perpetual exclusion of the Orange Nassau family,—by a majority of 161 against 28 in favour of delay. On 20th December the conference of London proclaimed the dissolution of the kingdom of the Netherlands, at the same time that it claimed for itself the right of interfering even against the will of both countries to regulate the conditions of partition. On the 28th of January 1831 the congress proceeded to the election of a king, and out of a number of candidates the choice fell on the duke of Nemours, second son of Louis Philippe, but he declined the office. The congress then resolved on the election of a regent as a temporary measure, and they selected Baron Surlet de Chokier, who was installed on the 25th of February. This, however, did little to restore tranquillity to the country, and the partisans of the prince of Orange were still actively intriguing in his favour. At length, in the month of April, a proposition was privately made to Prince Leopold of Saxe-Coburg, widower of the Princess Charlotte of England, with the view of ascertaining whether, if chosen, he would accept the crown. It is remarkable that though his name was mentioned he was not among the number of candidates brought forward on the previous occasion. He answered in the affirmative, but strictly abstained from giving any authority to exertion being made in his favour. After many stormy discussions the election at length took place on the 4th of June, when 152 votes out of 196, four only being absent, determined that Prince Leopold should be proclaimed king of the Belgians, under the express condition that he "would accept the constitution and swear to maintain the national independence and territorial integrity." Leopold at once accepted, and made his public entry into Brussels on the 21st, when he was received with great cordiality. He subsequently visited other parts of the kingdom, and was everywhere received with demonstrations of loyalty and respect. While this was going on news suddenly arrived that the Dutch were preparing to invade the country with a large army. This had been brought together so secretly that the Belgians were unaware of its existence till it was about to cross the frontier. It comprised 45,000 infantry and 6000 cavalry, with 72 pieces of artillery, while Leopold could scarcely bring forward 25,000 men to oppose it. On the 2d of August the whole of the Dutch army had crossed the frontier. Leopold collected his forces, such as they were, near Louvain in order to cover his capital. The Dutch army advanced to the attack (9th August), and though the king displayed great bravery and determination, he was unable to impart his spirit to his undisciplined troops, who were speedily routed, the king himself and his staff making a narrow escape from being taken prisoners. He, however, made good his retreat to the capital; and a French army, which was ready to enter the country, then advanced, and the Prince of Orange saw the necessity of

retreating. A convention was concluded between him and the French general, in consequence of which he returned to Holland and the French army repassed the frontier.

Leopold now proceeded with vigour to strengthen his position, and to restore order and confidence. French officers were selected for the training and disciplining of the army, the civil list was arranged with economy and order, and the other branches of the public service were reformed or rearranged. He kept on the best terms with the Roman Catholic clergy and the Roman Catholic nobility; and his subsequent marriage with a daughter of the French king (9th August 1832), and a contract that the children of the marriage should be educated in the Roman Catholic faith, did much to inspire confidence in his good intentions. While these things were going on the conference in London was engaged in determining the terms of peace, and a project of a treaty for the separation of the two states was drawn up and declared to be "final and irrevocable." The first basis of separation had determined that the grand-duchy of Luxembourg, which belonged to the king of Holland as grand-duke, should continue to belong to Holland. By the subsequent treaty of the eighteen articles, Belgium received the right to treat for the purchase or redemption of Luxembourg from Holland on fair terms. These articles were adopted by the Belgian congress in July 1831, but the king of Holland rejected them, and followed up his rejection, as we have seen, by the invasion of Belgium. The terms of the treaty which followed this invasion were much more favourable to Holland than those of the previous one; for the feeble resistance that Belgium had been able to make had affected very unfavourably the directing powers, who considered that, in the interests of the peace of Europe, their first duty was to strengthen the defensive power of Holland. The new proposals, therefore, caused great excitement in Belgium, and met with much opposition; but, eventually, they were adopted by a majority of 59 to 38 in the Chamber of Representatives, and 35 to 8 in the Senate.

The treaty was signed on 15th November, and its conditions were embraced in twenty-four articles. By these articles the grand-duchy of Luxembourg was to be divided, but the fortress of Luxembourg was to remain in the hands of the king of Holland as grand-duke, who was also to receive a portion of Limbourg for the part of Luxembourg ceded to Belgium. The district of Maestricht was also partitioned, the fortress of that name remaining with Holland; the Scheldt was to be open to the commerce of both countries; and the national debt was apportioned—to Belgium sixteen thirty-firsts, and the rest to Holland. It was also declared that Belgium "shall form an independent and perfectly neutral state."[1] This agreement was ratified by the Belgian and French sovereigns on the 20th and 24th November, by the British, 6th December; but the Austrian and Prussian sovereigns did not accede to it till 18th April 1832, and the Russian not till 4th May. The Dutch still continued to protest against it, and maintained their possession of Antwerp. After fruitless efforts on the part of the great powers to obtain their acquiescence, France and England resolved to have recourse to force. On the 5th November, therefore, their combined fleets sailed for the coast of Holland, and on the 18th, a French army, under the command of Marshal Gérard, crossed the Belgian frontier to besiege Antwerp. The garrison consisted of only about 5000 men, while the besieging force numbered 60,000. Operations commenced 30th November, and the siege in a military point of view is a memorable one. The garrison surrendered to the French on 23d December, on the 31st the fortress was handed over to the Belgians, and some days afterwards the French troops recrossed the frontier. Long and complicated diplomatic negotiations followed, but matters were at length adjusted, and on the 21st of May 1833 a convention was agreed to and signed by all the parties. The House of Orange still numbered many partisans in Belgium, whose proceedings embarrassed the Government; and in Brussels, and some of the other towns, the people rose up against them, pillaging the houses of some of the leaders, and were appeased with difficulty. The king now gave his attention to the improvement of the manufactures and commerce of Belgium; and on 1st May 1834 he sanctioned the law which was to create the first railroad on the continent of Europe.

In 1835 the alien bill gave rise to considerable discussion, but it was at length carried. Its object was to give Government the power to send out of the kingdom, or to compel to reside in a particular place, any foreigner whose conduct was calculated to endanger the public peace. In 1836 an Act to regulate the municipal form of government in the towns and communes was passed. The election of the members of the municipal councils was continued in the citizens, but the appointment of the burgomaster and magistrates was vested in the king from among the members of the councils. The manufactures and commerce continued to flourish and extend, and the formation of railways was actively carried on. As Holland had not yet acceded to all the conditions of the twenty-four articles, Belgium still kept possession of the whole of Limbourg and Luxembourg except the fortress of the latter, with a small area round it, which was occupied by Prussian troops. These territories had been treated in every way as a part of Belgium, and had sent representatives to both chambers. Great indignation was therefore felt at the idea of their being separated, when Holland, on 14th of March 1838, signified its readinesss to accept the conditions of the treaty. The chambers argued that Belgium had been induced to agree to the twenty-four articles in 1832 in the hope of thereby at once terminating all harassing disputes, but that as Holland did not then accept them, the conditions were no longer binding, and the circumstances were now quite changed. They urged that Luxembourg in effect formed an integral part of their territory, and that the people were totally opposed to a union with Holland. They offered to pay for the territory in dispute, but the treaty gave them no right of purchase, and the proposal was not entertained. The two chambers unanimously voted addresses to the king, expressing a hope that the integrity of Belgium would be maintained. Similar addresses were sent from all parts of the country, and the people were roused to a great state of excitement. The king was at one with his people, and every preparation was made for war. But the firmness of the allied powers, and their determination to uphold the conditions of the treaty, at last brought the king, though with extreme reluctance, to give in to their views. After violent discussions the Chamber of Representatives gave its adhesion on 19th March 1839, and some days later the Senate followed the example. The treaty was signed at London on the 19th of April. The annual payment by Belgium for its share of the national debt, which had been fixed at 8,400,000 florins, was reduced to 5,000,000 florins, or £416,666, with quittance of arrears prior to 1st January 1839. When this excitement was at its height the Bank of Brussels failed, and much misery and distress among the people was the result. This was immediately followed by the failure of the Brussels Savings-Bank, but the Government instantly came forward and guaranteed the claims thereupon, amounting to 1,500,000 florins.

[1] See Parliamentary paper, Aug. 1870,—*Netherlands, Belgium, and Luxembourg Treaties of* 1831, 1839, *and* 1867.

The Belgian revolution owed its success to the union of the Roman Catholics and the Liberals; and the king had been very careful to maintain the alliance between these two parties. This continued to be the character of the Government up to 1840, but by degrees it had been becoming more and more conservative, and was giving rise to dissatisfaction. A ministry was formed on more liberal principles, but it clashed with the Catholic aristocracy, who had the majority in the Senate. Disputes arose which caused great excitement among the people, and the cabinet resigned. A new ministry was then formed, under M. Nothomb, of a unionist or mixed kind. In 1842 a new law for the organization of public primary instruction was passed, which, however, did not meet with the approval of the clergy. In 1844 a commercial treaty was concluded with the German Zollverein; and soon after similar treaties were formed with France and Holland. The Nothomb ministry retired in 1845, and for seven months M. Van de Weyer attempted to carry on affairs with a mixed ministry; but he found it impossible to maintain harmony among the different factions. A Catholic administration was then formed, which was attacked with the greatest fury by the Liberals. The latter summoned a Liberal congress to meet at Brussels (14th June 1846), composed of delegates from the different Liberal associations throughout the country. Three hundred delegates met and deliberated with the greatest calmness, drawing up an Act of Federation and a programme of Belgian Liberalism. The elections of 1847 gave a majority in favour of the Liberals; the cabinet resigned, and a Liberal administration took its place and formally announced a new policy. Hence it happened that when next year France was in revolution and her king a fugitive, Belgium remained calm and unshaken. When the news reached Brussels the king convoked a council of his ministers and offered to resign if they thought that it would avert calamity or conduce to the public welfare. The ministers replied that a constitutional monarchy was best fitted for the people, and that a republic was neither according to their wishes nor adapted to their character. The democratic societies of Brussels attempted a revolutionary movement, but met with little success. At this time a new electoral law was issued lowering the franchise to 20 florins' worth of property (33s. 4d.), by which the number of electors was at once doubled; and soon after another law reduced the qualification for municipal councils to 46 francs (36s.) These timely concessions gave general satisfaction, and completely disarmed the extreme democratic party; so that when an expedition was organized in Paris against the throne of Leopold, with the countenance and aid of certain members of the French Government, it met with no sympathy and totally failed in its object. On the night of the 24th March the conspirators, to the number of about 800 French and 100 Belgians, arrived at Quievrain by train, but they were at once surrounded by the military and peasants and made prisoners. Alarmed at this attempt the Government strongly reinforced the frontier towns with troops, and was thus able to repulse a more formidable invasion that took place a few days later. Belgium, however, suffered severely from the shock given to commercial credit and general industry. The discounts at the bank, which in 1847 had been 160,200,000 francs, sank, in 1848, to 86,900,000 francs, and the current accounts fell from 183,000,000 francs to 96,000,000 francs. The panic soon rendered the payment of notes in cash impossible; and the Government, by a law passed 28th March 1848, suspended cash payments, and authorized the bank to issue inconvertible notes to a limited extent. By this seasonable measure public credit was restored, and industry speedily revived.

The attention of the Government was now largely directed to the stimulating of private industry and the carrying out of public works of great practical utility, as the extension of railways and the opening up of other internal means of communication. Commercial treaties were also entered into with various countries with the view of providing additional outlets for industrial products. The king also sought as much as possible to remove from the domain of politics every irritating question, believing that a union of the different parties was most for the advantage of the state. In 1850 the question of middle class education was settled. In August of that year the whole country between Brussels and the French frontier suffered greatly from excessive rains; the country for many leagues was flooded, many lives were lost, and the destruction of property was very great. On 25th September the king laid the foundation stone of a monument in Brussels to commemorate the national congress which in 1831 had fashioned the new destinies of the country, and on 11th October the queen died. In 1852 the Liberal cabinet was overthrown, and a ministry of conciliation was formed. A bill was passed authorizing the army to be raised to 100,000 men including reserve. The elections of 1854 modified the parliamentary situation by increasing the strength of the Conservatives; the ministry resigned and a new one was formed under M. de Decker, of moderate Catholics and Progressives. At the Paris conference of 1856, which settled the peace with Russia, the French minister, Count Walewski, complained of Belgium permitting to issue from its press publications the most hostile and insulting to France and her government, in which revolt and assassination were openly advocated. The remarks caused great indignation in Belgium. In 1857 violent discussions took place between the Liberal party and the Roman Catholics on the question of the administration of charities throughout the kingdom. Since 1830 the administration of these had been vested in the secular power, and the Catholic party had long sought to get this power into their own hands. When, therefore, M. de Decker, who supported their views, became head of the ministry, the priests made every exertion, even by bribery, to influence the elections so as to obtain a majority in their favour. In April the ministry of M. de Decker brought in a bill practically abolishing the existing law on the subject. The bill met with the most violent opposition; the discussions, which extended over 27 sittings and were characterized by great animosity, revealed a growing spirit of exaction and intolerance on the part of the clergy; but eventually it was carried by a majority of 60 to 41. The result caused great excitement among the people, the Liberal deputies were cheered, and the principal Catholic speakers hooted and insulted. The agitation extended to the provinces, and the military had to be called out to restore peace. Eventually the bill was withdrawn, and the ministers gave in their resignations. The elections for the communal councils gave a great majority in all the important towns in favour of the Liberals. A new Liberal ministry was formed under M. Rogier. In 1860 the communal *octrois*, or the taxes on articles of food brought into the towns, were abolished; and in 1863 the navigation of the Scheldt was made free. This last year, also, a treaty of commerce and navigation was concluded with England. The elections of July 1864 gave a majority to the Liberals in the Chamber of Representatives, and the ministry of M. Rogier continued in office.

On the 10th December 1865 King Leopold died, after a reign of 34 years. He was greatly beloved by his people, and much respected by the other sovereigns of Europe. He was repeatedly chosen to decide in international disputes; and the grievances of hostile Governments were not unfrequently submitted to him. His well-known

honesty and integrity of purpose, his reflective and well-balanced intellect, his habit of close and accurate reasoning, his grave and serious deportment, all eminently fitted him for the office of arbiter. To him Belgium owed much. In difficult circumstances and critical times he managed its affairs with great tact and judgment; by conciliatory measures he reconciled and kept at peace opposing factions; and by his well-known devotion to the best interests of the country he secured the confidence and esteem of all classes of the people. He was succeeded by his eldest son Leopold II., who was immediately proclaimed king, and took the oath to the constitution on 17th December. In 1866 a body of English volunteers, to the number of 1100, visited Belgium by invitation, and met with a most cordial reception from the king and all classes of the people, and took part in the Tir National. The following year a body of Belgian volunteers, numbering about 2400, came over to England, where they were warmly welcomed, and engaged in the shooting contests at Wimbledon. In 1868 serious riots took place in the mining districts, which were not put down till the military had been called out; the effective army was raised from 80,000 to 100,000 men, and the yearly contingent from 10,000 to 12,000. Attempts were also made to obtain a revision of the elementary education law of 1842.

On the outbreak of the war between France and Germany in 1870, Belgium saw the difficulty and danger of her position, and lost no time in providing for contingencies. A large war credit was voted, the strength of the army was raised, and large detachments were moved to the frontier. The feeling of danger to Belgium also caused great excitement in England, particularly after the contents of the secret treaty—which revealed the aggrandizing schemes of France against Belgium—became known. The British Government declared its intention to maintain the integrity of Belgium in accordance with the treaty of 1839, and it induced the two belligerent powers to sign treaties to that effect. In the event of either power violating the neutrality of Belgium, England was to co-operate with the other in such manner as might be mutually agreed upon to secure the integrity of the country. It was at first feared that Belgian territory might be violated by the necessities of one or other of the belligerents, but this was not the case. A considerable portion of the French army routed at Sedan did, indeed, take refuge in Belgian territory; but they laid down their arms according to convention, and were "interned" in the king's dominions.

In 1870 the Liberal party, who had been in power for thirteen years, was overthrown by a union of the Catholics with the Radicals or Progressionists, joined by not a few Liberals, to whom the opposition of the Government to certain reforms had given offence. A ministerial crisis followed, which was terminated by the advent to office of a Catholic cabinet, at the head of which was Baron d'Anethan. A new election took place in August 1870, which gave them a majority in both houses,—a result brought about in no small degree by the excitement consequent on the breaking out of the Franco-German war. The Baron d'Anethan steered his course prudently, and increased the power of the Ultramontanes considerably by carrying a reform bill, which widened the basis of representation as regarded the provincial and communal councils, by introducing large masses of the Catholic lower orders to the privilege of the franchise. It added nearly one-half to the number of electors for the provincial councils, and more than a fourth to those for the communal councils. The Liberals were very much dissatisfied; and towards the end of the year the mob in Brussels took up the question, and tumults broke out which the police and civic guard had to put down by force. They demanded the dismissal of the ministers, to which the king at length consented; and a new ministry was formed under M. de Theux. The communal elections of 1872 were the occasion of a sharp struggle throughout the kingdom between the church party and the Liberals, but success remained chiefly with the latter. The elections of June 1874 resulted in a considerable reduction of the Ultramontane majority within the Senate and the Chamber of Representatives, without actually converting it into a minority. In July of that year a conference of representatives of the leading powers of Europe was held in Brussels, with the view of introducing certain changes in the usages of war, but no definite result was arrived at. In May and June 1875, religious disturbances broke out in various parts, which were attended with serious consequences. At Brussels, Ghent, and other places, religious processions, which partook of the character of party demonstrations, were attacked by mobs of the populace, and many persons were injured. These disturbances were only put a stop to by energetic measures on the part of those in authority, and the infliction of severe punishments on the delinquents.

The attention of foreign states has of late been particularly directed to Belgium, in consequence of certain remonstrances addressed to it by Germany on the subject of its international relations and its duties towards foreign powers. This arose from an obscure Belgian, named Duchesne, having written to a French archbishop, offering to assassinate Prince Bismarck for a consideration. He was taken and tried by the Belgian Government, but it was found that the law had provided no punishment for the offence which he had committed. This led to a remonstrance on the part of the German Government, which was couched in such terms as to afford ground for the gravest fears, on the part of Belgium and of foreign states, as to what might be the result. The correspondence, however, was carried on in a friendly spirit on both sides, satisfactory explanations followed, and the Belgian Government passed a measure making such offences as that of Duchesne criminal.

(D. K.)

BELGRADE (in Servian, *Bielgorod*, or White Town), the capital of the Servian principality, situated at the confluence of the Save and the Danube, on the right bank of the latter stream, opposite the Austrian town and fortress of Semlin Lat. 44° 47′ N., long. 20° 28′ E. It is built both on, and at the side of, a northern spur of the Avala heights, the rocky summit being crowned by its once famous citadel, which still remains very much as it was left by Prince Eugene, except that on the E., S., and W. the glacis has been changed into a promenade. The town was formerly divided into three parts, namely, the Old Town, the Rassian Town (*Sava mahala* or Save-district), and the Turkish town (*Dorcol*, or Cross-road). A great change has, however, taken place in the course of the present century, and the old divisions are only partially applicable, while there has to be added the

Tirazia, an important recent suburban extension along the line of the aqueduct or *Tirazi*. Since 1869 great activity has been shown in building, and the Old Town is gradually being regulated according to a definite plan. The general appearance of the place is growing more and more European; its mosques and minarets, protected from actual demolition by a Turkish treaty, are falling into ruin from neglect. As the seat of the Servian Government, and the residence of the prince and the archbishop, Belgrade possesses a royal and an episcopal palace, a foreign and a home office, and other public buildings. Its educational institutions are remarkably numerous, consisting of a high school, several normal schools, a gymnasium, a theological seminary, a military academy, an industrial school, and an upper school for girls. There is a theatre devoted to the development of the national drama; and in the same building with the high school there is preserved a valuable collection of national antiquities as well as an extensive library. Besides the mosques, the ecclesiastical buildings include a cathedral and several Greek churches, a Roman Catholic chapel in the Austrian embassy, and an evangelical church. Among places of historical interest are the ruins of Prince Eugene's palace, and the monument in the Topjidere park on the spot where Prince Michael was assassinated in 1868. The citadel has been already mentioned; a commandant's residence, barracks, and a military hospital are among its subsidiary buildings. Though its situation is highly conducive to mercantile activity, the commerce of Belgrade is not so great as would naturally be anticipated. It holds, however, direct commercial relations not only with Vienna and Constantinople but with Manchester. There are only two monetary establishments, one known as the "First Bank," and the other a bank of credit. The principal industrial products of the city are cotton-stuffs, carpets, leather, and fire-arms. Belgrade is identified with the ancient *Singidunum*, and was the station of the *Legio IV. Flavia Felix*. It has from its earliest existence been a place of military importance, and in modern times has sustained many sieges, and repeatedly passed from the hands of the Austrians to those of the Turks. It was taken by Soliman II. in 1521, and retaken by the Austrians in 1688, but again lost in 1690. In 1717 it surrendered to Prince Eugene. The imperialists retained it till 1739, when the Turks invested and reduced it. Austria again took it in 1789, but it was restored at the peace of 1791. In the year 1806 the Servian insurgents succeeded in carrying it. In 1862 it was bombarded from the citadel on account of a contest raging between the Turkish and Servian inhabitants, but five years later it was completely evacuated by the foreign forces, and the citadel received a garrison of Servian soldiers. The only mark of Turkish occupation is the banner which continues to be shown from its walls along with the national colours. Population in 1872, 26,674.

BELIEF (*πίστις*, *Fides*, *Foi*, *Glaube*), with its synonyms Assurance, Confidence, Conviction, Credence, Trust, Persuasion, Faith, is in popular language taken to mean the acceptation of something as true which is not known to be true, the mental attitude being a conviction that is not so strong as certainty, but is stronger than mere opinion. For the grounds of such conviction, ordinary language refers at once to probable as opposed to intuitive or demonstrative evidence. Such popular phrases do not, of course, amount to a definition of belief; but this is not to be expected from them, especially if, as may be laid down with some confidence, no logical definition of the process be possible. It may be described and marked off from similar or contrasted states, but a rigidly scientific definition of what appears to be a simple, ultimate fact is not attainable. The general explanation, however, is so far unsatisfactory in that it throws no light upon the most interesting question with regard to belief, its province, and does not tell us what are the objects of belief as opposed to those of knowledge. To answer this it is necessary to describe somewhat more minutely the mental process under examination.

1. Unfortunately for purposes of analysis, the word belief is used in a variety of relations which seem at first sight to have but little in common. We are said to believe in what lies beyond the limits of our temporal experience, in the supersensible, in God and a future life. Again, we are said to believe in the first principles or ultimate verities from which all trains of demonstration must start; as conditions of demonstration, these are themselves indemonstrable, and are therefore objects of belief.[1] We receive by belief perceptions of single matters of fact, which from their very nature cannot be demonstrated.[2] We believe from memory the facts of past experience; we have expectation or belief in future events. We accept truths on the evidence of testimony; and finally, we believe that our actual consciousness of things is in harmony with reality. From this unsystematic arrangement of objects of belief it will be possible to eliminate certain classes by noting in the first instance what we are not said to believe, but to know. By knowledge may be understood generally the conviction of truth which rests on grounds valid for all intelligence, and which is expressed in propositions necessary both for our thinking and for reality. At the same time we are commonly and correctly said to know states of consciousness when they are immediately present, together with their differences, similarities, connections, and relations to self. Whatever is necessarily connected with present experience, and can be logically deduced from it, is also matter not of belief but of knowledge. Again, we know all propositions of apodictic certainty, such as those of mathematics and logic. Mathematical propositions carry us beyond mere thinking; the laws which flow from the relations of space and time are not only thought but known to be true of all objects of sensible experience, for no objects whatsoever can form part of that experience save under these quantitative conditions. It is therefore an error to say that we believe abstract mathemetical laws apply to objects; we know this with absolute certainty. So also our cognizance of logical principles, such as the laws of identity and contradiction, is matter of knowledge, of insight, not of belief. It would appear, therefore, that knowledge extends to facts immediately present in consciousness, and to certain relations true of all facts of sensible experience; but in neither of these classes of cognition does there seem to be given an absolute guarantee for the *existence* of any fact which is not immediately before us. That one object presented to us is known seems to give no actual knowledge that another object ideally connected with it has at the same time real being. Mathematical and logical laws are absolutely true of all experience to which they apply, but this truth gives no certainty that there will be experience. If there be objects of experience at all, they must be subject to mathematical and logical law; but the question remains, is there any ground, absolutely necessary and compelling assent, for holding that there will be such experience.[3] This is an old matter of debate; it lies at

[1] This has been pointed out by a long line of thinkers, from Aristotle to Jacobi and Hamilton.

[2] So knowledge through the senses is called *Offenbarung* by Jacobi and Lotze (*Mikrokosmus*, iii. 548).

[3] *Cf.* Lotze, *Mik.*, iii. 547. "When one affirms that every object of thought is identical with itself, that the same under the same conditions has the same consequences, under different conditions different consequences, that a cause precedes every effect,—all these are universal truths, which tell us, indeed, what must be or take place if there should

the very root of the distinction between knowledge and philosophical belief, and leads directly into the deepest problems of metaphysical science, its solution depending upon the answer given to the doubt whether or not our thinking is merely formal, receiving materials and working them up in forms which may have no correlates in reality. Hume, who in this connection has given the impulse to all subsequent British thinking, laid his finger with unerring precision on the crucial point, and deliberately relegated all *matters of fact* to the province of belief. According to him, knowledge never passes beyond immediate intuition of ideas and their relations. Whenever we touch upon real existence, past or future, belief, not knowledge, is our instrument. An adequate discussion of the difficulty would lead beyond the limits of the present inquiry; it may suffice to indicate generally what can be said on one typical point of the debate. Is the supposition of a causal connection among phenomena merely belief, or is it a necessary condition of knowledge? If the latter, then our thinking carries us with apodictic certainty beyond present experience of facts, for every causal judgment is, *ipso facto*, universal, and therefore extends to all or any time. Now, no proof of the universality of law among phenomena can ever be given from empirical grounds, for all such attempts virtually involve the very principle in question. It is a necessary presupposition, without which knowledge would be impossible. Its contrary is certainly not self-contradictory, if by self-contradiction be meant impossibility of representation, for chaos can be pictured; but the power of imagination is surely not the criterion of truth. It is the power of knowing objects that is in question, and the non-existence of the causal relation among phenomena would render actual experience impossible. Objects cannot be known save under this supposition. A similar line of argument directed towards others of the notions involved in what Kant has called synthetical judgments *a priori*, would show that such notions are constitutive of our experience, that thought penetrates deeply into phenomena, and that phenomenal relations are but types of the forms of real cognition. It might, of course, still be maintained that all these synthetical propositions are only formal,—are only true if experience be given,—and that a wide field is still left for belief. Under certain conditions this may be admitted. A doubt as to the very existence of experience is hardly a valid argument, but that there should be specific connections of phenomena, permanent and constant—that, for example, the same cause should continue to have the same effects—may seem not quite a matter of knowledge. The real element of doubt in such a case is not, however, whether the same cause under the same conditions shall give the same effects, but whether in any definite instance we have attained a thorough knowledge of the cause itself, and whether the conditions will recur. The first of these doubts is overcome in the ordinary progress of knowledge; the other concerns the empirical appearance of the effects, relates therefore to what may be called the contingent, and forms the object of belief.

It follows from what has been said that we exclude from the province of belief primitive truths and facts of immediate experience, with such phenomena, past or future, as are connected causally or by rational links with facts immediately known. There is still a wide field left for belief. (*a*.) In the stage of knowledge which we call sensible cognition belief introduces itself; for consciousness, which unhesitatingly affirms the correspondence of its content with reality, readily exhibits its falsity when submitted to analysis. The belief, though firm, is shown to be erroneous,—to be merely the rapid summation of a number of signs, which themselves do not come clearly before consciousness, and are therefore accepted without examination. (*b*.) In memory of our own past experience belief is involved. When I remember, I have present to consciousness ideas which represent past reality. To have ideas simply is to imagine; to have ideas which we are convinced represent past experience is to have imagination *plus* belief, *i.e.*, to remember. It should be observed that we are frequently said to trust our memory, to believe that what we remember is true. This phraseology is objectionable; we cannot properly be said to *trust* our memory, we simply use it. In the very fact of remembering is involved the reference to past reality which is the essence of belief. (*c*.) We believe testimony, *i.e.*, we accept as true facts not in our experience, and which possibly may never be. In this case our belief is, that under certain conditions we should have the experience which from the testimony we can picture to ourselves. (*d*.) Expectation, so far as merely contingent elements are concerned, is a pure case of belief.

2. So far as we have yet seen, all objects of belief have been or may be objects of knowledge; and the most prominent distinction between the two is the presence in the one of an actual intuition and its absence in the other. This distinction, however, as we have pointed out, is not absolute; all thinking of reality is not belief. Belief is rather the thinking of reality which is determined by grounds not necessarily valid for all intelligence, but satisfactory for the individual thinker. The difference between imagination and the thought of some reality does not seem capable of further analysis; it expresses an ultimate fact. Attempts, however, have been made to work out a psychology of belief, and to point out the characteristics differentiating ideas believed in from mere pictures of the mind. These have been generally due to British thinkers; and, since the time of Hume, the problem has become one of considerable importance. Locke, who marked out very carefully the province of belief and considered its grounds, made no attempt to analyse the state itself. Hume,[1] however, puts the question clearly before himself and returns an unhesitating answer. "As it is certain," he says, "there is a great difference betwixt the simple conception of the existence of an object and the belief of it, and as this difference lies not in the parts or composition of the idea which we conceive, it follows that it must be in the manner in which we conceive it. When we are convinced of any matter of fact, we do nothing but conceive it along with a certain feeling, different from what attends the reveries of imagination." "This feeling is nothing but a firmer conception or a faster hold that we take of the object." "This *manner* of conception arises from a customary conjunction of the object with something present to the memory or senses." From the last sentence to the elaborate theory of James Mill is but a short step. According to Mill, belief is a case of constant association; an idea is believed which is irresistibly called up in connection with present experience. Thus in memory, the ideas of the past experience are irresistibly associated with the idea of myself experiencing them, and this irresistibility constitutes belief. Expectation, again, is the irresistible suggestion by present experience of a consequent or train of consequents. And to memory and expectation all ordinary cases of belief may be reduced.

Both these theories are defective in the same point,—the analysis of what is meant by object in general, and, consequently, of what is involved in thinking of an object. Hume's is open to the special objection that he makes the

be a case of their application, but which tell us nothing of the real existence of any case."

[1] A theory somewhat similar to that of Hume is worked out by Mr Bagehot, *Contemporary Review*, April 1871.

difference between the believed and imagined idea the same as that between impression and idea, which is an ultimate distinction, and yet holds the difference to be merely one of degree. In Mill's account of memory it may be pointed out that the ideas of *past* experience, and of myself as having had the experience, contain in themselves the very element which is supposed to be got out of their conjunction. With regard to expectation it is clear that ideas irresistibly suggested by present experience are by no means necessarily believed, and further, that many of our beliefs do not arise from any such association. J. S. Mill,[1] who subjects the association theory of belief to a searching examination, comes to the conclusion that the distinction between thinking of a reality and representing to ourselves an imaginary picture is ultimate and primordial. With his opinion later investigators, as Mr Sully,[2] concur.

Professor Bain, in opposition to other psychologists, holds that belief is not so much an intellectual state as a "phase of our active nature, otherwise called the will." "It is a growth or development of the will under the pursuit of intermediate ends." When, for instance, we perform certain acts as means towards a desired end with as much vigour as if we were realizing the end itself, "we are in a very peculiar situation, not implied in desire." This situation is belief, which is essentially "an anticipation of the pleasure" of attaining the end. Belief being a form of activity, our primitive state is one of complete confidence. The mind is filled with its present experience, and confidently believes that the future will resemble it. Ideas are so strongly taken up by the mind that they are accepted as real, and influence the will. The various disappointments of this primitive confidence gives rise to definite avoidances of certain actions, and to pursuit of others, in order to escape pain or gain pleasure. Action directed towards these intermediate ends involves, or rather is, belief. This theory has to explain expectation and memory. With regard to the first, "we make light of the difference between the conceived future and the real present;" or in other words, "we are disposed to act in any direction where we have never been checked." Our primitive disposition to act is equivalent to full expectation. It may be pointed out that this explanation throws no light on expectation of events in which our activity could by no possibility be involved. But the theory seems to break down entirely when applied to memory. There is first to be explained the fact of memory, and then it has to be shown how reference to activity is contained in it. "In surrendering our mind to the idea still remaining, and so imparting a momentary quasi-reality, we have an experience possessing the characteristic features of present reality." "We really make no radical difference between a present and a proximate past." This, in the first place, would apply only to certain cases of memory. Secondly, imparting a quasi-reality is not an explanation of the peculiar phenomenon of an idea representing the past. It is an error, even on Professor Bain's own principles (see note to *Mill's Analysis*, i. 342; *Emotions and Will*, 2d ed. 525), to speak of *belief* in a present reality, while here memory is explained as a pseudo-realization of the ideas. Nor is he more successful in referring memory to activity. To identify my remembrance of having run up against a wall to avoid a carriage with the conviction that, should such a danger recur, I should again run up against the wall (see *Emotions and Will*, 2d ed., 554), is absurd. The whole theory seems but an instance of a not uncommon error in psychology,—the confusion of the test or measure of a thing with the thing itself. Belief is truly a motive to action,[3] and all that has been said of it by Professor Bain would hold good of it in this relation; to identify the two is to run together totally distinct processes.

Modern German psychology has not approached the problem of belief from the same side as the English. Beneke alone, by his analysis of *tact* (see *Lehrbuch der Psych.*, § 158, and *System der Logik*, i. 268, *seq.*), has opened up a somewhat fresh vein of thinking. His hints have been carried out by Germar (*Die alte Streitfrage, Glauben oder Wissen*, 1856), who gives the following definition of belief: "If the consciousness (of the truth of what we think) arises from *tact*, and therefore without consciousness of the factors or grounds through which it is produced, it is called belief; it is elevated to knowledge when these factors are brought before consciousness" (p. 58).[4] In general the example of Kant has been followed, who looked upon the question as belonging not so much to psychology as to the theory of knowledge. His own discussion of the subject and his distinction between *Meinen*, *Glauben*, and *Wissen* have powerfully influenced later thought. According to him, *Glaube* (belief in the sense of *Fides* as opposed to *Credulitas*, *Foi* as opposed to *Croyance*) should be confined to such propositions as rest on grounds subjectively not merely sufficient but necessary; that is to say, the propositions believed in are recognized as the demands of our moral or practical reason, and their truth can never be disproved, for such disproof would be radically inconsistent with the moral nature which we are conscious of possessing. Our confidence in their truth is unwavering and practical, *i.e.*, leading to action; for without them we could not act in conformity with our moral nature. Nevertheless, of the objects of such propositions we can never have scientific knowledge.

3. Kant's distinction of *Meinung* and *Glaube* leads us directly to the one species of belief which has not yet been considered. All objects of belief, so far as has yet appeared, might come within our temporal experience; but we are said to believe in the supersensible, which from its very definition seems to surpass experience and, consequently, knowledge. To such belief the name *faith* is properly restricted, and in its nature it differs somewhat from the belief hitherto discussed. There is not, of course, included in it the specifically theological notion of faith as *Fiducia* (*quæ est apprehensio meriti θεανθρώπου appropriativa ad me et te in individuo*); it corresponds rather to the *Notitia* and *Assensus*, which are also elements in theological faith, and may be defined as the subjective expression of man's relation to God. When understood in this sense, religious belief is by no means a mere feeling, though it contains feeling as one of the stages in its development, for mere feeling is in itself blind and valueless, whereas faith is intelligent or rational. Nor is it a blank faith which would have the same value whatever were the objects believed in, for religious belief has a definite content; it is the acceptation of certain facts and truths and the active realization of them. As its content is definite (for if it were not so, the religions of Christ and of Mahomet, of Buddha and of Zoroaster, would stand on the same level, all having subjective faith or conviction), belief of necessity involves knowledge, rational construction of the facts believed. Faith is but the lower stage of completed insight, and in its own development follows the natural order of progress in knowledge, which begins with feeling and intuition, rises through concrete representation into logical connection,

[1] Notes to J. Mill's *Analysis*, i *Cf. Dissertations*, iii.

[2] *Sensation and Intuition.* (On the Development of Belief.)

[3] It is so defined by Bain (*Ment. and Moral Sc.*, 372), who finds great difficulty in reconciling his theory with ordinary phraseology. Such an expression as the following has a curious ring:—"Belief is identical with the activity or active disposition, at the moment, and with reference to the thing *believed*."—(Note to *Analysis*, i. 395.)

[4] With this view may be compared much of what is said by J. H. Newman, *Grammar of Assent*; see specially 73, 281.

and finally culminates in rational cognition. So religious belief, which is primarily little more than a vague feeling of something over and beyond the present state of existence, combined with the dim sense of our own finite and dependent condition, gradually rises to a higher stage, and in its efforts to attain some cognizance of the supersensible, begins even to attach itself to natural objects. But as it can find in these no satisfaction, it is compelled to construct some representations of the supernatural which shall harmonize with our spiritual wants. In the formation of these religious ideas we are not left without help, nor are they to be looked upon as mere figments of the mind. The revelation which has been given in nature, both physical and moral, and in the special experience to which the name is more frequently applied, furnishes matter which is laid hold of and pressed into the service. Religious belief or faith always attaches itself to representations, intuitions, or facts; it gives what Newman has called Real as opposed to Notional Assent. But it is not the less necessary that faith should be raised to insight, and that we should construe in terms of thought what religious experience brings before us as direct intuition. There must be theology as well as religion. Nothing is believed which is not held to be so connected with the rational nature of man as irretrievably to injure that nature should its truth be overthrown. This is not to put knowledge in place of faith, if knowledge be understood to apply only to the logically necessary; nor is it to assert that what have been called truths of revelation could have been discovered by natural reason. Knowledge, however, cannot be confined to the abstract understanding; and nothing is more delusive than the total opposition of revelation and reason. "What is there in the nature of things," says Augustine, "that God has done unreasonably?" To affirm that reason does not of itself discover the truths of revelation, is simply to bring against it the reproach it may well bear, that it does not create experience. Reason has not to make new facts, but to accept given experience, and evolve from it the pure elements of thought which it contains, and in which its truth consists. Faith, therefore, precedes knowledge, as Anselm used to say; but its priority is that of time, not of authority.[1]

4. There remains to be taken into account the interesting question of the grounds and motives for belief. It is, of course, necessary to distinguish between these two; the *cause* of a belief may not be exactly a *reason* for it. Belief, though natural, is not always rational, but frequently rests with happy unconsciousness on foundations utterly inadequate to its support. But if we disregard this distinction and include both causes and reasons under the title principles of belief, these may be divided into three classes —(1), Testimony; (2), Feelings, Desires, or Wishes; (3), Evidence of Reason. These are rarely dissevered in actual practice. Testimony, to the reception of which the name belief is frequently restricted, is familiar enough to require no extended notice. Our natural tendency is to accept all testimony as true; it is experience alone that teaches caution. Where from the nature of the case no such experience is to be had, credulity settles down into firm and ineradicable conviction. The majority of men would be astonished to find how much their belief depends upon the society into which they have been born and in which they live. Dogmas at first forced upon a people gradually become ingrained in the minds of those brought up in habitual contact with them. There is hardly a limit to the possibility of instilling beliefs through continued custom, and no resistance to analysis is so strong as that offered by mere customary opinion, which has imperceptibly introduced itself into the very life's blood of those who share it.

The feelings, though not so directly a source of convictions as testimony, exercise an extensive and complex influence on belief. It has always been a popular saying that a man believes what he wishes—that "the wish is father to the thought;" and there can be no doubt that the superior force given to an idea by the concentration on it of desire or affection, causes it to bulk so largely in consciousness as to exclude the thought of its non-realization. The very idea of a result opposed to what we earnestly desire is unpleasant enough to make us resolutely shut it out of sight. This, however, is but a partial and limited effect. We know very well that our belief is only occasionally swayed by our wishes, and that necessity too often constrains us to believe what we willingly would not. Our volition cannot directly compel belief. But the feelings play a more important part; for it is by their means primarily that we stretch beyond the field of direct knowledge and complete our limited experience with what we feel to be necessary for the harmony of our moral and religious nature. We believe that without which our nature would be dissatisfied, and this belief takes its rise in the feelings,—the blind expressions of intellectual want,—which form the first stage towards completed insight.

It is hardly necessary to do more than refer to the rational grounds for belief. Wherever our knowledge of any object or law is incomplete, belief is ready to step in and fill up the gap by some hypothesis, which is in conformity with our experience, is rationally connected with the facts to be explained, and is not yet known to be true. Great portions of our so-called scientific knowledge are nothing but rational belief,—hypotheses unverified, perhaps even unverifiable,—and the settlement of the conditions or legitimacy of such presumptions forms the principal part of inductive logic.

Besides the works already referred to, the following treat of belief in general:—Fechner, *Drei Motive und Grunde des Glaubens*, 1863; Ulrici, *Glauben und Wissen, Spekulation und exacte Wissenschaft*, 1858; of religious belief in particular, in addition to works on dogmatic theology or philosophy of religion:—Schwarz, *Das Wesen der Religion*, 1847; Asher, *Der religiose Glaube*, 1860; J. Kostlin, *Der Glaube*, 1860; Venn, *Hulsean Lectures for* 1869. (R. AD.)

BELISARIUS (Sclavonic, *Beli-tzar*, "White-Prince"), the greatest general of the Byzantine empire, was born about 505 A.D., at Germania, on the borders of Illyria. As a youth he served in the body-guard of Justinian, who appointed him commander of the Eastern army. He won a signal victory over the Persians in 530, and successfully conducted a campaign against them, until forced, by the rashness of his soldiers, to join battle and suffer defeat in the following year. Recalled to Constantinople, he married Antonina, a profligate, daring woman. During the sedition of the "green" and "blue" parties of the circus he did Justinian good service, effectually crushing the rebels who had proclaimed Hypatius emperor. In 533 the command of the expedition against the Vandal kingdom in Africa, a perilous office, which the rest of the imperial generals shunned, was conferred on Belisarius. With 15,000 mercenaries, whom he had to train into Roman discipline, he took Carthage, defeated Gelimer the Vandal king, and carried him captive, in 534, to grace the first triumph witnessed in Constantinople. In reward for these services Belisarius was invested with the consular dignity, and medals were struck in his honour. At this time the Ostrogothic kingdom, founded in Italy by Theodoric the Great, was shaken by internal dissensions, of which Justinian resolved to avail himself. Accordingly, Belisarius invaded Sicily; and, after storming Naples and defending Rome for a year against almost the entire strength of the Goths in Italy, he concluded the war by the capture of

[1] See Scotus Erigena, *De Divis. Natur.*, i, 69.

Ravenna, and with it of the Gothic king Vitiges. So conspicuous were Belisarius's heroism and military skill that the Ostrogoths offered to acknowledge him Emperor of the West. But his loyalty did not waver; he rejected the proposal and returned to Constantinople in 540. Next year he was sent to check the Persian king Nushirvan; but, thwarted by the turbulence of his troops, he achieved no decisive result. On his return to Constantinople the intrigues of Antonina, whom he had confined on account of her illicit amours, caused him to be stripped of his dignities and condemned to death, and he was only pardoned by humbling himself before his imperious consort. The Goths having meanwhile reconquered Italy, Belisarius was despatched with utterly inadequate forces to oppose them. Nevertheless, during five campaigns his strategic skill enabled him to hold his enemies at bay, until he was removed from the command, and the conclusion of the war entrusted to his rival Narses. Belisarius remained at Constantinople in tranquil retirement until 559, when an incursion of Bulgarian savages spread a panic through the metropolis, and men's eyes were once more turned towards the neglected veteran, who placed himself at the head of a mixed multitude of peasants and soldiers, and repelled the barbarians with his wonted courage and adroitness. But this, like his former victories, stimulated Justinian's envy. The saviour of his country was coldly received and left unrewarded by his suspicious sovereign. Shortly afterwards Belisarius was accused of complicity in a conspiracy against the emperor; his fortune was confiscated, and himself flung into prison. His last years are shrouded in uncertainty, as they are not dealt with in the circumstantial history of Procopius; but he seems to have been liberated and reinstalled in the enjoyment of his hard-won honours before his death in 565. The fiction of Belisarius wandering as a blind beggar through the streets of Constantinople, which has been adopted by Marmontel in his *Bélisaire*, and by various painters and poets, seems to have been invented by Tzetzes, a writer of the 12th century. Gibbon justly calls Belisarius the Africanus of New Rome. But for his successes, which were achieved with most insignificant means, the effete Byzantine empire would have been dismembered among Vandals, Persians, and Goths. He was merciful as a conqueror, stern as a disciplinarian, enterprising and wary as a general; while his courage, loyalty, and forbearance seem to have been almost unsullied. Like Corbulo, the faithful general of Nero, he was suspected and persecuted by an ungrateful master; and, like him, he restored the old discipline to the troops and the ancient lustre to the Roman arms in a corrupt and nerveless age. (*Cf.* Mahon's *Life of Belisarius*; Finlay's *Greece under the Romans*; Procopius; Gibbon's *Decline and Fall*, ch. 41-43.)

BELIZE, the capital of British Honduras, and the only trading-port in the colony. It is situated on the sea-coast, at the mouth of a river of the same name, in lat. 17° 29′ N. and long. 88° 8′ W. It consists of one principal street along the shore with a number of offshoots, is for the most part well built, and has a governor's house, a fort, a court-house, a jail, a Gothic church, a hospital, and a number of schools. The exports are principally mahogany, rosewood, cedar, logwood, cocoa-nuts, fustic, and sugar. In 1872, 379 vessels, most of them British, with a total tonnage of 32,345 tons, entered the port. Regular steamboat communication has been established with Kingston, Jamaica. The population is about 5000.

BELKNAP, Jeremy, an American clergyman and author, was born at Boston in 1744 and died in 1798. He was educated at Harvard University, where he graduated in 1762. In 1767 he was called to a Congregational church in Dover, New Hampshire, and remained there for twenty years. He then removed to the Federal Street church in Boston, which he held till his death. His principal works are—*History of New Hampshire*, 3 vols., 1784-92; *American Biography*, 2 vols., 1794-98; *The Foresters*, 1792.

BELL (from Ang. Sax. *bellan*, to resound, akin to *peal*), an open percussion instrument varying in shape and material, but usually cup-like or globular and metallic, so constructed as to yield one dominant note. This definition excludes on the score of sound the cauldrons of Dodona (*Dodonæi lebetes* of the Greek oracular temples), and also the Chinese or Indian gongs, and, on the score of shape, all drums, cymbals, the metal plates of the Romans, and resonant bars of metal or wood still used by many savage tribes.

Antiquaries have worried themselves and their readers about the antiquity of bells and to small purpose. It is doubtful whether the bells of gold (Exod. xxviii. 32, 35) were anything but jangling ornaments of some kind worn by the high priest; but Mr Layard believes that he has found some small bronze bells in the palace of Nimroud. We may gather generally that small bells long preceded large ones, which latter, however, were used in India and China long before they were known in Europe.

The Romans used bells for various purposes. Lucian, 180 A.D., mentions an instrument (*Clepsydra*) mechanically constructed with water, which rang a bell as the water flowed to measure time. Bells summoned the Romans to the public baths; they were also used in processions, and so passed naturally into the service of the Western Church. The first recorded application of them to churches is ascribed by Polydore Vergil to Paulinus (*circa* 400 A.D.) He was bishop of Nola, a city of Campania (hence *nola* and *campana*, the names of certain bells). It has been maintained that Pope Sabinianus, 604, first used church bells; but it seems clear that they were introduced into France as early as 550. In 680 Benedict, abbot of Wearmouth, imported them from Italy; and in the 7th century, Bede mentions them in England. St Dunstan hung many in the 10th century; and in the 11th they were not uncommon in Switzerland and Germany. It is incredible that the Greek Christians, as has been asserted, were unacquainted with bells till the 9th century; but it is certain that, for political reasons after the taking of Constantinople by the Turks, in 1453, their use was forbidden, lest they should provide a popular signal for revolt.

Several old bells are extant in Scotland, Ireland, and Wales; the oldest are often quadrangular, made of thin iron plates hammered and riveted together. Dr Reeves of Lusk described in 1850 St Patrick's bell preserved at Belfast, called *Clog an eadhachta Phatraic*, "the bell of St Patrick's will." It is 6 inches high, 5 broad, 4 deep, adorned with gems and gold and silver filgiree-work; it is inscribed 1091 and 1105, but is probably alluded to in Ulster annals in 552. For Scotch bells, see *Illustrated Catalogue of Archæological Museum*, Edinburgh, for 1856.

The four-sided bell of the Irish missionary St Gall, 646, is preserved at the monastery of St Gall, Switzerland. In these early times bells were usually small; even in the 11th century a bell presented to the church at Orleans weighing 2600 ℔ was thought large. In the 13th century larger bells were cast. The bell, Jacqueline of Paris, cast 1400, weighed 15,000 ℔; another Paris bell of 1472, 25,000 ℔; and the famous Amboise bell at Rouen, 1501, 36,364 ℔. But there we have reached the threshold of the golden age of bells, of which more anon.

Before we enter on the history and manufacture of the bell in Europe it is worth while to enumerate the different kinds of bells named by Hieronymus Magius in his work *De Tintinnabulis*:—1. *Tintinnabulum*, a little bell, otherwise called *tinniolum*, for refectory or dormitory, according to Belethus, but Durandus names *equilla* for the

refectory; 2. *Petasius*, or larger "broad-brimmed hat" bell; 3. *Codon*, orifice of trumpet, a Greek hand-bell; 4. *Nola* (see *ante*), a very small bell, used in the choir, according to Durandus; 5. *Campana* (see *ante*), a large bell, first used in the Latin churches in the steeple (Durandus), in the tower (Belethus); 6. *Squilla*, a shrill little bell. We read of *cymbalum* for the cloister (Durandus), or *campanella* for the cloister (Belethus); *nolula* or *dupla* in the clock; *signum* in the tower. There was also a bell called *corrigiuncula*, to summon the monks at scourging time.

We shall now give a brief account of the manufacture of the bell proper, *i.e.*, the church bell of the last five centuries. It must not be supposed that the early bell-founders understood all the principles of construction, mixture of metals, lines, and proportions which go to form our notion of a good bell. As the Amati or Stradiuarius violin is the result of innumerable experiments extending over centuries, so the bells of Van den Gheyn (1550) and Hemony (1650) disengaged themselves after ages of empirical trials as the true models, and supplied the finished type for all succeeding bell-workers.

Bell-metal is a mixture of copper and tin in the proportion of 4 to 1. In Henry III.'s reign it was 2 to 1. In Mr Layard's Nineveh bronze bells, it was 10 to 1. Zinc and lead are used in small bells. The thickness of the bell's edge is 1·15th of its diameter, and its height is twelve times its thickness.

Bells, like viols, have been made of every conceivable shape within certain limits. The long narrow bell, the quadrangular, and the mitre-shaped in Europe at least indicate antiquity, and the graceful curved-inwardly-midway and full trumpet-mouthed bell indicates an age not earlier than the 16th century.

The bell is first designed on paper according to the scale of measurement. Then the crook is made, which is a kind of double wooden compass, the legs of which are respectively curved to the shape of the inner and outer sides of the bell, a space of the exact form and thickness of the bell being left betwixt them. The compass is pivoted on a stake driven into the bottom of the casting-pit. A stuffing of brickwork is built round the stake, leaving room for a fire to be lighted inside it. The outside of this stuffing is then padded with fine soft clay, well mixed and bound together with calves' hair, and the inner leg of the compass run round it, bringing it to the exact shape of the inside of the bell. Upon this *core*, well smeared with grease, is fashioned the false clay bell, the outside of which is defined by the outer leg of the compass. Inscriptions are now moulded in wax on the outside of the clay-bell; these are carefully smeared with grease, then lightly covered with the finest clay, and then with coarser clay, until a solid *mantle* is thickened over the outside of the clay bell. A fire is now lighted, and the whole baked hard; the grease and wax inscriptions steam out through holes at the top, leaving the sham clay bell baked hard and tolerably loose, between the *core* and the *cope* or *mantle*. The cope is then lifted, the clay bell broken up, the *cope* let down again, enclosing now between itself and the *core* the exact shape of the bell. The metal is then boiled, and run molten into the mould. A large bell will take several weeks to cool. When extricated it ought to be scarcely touched, and should hardly require tuning. This is called its maiden state, and it is one so sought after that many bells are left rough and out of tune in order to claim it.

A good bell, when struck, yields one note, so that any person with an ear for music can say what it is. This note is called the *consonant*, and when it is distinctly heard the bell is said to be "true." Any bell of moderate size (little bells cannot well be experimented upon) may be tested in the following manner:—Tap the bell just on the curve of the top, and it will yield a note one *octave* above the consonant. Tap the bell about one quarter's distance from the top, and it should yield a note which is the *quint* or fifth of the octave. Tap it two quarters and a half lower, and it will yield a *tierce* or third of the octave. Tap it strongly above the rim where the clapper strikes, and the quint, the tierce, and the octave will now sound simultaneously, yielding the consonant or key-note of the bell.

If the tierce is too sharp the bell's note (*i.e.*, the consonant) wavers between a tone and a half-tone above it; if the tierce is flat the note wavers between a tone and a half-tone below it; in either case the bell is said to be "false." A sharp tierce can be flattened by filing away the inside of the bell just where the tierce is struck, but if the bell when cast is found to have a flat tierce there is no remedy. The consonant or key-note of a bell can be slightly sharpened by cutting away the inner rim of the bell, or flattened by filing it a little higher up inside, just above the rim. (See H. R. Haweis's *Music and Morals*, 5th edition, p. 429.)

The quality of a bell depends not only on the casting and the fineness and mixture of metals, but upon the due proportion of metal to the calibre of the bell. The larger the bell the lower the tone; but if we try to make a large E bell with metal only enough for a smaller F bell, the E bell will be puny and poor. It has been calculated that for a peal of bells to give the pure chord of the ground tone or key-note, third, fifth, and octave, the diameters are required to be as thirty, twenty-four, twenty, fifteen, and the weights as eighty, forty-one, twenty-four, and ten.

The history of bells is full of romantic interest. In civilized times they have been intimately associated, not only with all kinds of religious and social rights, but with almost every important historical event. Their influence upon architecture is not less remarkable, for to them indirectly we probably owe all the most famous towers in the world. Grose in his *Antiquities* observes, "Towers at first scarcely rose above the roof, being intended as lanterns for the admission of light, an addition to the height was in all likelihood suggested on the more common use of bells."

Bells early summoned soldiers to arms, as well as citizens to bath or senate, or Christians to church. They sounded the alarm in fire or tumult; and the rights of the burghers in their bells were jealously guarded. Thus the chief bell in the cathedral often belonged to the town, not to the cathedral chapter. The curfew, the Carolus, and St Mary's bell in the Antwerp tower all belong to the town; the rest are the property of the chapter. He who commanded the bell commanded the town; for by that sound, at a moment's notice, he could rally and concentrate his adherents. Hence a conqueror commonly acknowledged the political importance of bells by melting them down; and the cannon of the conquered was in turn melted up to supply the garrison with bells to be used in the suppression of revolts. Many a bloody chapter in history has been rung in and out by bells.

On the third day of Easter 1282, at the ringing of the Sicilian vespers, 8000 French were massacred in cold blood by John of Procida, who had thus planned to free Sicily from Charles of Anjou. On the 24th of August, St Bartholomew's day, 1571, bells ushered in the massacre of the Huguenots in France, to the number, it is said, of 100,000. Bells have rung alike over slaughtered and ransomed cities; and far and wide throughout Europe in the hour of victory or irreparable loss. At the news of Nelson's triumph and death at Trafalgar, the bells of Chester rang a merry peal alternated with one deep toll, and similar

striking incidents could be indefinitely multiplied. It was, however, in the low countries of Belgium and Holland, distracted with incessant civil wars, that, for purely political reasons, bells acquired unique importance.

But their religious and civil uses may be further noticed. The Ave Mary bell tolled at 6 and 12 to remind men of prayer to the Virgin; the vesper bell for evening prayer; the compline was for the last service of the day. The sanctus, often a handbell, rung at the sacrifice of the mass; the passing bell, at death. The curfew (*couvre feu*), introduced by the Conqueror into England, rang at 8 o'clock to extinguish all lights. In many parts of the country and in university towns at 8 and 6 o'clock bells are still rung. At Antwerp cathedral we find the *Cloche de Triomphe*, by Dumery; sixteen bells at Sotteghem and several at Ghent and elsewhere bear the same maker's name. The Horrida, or ancient tocsin at Antwerp, said to date from 1316, is long-shaped and is now unused. The curfew in the same tower rings at 5, 12, and 8. The Santa Maria ($4\frac{1}{2}$ tons) first rang when Carl the Bold entered Antwerp 1467. St Antoine is another celebrated bell, and the favourite Carolus, given by Charles V. ($7\frac{1}{2}$ tons), is made of copper, silver, and gold, and valued at £20,000. At Strasburg we have the Holy Ghost bell, with motto, "O Rex gloriæ Christæ veni cum pace," and date 1375, 3 nonas Augusti (8 tons), only rung when two fires are seen in the town at once. The recall or storm bell warns travellers in the plain of the storm coming from the Vosges Mountains. The Thor or gate bell, for shutting and opening gates of the city, has been cast three times (1618, 1641, and 1651); it bears the following inscription:—

"Dieses Thor Glocke das erst mal schallt
Als man 1618 sahlt
Dass Mgte jahr rognet man
Nach doctor Luther Jubal jahr
Das Bos hinaus das Gut hinein
Zu lauten soll igr arbeit seyn."

The Mittags, or 12 o'clock bell, taken down in the French Revolution, bore the motto—

"Vox ego sum vitæ
Voco vos—orate—venite."

From all this it will appear that these Continental bells acquired a strong personality from the feelings and uses with which they were associated; and, indeed, they were formally christened with more ceremony than we give to christening our ships, and were then supposed to have the power of driving away evil spirits, dispersing storms, &c.

Bell-founding attained perfection in Holland in the 16th and 17th centuries; and the names of Hemony, Dumery, and the Van den Gheyns stand out as the princes of the art. Their bells are still heard throughout the Low Countries, and are plentiful at Amsterdam, Bruges, Ghent, Louvain, Mechlin, and Antwerp. These bells are frequently adorned with bas reliefs of exquisite beauty, such as feathers, forest leaves, fruit, flowers, portraits, or dancing groups, and inscribed with Latin, sometimes bad, but strong, quaint, and often pathetic. We give the preference to Hemony's small bells, and to Van den Gheyns's large ones. The names of Deklerk, Claes Noorden and Johann Albert de Grave (1714), Claude and Joseph Plumere (1664), Bartholomew Goethale (1680), and Andrew Steiliert (1563) also occur in Belgium. The following illustrate the nature of inscriptions and mottoes common in Belgium:—"Non sunt loquelæ neque sermones audiantur voces eorum, F. Hemony, Amstelodamia, 1658;" "Laudate Domini omnes gentes, F. Hemony, 1674;" and on a Ghent bell—

"Mynem naem is Roelant
Als ick clippe dan ist brandt
Als ick luyde dan is storm in Vlænderland."

A common inscription runs—

"Funera plango, Fulgura frango, Sabbata pango,
Excito lentos, Dissipo ventos, Paco cruentos."

A few other inscriptions which occur on bells in France and England may be quoted. The bell in the cathedral at Rouen, already mentioned, which was melted down by the Revolutionists in 1793, bore the words—

"Je suis George d'Ambois
Qui trente cinque mille pois
Mais lui qui me pesera
Trente six mille me trouvera."

Bells of the parish church at Winnington, Bedfordshire, had—

"Nomina campanis hæc indita sunt quoque nostris."
1st bell.—"Hoc signum Petri pulsatur nomine Christi."
2d „ "Nomen Magdalene campana sonat melode."
3d „ "Sit nomen Domini benedictum semper in eum.
4th „ "Musa Raphaelis sonat auribus Immanuelis."
5th „ "Sum Rosa pulsata mundique Maria vocata."

By an old chartulary it appears that the bells of the Priory of Little Dunmow, in Essex, were in the year 1501 new cast and baptized—

"Prima in honore Sancti Michaelis Archangeli.
Secunda in honore Sancti Johannis Evangelisti.
Tertia in honore S. Johannis Baptisti.
Quarta in honore Assumptionis beatæ Mariæ.
Quinta in honore sanctæ Trinitatis et omnium sanctorum."

In the little sanctum at Westminster, Edward III. built a clocher, and placed in it bells for St Stephen's chapel, round the largest of which was cast—

"King Edward made mee thirtye thousand weight and three,
Take me down and wey mee,
And more you shall fynd mee."

Some of the music played on the carillon clavecin is still extant. We may specially mention the *morceaux fugués* discovered by the Chevalier van Elewyck, in the archives at Louvain, the work of the celebrated organist and carilloneur Matthias van den Gheyn (published by Schott and Co., Brussels and London). This music is as fine in its way as Bach or Handel.

Quite lately several carillons have been put up in England; and one (1875) is in contemplation for St Paul's cathedral. The new carillon machinery by Messrs Gillett and Bland of Croydon, now employed almost everywhere in connection with clocks and carillons, is incomparably superior to anything of the kind on the Continent. By its aid the hammer, which falls on the outside of the bell, is raised mechanically instead of by the action of the fist or finger on the key; and all that the stroke on the key does is to let it slide off like a hair-trigger, and drop on the bell. Thus the touch of the modern carillon clavecin bids fair to rival that of the organ. The same firm has also invented a bell piano. The chief carillons in England at present are at Boston church, Lincolnshire, Worcester cathedral, Bradford town-hall, Rochdale town-hall, and Shoreditch. Several good peals of bells in London are immortalized in the common nursery rhyme—

"Gay go up and Gay go down,
To ring the bells of London town."

Bell-ringing by rope is still a popular art in England. The first regular *peal* of bells in this country was sent in 1456 by Pope Calixtus III. to King's College, Cambridge, and was for 300 years the largest peal in England. At the beginning of the 16th century sets of eight bells were hung in a few large churches. In 1668 a famous work on bells, *Tintinalogia*, by T. W. [White], appeared, introducing a sort of bell-notation by printing the bells 1, 2, 3, 4, &c., on slips of paper in different orders according to the changes rung. Of these changes there is a great variety, spoken of technically as hunting, dodging, snapping, place-making, plain-bob, bob-triple, bob-major, bob-major reversed, double bob-major, grandsire-bob-cator, &c.

The following numbers show how three bells can ring six changes:—1, 2, 3; 1, 3, 2; 2, 1, 3; 2, 3, 1; 3, 1, 2; 3, 2, 1. Four bells ring four times as many as three, *i.e.*. twenty-four; five bells ring five times as many as four, or 120. And it may thus be shown that it would take ninety-one years to ring all the changes upon twelve bells at two strokes a second; whilst twenty-four bells would occupy more than 117 billions of years!

Bell-ringing is conducted as follows:—Ropes hang through holes in the bell-chamber, and are usually fastened to a wheel for leverage, round which the rope passes. There is a great knack in handling the rope. The first half-pull "drops" the bell, the second "sets" it; it next swings up to the slur-bar, then it swings down and up to the other side, the clapper striking as it ascends. Eight bells make the most perfect peal, tuned in the diatonic scale.

Bells are struck in three ways,—(1) with a hammer on the outside, let off either by a tambour or revolving drum, similar in appearance to the prickly cylinder of a musical box, which drum can be fitted with tunes or chimes by musical nuts or spikes, and altered at will; (2) the bell can also be struck by hand, as in the common stand of small bells to be seen occasionally in the London streets, the player having a hammer in each hand; or (3) the clapper may strike the bell internally, either being pulled by a rope, the bell being stationary, or by the bell swinging to and fro. If the hammer or clapper be too light the tone of the bell is not properly drawn; if too heavy it will pulverize or crack the bell in time.

Great reforms are needed in the hanging of bells, a subject to which the Americans have given much attention. What Messrs Gillett and Bland are in England with reference to carillon machinery, the Meneelys of New York are to the ordinary mechanism and hanging of bells. There is hardly a cathedral tower in England where the hanging of one or more bells, or the oscillation of the tower, is not justly complained of. When a bell is hard to ring it is usually on account of its hanging. The leverage is wrongly applied; the wood-work is crowded against the masonry, and many of the finest towers have thus become unsafe.

There are a few bells of world-wide renown, and several others more or less celebrated The great bell at Moscow, *Tzar Kolokol*, which, according to the inscription, was cast in 1733, was in the earth 103 years, and was raised by the Emperor Nicholas in 1836. The present bell seems never to have been actually hung or rung, having cracked in the furnace. Photographs of it are now common, as it stands on a raised platform in the middle of a square. It is used as a chapel. It weighs about 440,000 lb; height, 19 feet 3 inches; circumference, 60 feet 9 inches; thickness, 2 feet; weight of broken piece, 11 tons. The second Moscow bell, the largest in the world in actual use, weighs 128 tons. The great bell at Peking weighs 53 tons; Nanking, 22 tons; Olmutz, 17 tons; Vienna (1711), 17 tons; Nôtre Dame (1680), 17 tons; Erfurt, one of the finest bell metal, 13 tons; Great Peter, York Minster, which cost £2000 in 1845, 10 tons; St Paul's, 5 tons; Great Tom at Oxford, 7 tons; Great Tom at Lincoln, 5 tons. Big Ben of the Westminster clock tower (cracked) weighs between 13 and 14 tons; it was cast by George Mears under the direction of Edward Beckett Denison in 1858. Its four quarters were cast by Warner in 1856. The Kaiserglocke of Cologne cathedral, lately recast (1875), weighs 25 tons.

On the varied uses past and present of small bells a volume might be written. Octaves of little bells have been introduced into organs and utilized in the orchestra. Handringers are still common throughout the country—one man with a bell fitted with a clapper, in each hand, ringing but two notes of the tune in his turn. Upright stands of bells without clappers, struck with wands, may often be seen in the streets. Bells for horses, dogs, cows, sheep, &c., have already been alluded to. In Italy and elsewhere they are often made of baked earth; these have a very sweet sound, and cost about a penny. For sledges and harness they are of metal, and worn usually in bunches. A bunch of twelve costs about two francs. On the Italian lakes and elsewhere a bell fixed to a floating cork marks the spot where lines or nets are laid for fish. Hunting-hawks were formerly supplied with small bells to facilitate recovery.

Whilst some uses of bells have gone out, new ones have come in. A few instances will give the reader some idea of the indefinite number of services to which they have been applied. The expression to curse with book, bell, and candle, alludes to an old form of exorcism, in which the bell was used to scare the evil spirit—a function also attributed to larger bells. Bearing the bell alludes to the prize of a silver bell usually given at horse-races to the winner; hence comes what is, after all, only the bell reversed and used as a drinking vessel—the prize cup. The diving-bell no more comes within the scope of the present article than the dome of a mosque. Certain uses of small bells are fast disappearing. The dustman's bell is now seldom heard. The town-crier, with his "Oh, yes" (*oyez*, hear ye), has been banished to the provinces. The 5 o'clock postman, with his hand-bell to collect letters, went out when the present postal system came in. On the other hand the muffin-bell, the railway-bell, the dock-bell, the half-hour bells at sea, and the stage-bell survive; whilst new applications, unknown to our forefathers, have been introduced. Few people are aware that house-bells worked with wires are scarcely 100 years old. Long before them, no doubt, handbells had to a great extent superseded the use of the horn, whistle, rattle, clapping of hands, and hammering on the door with a stick, and fire-bells were in frequent use. The old bell-pulls, which still linger in country inns and mansions, have been replaced by spring handles in the walls, and these are disappearing from hotels and clubs in favour of electric bells, now so common in railway stations in connection with the telegraph. A current of electricity sets a small hammer in motion, and, in the dark, the stream of sparks between the hammer and bell is clearly visible. In a word, then, it is plain that the whole of civilized life is set to bell music in one shape or another; and although the more important uses of bells have been enumerated, time would fail to mention all their lowly but not less useful functions,– such as the familiar dinner-bell, yard-bell, school-bell, factory-bell, jail-bell, small portable cupola spring-bell (pressed with the hand), spring signal door-bell (used in shops), safety-bell on swinging coil (fastened to shutters or doors); and, not to forget the nursery, the coral and bells, bell-rattles—which call to mind, and are probably relics of, the old fool's cap and bells and fool's wand with its crown of jingling baubles, or it may be that the fool's baubles are copies of the child's playthings.

The Rev. H. T. Ellacombe, author of various works on bells, gives in his *Chiming* a complete catalogue of bell literature. (H. R. H.)

BELL, Dr Andrew, a clergyman of the Church of England well known for his philanthropic efforts in the cause of education, and more particularly for his success in extending the monitorial system of instruction in schools, was born at St Andrews in 1753. He graduated at the university of that town, and afterwards spent some years in America. In 1789 he was chaplain at Fort St George, and minister of St Mary's church, Madras. While in this position he occupied himself with instructing the orphan children of the military asylum, and having been obliged **Dr A. Bell.**

from scarcity of teachers to introduce the system of mutual tuition by the pupils, found the scheme answer so well that he became convinced of its universal applicability. In 1797, after his return to London, he published a small pamphlet explaining his views. No public attention was drawn towards the plan till the following year, when Mr Joseph Lancaster, a dissenter, opened a school in Southwark, conducting it in strict accordance with Bell's principles. The success of the method, and the strong support given to Lancaster by the whole body of dissenters, gave immense impetus to the movement. Similar schools were established in great numbers; and the members of the Church of England, becoming alarmed at the patronage of these schools resting entirely in the hands of dissenters, resolved to set up similar institutions in which church principles should be inculcated. In 1807 Dr Bell was called upon to organize a system of schools in accordance with these views. For his valuable services he was in some degree recompensed by his preferment to a prebend of Westminster, and to the mastership of Sherborn Hospital, Durham. He died in 1832 at Cheltenham, and was buried in Westminster Abbey. His great fortune was bequeathed almost entirely for educational purposes. Of the £120,000 given in trust to the provost of St Andrews, two city ministers, and the professor of Greek in the university, half was devoted to the founding of the important school, called the Madras College, at St Andrews; £10,000 was left to each of the large cities, Edinburgh, Glasgow, Leith, Inverness, and Aberdeen, for school purposes; and £10,000 was also given to the Royal Naval School. (See Southey's *Life of Dr Bell.*)

Sir C. Bell. BELL, SIR CHARLES, K.H., the youngest son of the Rev. William Bell, a clergyman of the Episcopal Church of Scotland, was born at Edinburgh, November 1774. His mother Margaret Morice, the elder daughter of an Episcopal clergyman, was remarkable for her piety and general accomplishments, and she exercised a powerful influence over her gifted sons. The father, William Bell, after a life of contending with difficulties, died on 20th of September 1779, aged seventy-five, leaving his wife and six children very slenderly provided for. Of these six children, three became distinguished men, namely, John Bell, the anatomist and surgeon; George Joseph Bell, professor of the law of Scotland in the University of Edinburgh; and Charles Bell, the subject of this notice. After having studied two years at the High School and two years more at the University of Edinburgh, Charles embraced the profession of medicine and devoted himself chiefly to the study of anatomy, under the direction of his brother John, who was twelve years older, and who had already earned a reputation as an anatomist and surgeon. Regarding his early education, he wrote, in 1839, on a copy of Pettigrew's *Medical Portrait Gallery*, opposite a remark that he had been educated at the High School,—"Nonsense! I received no education but from my mother, neither reading, writing, ciphering, nor anything else." At school and college he does not appear to have distinguished himself, except by his facility in drawing, a hereditary gift acquired from his mother. It was not until he entered on the study of anatomy that he gave evidence of possessing those talents which soon made him a worthy rival of his brother John.

His first work, entitled *A System of Dissections, explaining the Anatomy of the Human Body, the manner of displaying the Parts, and their Varieties in Disease*, was published in Edinburgh in 1798, while the author was still a pupil. The "Introduction" to this work shows much originality of thought, and an aptitude for devising new methods of preparing animal structures for dissection and demonstration. The volume is illustrated by numerous engravings from original drawings, and the text is clear and precise in language. For many years this work was considered to be a valuable guide to the student of practical anatomy.

On the 1st of August 1799 he became a fellow of the Royal College of Surgeons of Edinburgh. At that time the fellows of the college were in rotation surgeons to the Royal Infirmary of Edinburgh. In this position Bell soon gave evidence of great ability. He dissected, drew, described, mounted preparations of anatomical, physiological, or pathological value, improved on the modes of operating in surgery known at that time, and invented a method of making models of morbid parts, of which specimens may still be seen in the museum of the college.

In 1802 he published a series of engravings of original drawings, showing the anatomy of the brain and nervous system. These drawings are remarkable for artistic skill and finish. They were taken from dissections made by Bell for the lectures or demonstrations he gave on the nervous system as part of the course of anatomical instruction of his brother. In 1804 he wrote volume iii. of *The Anatomy of the Human Body*, by John and Charles Bell. This volume contains the anatomy of the nervous system, and of the organs of special sense.

In 1804 a new arrangement was made regarding the attendance of surgeons at the Edinburgh Infirmary; and Bell, probably as being junior in the profession, was excluded from the hospital. He proposed to the managers to pay £100 a year, and to transfer to them, for the use of the students, the museum he had collected, on condition that he should be "allowed to stand by the bodies when dissected in the theatre of the infirmary, and to make notes and drawings of the diseased appearances." This enthusiastic proposal was rejected, and the consequence was that Bell went to London in November 1804.

From that date, for nearly forty years, he kept up a regular correspondence with his brother George, much of which has recently been published (*Letters of Sir Charles Bell, &c.*, 1870). The earlier letters of this correspondence show how rapidly he rose to distinction in a field where success was difficult, as it was already occupied by such men as Abernethy, Sir Astley Cooper, and Cline. He quickly made acquaintance with most of the scientific men of the day, and apparently won friends in the highest social, professional, and artistic circles. After having lodged in Fludyer Street for some months, he settled in Leicester Street, Leicester Square, and immediately commenced a course of lectures on anatomy and surgery. Here he also located his museum, which was sent to him from Edinburgh; and his letters indicate that this was the subject of much interest to scientific and professional men. He lectured to painters, directed private dissections, gave demonstrations to surgeons, and gradually acquired a surgical practice.

Before leaving Edinburgh in 1804, he had written his work on the *Anatomy of Expression*. It was published in London soon after his arrival, and at once attracted attention. His practical knowledge of anatomy and his skill as an artist qualified him in an exceptional manner for such a work. The object of this treatise was to describe the arrangements by which the influence of the mind was propagated to the muscular frame, and to give a rational explanation of the muscular movements which usually accompany the various emotions and passions. One special feature of the author's system was the importance attributed to the respiratory arrangements as a source of expression. He also showed how the physician and surgeon might derive information regarding the nature and extent of important diseases by observing the expression of bodily suffering. This work, apart from its value to artists and psychologists, is of interest historically, as there is no doubt the investigations of the author into the nervous supply of the muscles of expression induced him to prosecute inquiries which led to

his great discoveries in the physiology of the nervous system.

In 1807 Bell first published his idea of a new anatomy of the brain, in which he announced the discovery of the different functions of the nerves corresponding with their relations to different parts of the brain. It is now difficult to imagine the confusion which prevailed in the minds of anatomists and physiologists regarding the functions of the various nerves prior to this discovery. The nerves had been noticed by anatomists from the earliest times, and they were divided into cranial and spinal nerves, according as they originated from the brain or spinal cord. Some were supposed to carry from the brain the mandates of the will, while others communicated to the sensorium impressions made on their extremities, which resulted in consciousness. It was supposed, however, that the same nerve, even at the same time, might in some mysterious way transmit either motor or sensory impressions in opposite directions. When a nerve was cut, the parts beyond the incision were found to be destitute of sensibility, and to be beyond the influence of the will. It was consequently correctly inferred to be the cord through which volition acted on the muscles, and through which sensory impressions were transmitted to the sensorium. The idea of two sets of filaments functionally different in the same nerve was not then entertained. Boerhaave asserted that there were two kinds of spinal nerves, the one serving for motion and the other for the use of the senses. Haller states, "I know not a nerve which has sensation without also producing motion." The first Monro held a similar opinion, and he believed all those spinal nerves which passed through a ganglion to be motor nerves.

To Sir Charles Bell we owe the discovery that in the nervous trunks there are special sensory filaments, the office of which is to transmit impressions from the periphery of the body to the sensorium, and special motor filaments which convey motor impressions from the brain or other nerve centre to the muscles. He also showed that some nerves consist entirely of sensory filaments and are therefore sensory nerves, that others are composed of motor filaments and are therefore motor nerves, whilst a third variety contains both kinds of filaments and are therefore to be regarded as sensory-motor. Furthermore, he indicated that the brain and spinal cord may be divided into separate parts, each part having a special function—one part ministering to motion, the other to sensation, and that the origin of the nerves from one or other or both of those sources endows them with the peculiar property of the division whence they spring. He also demonstrated that no motor nerve ever passes through a ganglion. Lastly, he showed both from theoretical considerations and from the result of actual experiment on the living animal, that the anterior roots of the spinal nerves are *motor*, while the posterior are *sensory*. These discoveries as a whole must be regarded as the greatest in physiology since that of the circulation of the blood by the illustrious Harvey. It not only was a distinct and definite advance in scientific knowledge, but from it flowed many practical results of much importance in the diagnosis and treatment of disease. It is not surprising that Bell should have announced it to his friends with exultation. On 26th November 1807 we find him writing as follows to his brother George:—"I have done a more interesting *nova anatomia cerebri humani* than it is possible to conceive. I lectured it yesterday. I prosecuted it last night till one o'clock; and I am sure it will be well received." On the 31st of the same month he writes—"I really think this new anatomy of the brain will strike more than the discovery of the lymphatics being absorbents."

In 1807 he produced a *System of Comparative Surgery* founded on the basis of anatomy. This work indicates the author's idea of the science of surgery. He regarded it almost wholly from an anatomical and operative point of view, and there is little or no mention of the use of medicinal substances. It placed him, however, in the highest rank of English writers on surgery.

In 1809 he relinquished his professional work in London, and rendered meritorious services to the wounded from Coruña, who were brought to the Haslar Hospital at Portsmouth. In 1810 he published a series of *Letters concerning the Diseases of the Urethra*, in which he treated of stricture from an anatomical and pathological point of view.

In 1812 he was appointed surgeon to the Middlesex Hospital, and a few years afterwards professor of anatomy, physiology, and surgery to the College of Surgeons of London. He was also for many years teacher of anatomy in the school of Great Windmill Street, no longer in existence. He acted as surgeon to the hospital for twenty-four years, and delivered many courses of lectures on surgery in that institution. In 1815 he did good public service by devoting all his skill and time to the wounded after the battle of Waterloo. On the formation of University College, Gower Street, he was asked to place himself at the head of the medical department. This appointment he held for only a short time, when he resigned in consequence, it is said, of dissensions in the senate.

In 1816, 1817, 1818, he published a series of *Quarterly Reports of Cases in Surgery, treated in the Middlesex Hospital, in the Cancer Establishment, and in Private Practice, embracing an Account of the Anatomical and Pathological Researches in the School of Windmill Street.* In 1821 he issued a volume of coloured plates with descriptive letterpress, entitled *Illustrations of the Great Operations of Surgery, Trepan, Hernia, Amputation, and Lithotomy.* In 1824 appeared *An Exposition of the Natural System of Nerves of the Human Body; being a Republication of the Papers delivered to the Royal Society on the subject of the Nerves.* In the same year he wrote *Observations on Injuries of the Spine and of the Thigh Bone.* In 1832 he wrote a paper for the Royal Society of London on the "Organs of the Human Voice," in which he gave many illustrations of the physiological action of these parts.

Of an eminently pious and reflective mind, he was often in the habit of pointing out in his lectures what he regarded as evidences of creative design to be found in the anatomy of the bodies of animals. These he embodied in a treatise on *Animal Mechanics*, written for the Society for the Diffusion of Useful Knowledge. The executors of the earl of Bridgewater selected him as a fit person to maintain the argument which it was the purpose of that nobleman's bequest to have published. Sir Charles wrote in 1833—*The Hand: its Mechanism and Vital Endowments as evincing Design.* Along with Lord Brougham he annotated and illustrated an edition of Paley's *Natural Theology*, published in 1836, in which he followed out his favourite line of thought.

The Royal Society of London awarded to him in 1829 the first annual medal of that year given by George IV. for discoveries in science; and when William IV. ascended the throne, Charles Bell received the honour of knighthood along with a few other men distinguished in science and literature.

The chair of surgery in the University of Edinburgh was offered to him in 1836. When the offer was made he was regarded as one of the foremost scientific men in London, and he had a large surgical practice. But his opinion was "London is a place to live in, but not to die in;" and he accepted the appointment. In Edinburgh he did not earn great local professional success; and, it must be confessed,

he was not appreciated as he deserved. But honours came thick upon him. On the Continent he was spoken of as greater than Harvey. It is narrated that one day Roux, a celebrated French physiologist, dismissed his class without a lecture, saying "C'est assez, Messieurs, vous avez vu Charles Bell." He held the Edinburgh chair from 1836 to 1842. During his professorship, in 1838, he published the *Institutes of Surgery, arranged in the order of the Lectures delivered in the University of Edinburgh;* and in 1841 he wrote a volume of *Practical Essays*, two of which "On Squinting," and "On the Action of Purgatives," are of great value.

Sir Charles Bell died at Hallow Park near Worcester on Thursday, 28th April 1842, in his sixty-eighth year; and he lies under the yew tree in the peaceful churchyard of Hallow. His epitaph, written by his life-long friend Lord Jeffrey, summarizes his character as follows:—"Sacred to the memory of Sir Charles Bell, who, after unfolding, with unrivalled sagacity, patience, and success, the wonderful structure of our mortal bodies, esteemed lightly of his greatest discoveries, except only as they tended to impress himself and others with a deeper sense of the infinite wisdom and ineffable goodness of the Almighty Creator. He was born at Edinburgh 1774; died, while on a visit of friendship, at Hallow park, in this parish, 1842; and lies buried in the adjoining churchyard." (J. G. M.)

George J. Bell. BELL, George Joseph, brother of the preceding, was born at Edinburgh on the 20th of March 1770. At the age of eight he entered the High School, but he received no university education further than attending Tytler's lectures on civil history, Stewart's course of moral philosophy, and Hume's lectures on the law of Scotland. He became a member of the Faculty of Advocates in 1791, and was one of the earliest and most attached friends of Francis Jeffrey. In 1804 he published a *Treatise on the Law of Bankruptcy in Scotland*, in 2 vols. 8vo, which was gradually enlarged in subsequent editions, till at length a fifth edition was published in 1826, in 2 vols. 4to, under the title of *Commentaries on the Law of Scotland and on the principles of Mercantile Jurisprudence*—an institutional work of the very highest excellence, which has guided the judicial deliberations of his own country till the present time, and has had its value acknowledged by such eminent jurists as Story and Kent. In 1821 he was unanimously elected professor of the law of Scotland in the University of Edinburgh; and in 1831 he was appointed to one of the principal clerkships in the Supreme Court. He was in 1833 placed at the head of a commission to inquire into the expediency of making various improvements in the Scottish bankruptcy law; and in consequence of the reports of the commissioners, chiefly drawn up by himself, many beneficial alterations have been made in this department of the law. He died on the 23rd September 1843. A seventh edition of the *Commentaries*, edited by J. Maclaren, advocate, appeared in 1870. Bell's smaller treatise, *Principles of the Law of Scotland* (6th edit. 1872), has long been a standard text-book for law students. The *Illustrations of the Principles* is also a work of high value.

BELL, Henry, a mechanical engineer, well known for his successful application of steam-power to the propulsion of ships, was born at Torphichen, in Linlithgowshire, in 1767. Having received the ordinary education of a parish school, he was apprenticed to his uncle, a millwright, and, after qualifying himself as a ship-modeller at Bo'ness, went to London, where he found employment under Rennie, the celebrated engineer. Returning to Scotland in 1790, he first settled as a carpenter at Glasgow and afterwards removed to Helensburgh, on the Firth of Clyde, where his wife superintended a large inn, together with the public baths, while he pursued his mechanical projects, and also found occasional employment as an engineer. It was not until January 1812 that he gave a practical solution of the difficulties which had beset all previous experimenters, by producing a steamboat (which he named the "Comet,") of about 25 tons, propelled by an engine of three-horse power, at a speed of seven miles an hour. Although the honour of priority, by about four years, is admitted to belong to Robert Fulton, an American engineer, there appears to be no doubt that Fulton had received very material assistance in the construction of his vessel from Bell and others in this country. A handsome sum was raised for Bell by subscription among the citizens of Glasgow; and he also received from the trustees of the River Clyde a pension of £100 a year. He died at Helensburgh, 14th November 1830, and a monument was erected to his memory at Dunglass, near Bowling, on the banks of the Clyde.

BELL, Henry Glassford, was born at Glasgow in 1805, and received his education at the High School of that city. He afterwards studied at Edinburgh and became intimate with Moir, Hogg, Wilson, and others of the brilliant staff of *Blackwood's Magazine*, to which he was drawn by his political sympathies. In 1828 he became editor of the *Edinburgh Literary Journal*, which proved unsuccessful. He passed to the bar in 1832. In 1836 he competed unsuccessfully against Sir William Hamilton for the chair of logic and metaphysics in Edinburgh University, and three years afterwards was appointed sheriff-substitute of Lanarkshire, an office which he held until 1867, when he succeeded Sir Archibald Alison in the post of sheriff-principal of the county. During his early life he had been a versatile author of poems and prose sketches, but his literary activity was checked after he applied himself seriously to law. In 1831 he published *Summer and Winter Hours*, a volume of poems, of which the best known is that on Mary Queen of Scots. He further defended the cause of the unfortuate queen in a prose *Life*. A preface which he wrote to the works of Shakespeare contains some acute and original criticism. His *Romances and other Poems* (1866) display deeper thought and less fervour than his former works, but are mainly interesting as evidence of latent poetic genius, the development of which was prevented by attention to other pursuits. Bell's literary tastes did not affect his industry in his profession, and, on the other hand, his legal labours never dulled his early affection for poetry and painting. He deserves to be held in kindly remembrance for his readiness to assist youthful literary aspirants. During many years he took an active interest in social questions, especially in promoting educational and sanitary reforms. He died in January 1874. H. G. Bell.

BELL, John, of Antermony, a Scottish traveller in the first half of the last century, was born in 1691, and educated for the medical profession, in which he took the degree of M.D. In 1714 he set out for St. Petersburg, where, through the introduction of a countryman, he was nominated medical attendant to Valensky, recently appointed to the Persian embassy, with whom he travelled from 1715 to 1718. The next four years he spent in an embassy to China, passing through Siberia and the great Tartar deserts He had scarcely rested from this last journey when he was summoned to attend Peter the Great in his perilous expedition to Derbend and the Caspian Gates. The narrative of this journey he has enriched with interesting particulars of the public and private life of that remarkable prince. In 1738 he was sent by the Russian Government on a mission to Constantinople, to which, accompanied by a single attendant who spoke Turkish, he proceeded, in the midst of winter and all the horrors of a barbarous warfare, returning in May to St. Petersburg. It appears that after this he was for several years established as a merchant at Constantinople, where he marriea John Bell

in 1746. In the following year he retired to his estate of Antermony in Scotland, where he spent the remainder of his life. He died in 1780. His travels, published at Glasgow, in two vols. 4to, 1763, were speedily translated into French, and widely circulated in Europe.

BELL, JOHN, anatomist and surgeon, was born at Edinburgh, 12th May 1763. He had the merit of being the first in Scotland who applied with success the science of anatomy to practical surgery. While still a young man he established, in the face of much opposition, an anatomical theatre in Surgeon Square, where he attracted large audiences by his admirable lectures on anatomy, physiology, and surgery, in which he was assisted by his younger brother Charles. After his exclusion from the infirmary (to which reference has been made in the notice of Sir Charles Bell), he ceased to lecture, and devoted his time to study and practice. He died at Rome in 1820, while on a tour in Italy for the benefit of his health. To great skill in his profession he united high and varied mental abilities and extensive learning.

His principal works are:—*Anatomy of the Human Body*, 3 vols. 8vo, 1793-1802; *Discourses on the Nature and Cure of Wounds*, 2 vols. 8vo, 1793-95; *Principles of Surgery*, 3 vols 8vo, 1801; and several volumes of Engravings illustrative of Human Anatomy. His *Observations on Italy* were published by his widow in 1825.

Robert Bell.

BELL, ROBERT, editor of the *Annotated Edition of the British Poets*, was an Irishman by birth and education, but a Londoner by a long residence of nearly forty years. He was born at Cork in 1800, and was educated at Trinity College, Dublin. With the tasks of a subordinate in a Government office at Dublin he combined literary pursuits, editing a political journal and contributing to periodicals. In 1828 he settled in London, and literature was thenceforward the business of his life. As journalist he edited the *Atlas* for several years; and afterwards the *Monthly Chronicle, Mirror*, and *Home News*. Of his early undertakings the more important were the volumes which he compiled for Lardner's *Cabinet Cyclopædia*, including the *Lives of British Admirals*, in continuation of Southey's work; *Lives of British Poets*; a *History of Russia*; and the continuation of Sir James Mackintosh's *History of England*. He made himself favourably known as a novelist by *The Ladder of Gold* and *Hearts and Altars*. Among his other works are a *Life of Canning, Wayside Pictures in France, Belgium, and Germany*, three five-act comedies, and a volume entitled *Memorials of the Civil War*, based on the *Fairfax Correspondence*. He earned a higher place and a more enduring reputation by his *Annotated Edition of the British Poets*, of which the first volume appeared in 1854. The series was carried through twenty-nine volumes. The works of each poet are prefaced by a carefully-prepared memoir, and accompanied by explanatory and illustrative notes, of a really helpful and often indispensable kind. In his earlier years Bell had taken a leading part in founding the Dublin Historical Society. In the course of his London life he became an active director of the Royal Literary Fund. He was also chosen F.S.A. In private life he was highly esteemed and warmly loved for his openheartedness, his genial temper, and his generous readiness to give aid to fellow-workers who might be in need. He died in London, at the age of sixty-seven, April 12, 1867.

BELLA, STEFANO DE LA, engraver, was born at Florence in 1610. He was apprenticed to a goldsmith; but some prints of Callot having fallen into his hands, he began to turn his attention entirely towards engraving, and studied the art under Canta Gallina, who had also been the instructor of Callot. By the liberality of Lorenzo de' Medici he was enabled to spend three years in study at Rome. In 1642 he went to Paris, where Cardinal Richelieu engaged him to go to Arras and make drawings of the siege and taking of that town by the royal army. After residing a considerable time at Paris he returned to Florence, where he obtained a pension from the grand duke, whose son, Cosmo, he instructed in drawing. He died in 1664. His productions were very numerous, amounting to over 1400 separate pieces.

BELLADONNA, DWALE, or DEADLY NIGHTSHADE (*Atropa Belladonna*), a tall bushy herb of the natural order *Solanaceæ*, growing to a height of 4 or 5 feet, having leaves of a dull green colour, with a black shining berry fruit about the size of a cherry, and a large tapering root. The plant is a native of Central and South Europe, extending into Asia, and it is also found in waste places and hedgerows of Britain, though it is a doubtful native. The entire plant is highly poisonous, and accidents not unfrequently occur through children and unwary persons eating the attractive-looking fruit. Its leaves and roots are largely used in medicine, on which account the plant is cultivated, chiefly in South Germany, Switzerland, and France. Both roots and leaves contain the poisonous alkaloid atropia, but in practice the roots only are employed for its extraction. The proportions in which atropia is present in the roots range between 0·6 and 0·25, the roots of young plants being always richest in the alkaloid. The percentage found in leaves is much more uniform, being about 0·47, and extracts and tinctures of the leaves are therefore of much more constant strength than if prepared from roots. Preparations of belladonna and atropia are used in medicine as anodynes in local nervous pains,—atropia being frequently hypodermically injected but rarely taken internally. They are also of great value in ophthalmic practice on account of their peculiar property of producing dilatation of the pupil, either when painted around or dropped into the eye. Belladonna is also used as an antispasmodic in hooping-cough and spasmodic coughs generally, and for various other medicinal purposes. A remarkable antagonism between the physiological action of atropia and the alkaloid of the calabar bean has been experimentally worked out by Dr Thomas R. Fraser (*Trans. Roy. Soc. Ed.*, 1870-1). To a more limited extent also an antagonism between atropia and morphia and other alkaloids has been established; and the researches on these substances, and on the mutual action of alkaloids generally, have been continued in experiments conducted by Dr J. G. M'Kendrick, reported to the British Medical Association in 1874.

BELLAI, or BELLAY, GUILLAUME DU, lord of Langey, a French general, who signalized himself in the service of Francis I., was born at Glatigny in 1491. He was considered the ablest captain of the time, and his great abilities as a negotiator occasioned the remark of the Emperor Charles V., that "Langey's pen had fought more against him than all the lances in France." He was sent in 1537 as viceroy into Piedmont, where he took several towns from the imperialists. His address in penetrating into the most secret designs of the enemy was extraordinary, and he spared no expense for that end. He was extremely active in influencing some of the universities of France to give a judgment agreeable to the desires of Henry VIII., when that prince wished to divorce his queen in order to marry Anne Boleyn. Langey composed several works, the most remarkable of which was the history of his own times (*Mémoires*, 1753, 7 vols.) He died in 1543, and was buried in the church of Mans, where a noble monument was erected to his memory.

BELLAMY, JACOBUS, a Dutch poet, was born at Flushing in 1757. He was apprenticed when young to a baker, but his abilities were discovered by a clergyman named De Water, who exerted himself in the boy's behalf, and obtained sufficient assistance to send him, in 1782, to

the University of Utrecht. In 1785 appeared his *Vaderlandsche Gezangen*, which at once gained him the highest reputation as a poet. Three years previously a small volume of his, *Gezangen mijner Jeugd*, published under the pseudonym *Zelandus*, had attracted considerable attention. His longest and, in the opinion of many, his best work is the poetic romance *Roosje*, 1784. Bellamy was one of the first to create a new and original literature in Holland; his songs have had wide circulation and great popularity.

BELLARMINE (Ital. BELLARMINO), ROBERT FRANCIS ROMULUS, Cardinal, Catholic theologian and polemic, was born, October 4, 1542, at Montepulciano, in Tuscany. He was destined by his father for state service, but his inclinations were too strong to be restrained, and at the age of eighteen he entered the Society of Jesus. After studying in various colleges for some years, he was appointed by the order to lecture on theology at the famous university of Louvain. His seven years' residence in the Low Countries brought him into close relations with modes of thought differing essentially from his own, and so compelled him to define his theological principles more clearly and sharply than before. On his return to Italy he received from Gregory XIII. an appointment in the newly-founded *Collegium Romanum*, and began to deliver lectures on the principal points of difference between the Roman Catholic and other forms of faith. Out of these lectures grew his famous work, *Disputationes de Controversiis Christianæ Fidei adversus hujus temporis Hæreticos* (3 vols., 1581, 1582, 1593), for long the finest polemical writing on the Catholic side, and still worthy of consideration. It was replied to at the time by Chemnitz, Gerhard, and Chamier, and continued for many years to furnish occasions of attack to Protestant theologians. So highly were Bellarmine's abilities rated, that he was selected to accompany, in the capacity of divine or theologian, the legation sent into France in 1590 by Sixtus V. In 1599 he was, much against his will, raised to the dignity of cardinal, and two years later was made archbishop of Capua. He resigned the archbishopric in 1605, being detained in Rome by the desire of the newly-elected Pope Paul V. About the same time he had a controversy with James I. of England, who, after the discovery of the Gunpowder Plot, had passed severe laws against Roman Catholics. In 1610 he published his work *De Potestate summi Pontificis in rebus Temporalibus*, directed against William Barclay, in which he asserted boldly and undisguisedly the doctrine of the Pope's temporal sovereignty. For some years before his death, which occurred at Rome, 17th September 1621, he held the bishopric of his native town. Bellarmine, whose life was a model of Christian asceticism, is one of the greatest theologians, particularly in the department of polemics, that the Romish Church has ever produced. His works, which are very numerous, are written in an easy perspicuous style. The most important are the *Disputatio de Controversiis*, the *De Potestate summi Pontificis*, *Institutiones Hebraicæ Linguæ*, *De Scriptoribus Ecclesiasticis*, *De Ascensione Mentis in Deum*. A life of Bellarmine, founded on an autobiography, was written by Fulligato, 1624.

BELLAY, JOACHIM DU, an eminent French poet and member of the Pleiad, was born late in 1524, at Lyré, on the left bank of the Loire, not far from Angers. In the absence of documents we are thrown upon the autobiographical passages in his poems for information about the events of his life, and these, fortunately, are copious. From these, and especially from the beautiful Latin elegy addressed to his friend Jean Morel, we learn that, deprived early of both his parents, he was left to the mercy of an elder brother, who allowed him to be brought up without other education than what his own ardent spirit supplied. Before he reached manhood this brother also died, and Joachim found himself at the head of the family, a vigorous, manly, but half-cultured youth. Suddenly he was struck down by illness; and, confined for many months to his bed, he softened the long hours of suffering by fervent study; he now read the Latin and Greek poets for the first time, and felt a passionate desire to imitate them in French. In 1548, having to a great measure recovered his health, he happened to meet Ronsard in an inn in Poitiers, and a friendship instantly sprang up between them that ceased only with Du Bellay's death. He joined the six poets, who, under Dorat, were forming a society, the Pleiad, for the creation of a French school of Renaissance poetry; and his first contribution to it was a prose volume, the famous *Deffence et Illustration de la Langue françoise*, which remains one of the earliest and most perfect pieces of literary criticism in existence, and overweighs in positive value much of his actual poetry. This appeared in 1549, and was followed within a twelvemonth by two volumes in verse, the *Recueil de Poésie*, and the collection of love-sonnets called *L'Olive*. The latter celebrate, in the manner of Petrarch, the loveliness of a semi-mythical mistress, understood to be a Parisienne, and by name Viole, of which Olive is an anagram. The *Recueil* caused a quarrel with Ronsard, about which much speculation has been wasted, and which still remains obscure. It seems that Ronsard had invented a new form of the ode, which he allowed Du Bellay to see in manuscript. Ronsard's book was delayed in publication, and Du Bellay's odes, written after his metrical pattern, appeared first. Ronsard's natural and passing vexation has been exaggerated into a law-suit; but the friends were soon on the old affectionate footing. In *L'Olive* Du Bellay was the first French writer to use the sonnet with fluency. After he had translated two books of the Æneid, which appeared in 1552, the yearning he had always felt to visit Italy was appeased by his being sent to Rome in 1550 as secretary to his influential relative, Cardinal du Bellay, and he remained in that city four years and a half. At first, however, he was miserable enough. Everything around him was displeasing to him and jarred on his refined and sometimes sickly nerves. At last he fell violently in love with a lady, whose real name was Faustine, but whom he celebrates under the poetical title of Columba and Columbelle. In his Latin poems this sincere and absorbing passion burns like a clear flame, more veiled though no less burning in his French *Regrets*. Before he won her she was shut up from his sight by her old and jealous husband. Frenzied with grief and desire, burning with fever, exhausted with watching and physical suffering,—for his health was still very delicate,—Du Bellay walked day and night to and fro before the house. At last, mysteriously enough, she is given to him; and the Latin poems end in rapturous delight. At this point, however, and possibly for this reason, he was hurried back to Paris, where he became canon of Nötre Dame in June 1555. He returned by Venice, the Grisons, and Geneva, and was received by his friends in France with transport. He set himself to literary labour of various kinds, publishing his Latin poems and his French sonnets called *Les Antiquitez de Rome*, in 1558, and his greatest lyrical work, the *Regrets*, in 1559. In the latter year, however, a culumny deprived him of the protection of the cardinal, and threw him into the deepest distress and embarrassment. The nature of this charge is not known, but it must have quickly passed away, for later on in that year we find him preparing a new volume of poems, *Les Jeux Rustiques*, for the press, and nominated archbishop of Bordeaux. He did not live to enjoy this distinction, for on the 1st of January 1560, he died of apoplexy, and was buried in Nötre-Dame de Paris. Like Ronsard he was very deaf.

His collected works did not appear until 1568. The early death of the French Ovid, as he has been called, was a serious loss to European literature, for Joachim du Bellay was at the height of his power, and still rapidly advancing. His poems have a force, an occasional sublimity, and a direct pathos for which we look in vain among his contemporaries; and none but Ronsard excelled him in facility and grace. His most famous poem, *Un Vanneur de Blé aux Vents*, one of the loveliest lyrics of the age, was written shortly before his death, and appeared in the *Jeux Rustiques* in 1560; it is nominally a paraphrase from the Latin of Naugerius. The standard edition of the French works of Joachim du Bellay is that published in 2 vols., by Lemerre in 1866, and edited by Ch. Marty-Laveaux. Spenser translated sixty of Du Bellay's Roman sonnets into English, and published them in 1591. A very delicate essay on the poet will be found in Mr W. H. Pater's *Studies in the History of the Renaissance*, 1873.

BELLE-ISLE-EN-MER, an island on the W. coast of France, belonging to the department of Morbihan. It is about 10 miles in length by 4 or 5 in breadth, and is divided into the four communes of Palais, Bangor, Porte Philippe, and Locmaria. The inhabitants are principally engaged in agriculture and the fisheries, and in the preservation of sardines, anchovies, &c. The breed of draught horses in the island is highly prized. The chief town, Palais, is a military town of the first class, and possesses a port which is accessible to vessels of 300 tons. It is evident that Belle-isle must have been inhabited from a very early period, as it possesses several rude stone monuments of the class usually called Druidic. The Roman name of the island seems to have been Vindilis, which in the Middle Ages became corrupted to Guedel. In 1572 the monks of the abbey of St Croix at Quimperlé sold the island to the Retz family, in whose favour it was raised to a marquisate in the following year. From 1761 to 1763 it was held by English troops. Under Napoleon I. the refortification of the island was undertaken, but it was never completed. In the state prison of Nouvelle Force at Palais political prisoners have been at various times confined. The population of Palais in 1870 was 3375, of the island rather under 10,000. The lighthouse is situated in 47° 18′ 43″ N. lat. and 3° 4′ 43″ W. long.

BELLEAU, Remy, French poet of the Renaissance, and member of the Pleiad, was born at Nogent-le-Rotrou in 1528. He became attached to the Elbœufs, and accompanied the head of the family in the expedition against Naples in 1557, where he did good military service. On his return he was made tutor to the young Charles, marquis d'Elbœuf, who, under Belleau's training, became a great patron of the muses. Belleau was extremely learned in the newly-discovered literature of Greece and Rome, and joined the young group of poets with ardour. In 1556 he published the first translation of Anacreon which appeared in French, but this work had no great success. He first became famous through his commentaries to Ronsard's *Amours* in 1560, notes which evinced delicate taste and prodigious learning. Like Ronsard and Du Bellay, he was extremely deaf. His days passed peacefully in the midst of his books and friends, and terminated on the 6th of March 1577. His body was buried in the nave of the Grands Augustins de Paris, and was borne to the tomb on the pious shoulders of four illustrious poets, Ronsard, J. A. de Baif, Philippes Desportes, and Amadis Jamyn. His greatest work is *La Bergerie*, a pastoral in prose and verse, written in a faded rococo style, in imitation of Sannazaro, but containing, as Sainte-Beuve says, some adorable things. Belleau was the French Herrick, full of picturesqueness, warmth, and colour, but of doubtful taste and wanting in passion. His skies drop flowers and all his air is perfumed, but one becomes weary at last of this excess of sweetness. Extremely popular in his own age, he became undeservedly forgotten in the next. Regnier said, "Belleau ne parle pas comme on parle à la ville;" and his lyrical beauty was lost on the trim 17th century. His complete works were collected in 1578, and contain, besides the Anacreon, *La Bergerie*, and miscellaneous odes and sonnets, a comedy entitled *La Reconnue*, in short rhymed lines, which is not without humour and life. This was one of the earliest productions of the French stage. The best edition of Remy Belleau is that published by Jannet in 1867, in 3 vols., and edited by A. Gouverneur.

BELLENDEN, John, a Scotch poet, and the translator of Boece's *History*, was born about the beginning of the 16th century, probably in East Lothian. He appears to have been educated, first at the University of St Andrews and then at that of Paris, where he took the degree of doctor. From his own statement we learn that he had been in the service of James V. from the king's earliest years, and that the post he held was clerk of accounts. It was at the request of James that he undertook his translations of Boece and of Livy. As a reward for his labours he was appointed to the archdeaconry of Moray, and was also made a canon of Ross. Bellenden, who was a strenuous opponent of the Reformation, is said to have died at Rome in 1550. His translation of Boece, which is a remarkable specimen of Scottish prose, distinguished by its freedom and vigour of expression, appears to have been first published in 1536. The best edition is that superintended by Mr Maitland, 2 vols. 4to, Edin., 1821. The same gentleman edited for the first time (Edin., 1822) Bellenden's translation of Livy, which extends only to the first five books. The few poetical remains exhibit considerable taste and skill in versification.

BELLENDEN, William, a distinguished classical scholar, who flourished during the early part of the 17th century, is said to have been a professor at the University of Paris. Nothing is known with certainty of his life, except that he held the office, probably a sinecure, of Master of Requests. The first of the works by which he is known was published in 1608, with the title *Ciceronis Princeps, Rationes et Consilia bene gerendi firmandique Imperii, ex iis repetita quæ ex Ciceronis defluxere fontibus in libros* xvi. *de Statu Rerum Romanarum, qui nondum lucem acceperunt.* It is a laborious compilation of all Cicero's remarks on the origin and principles of regal government, digested and systematically arranged. In 1612 there appeared a similar work, devoted to the consideration of consular authority and the Roman senate, *Ciceronis Consul, Senator, Senatusque Romanus.* His third work, *De Statu Prisci Orbis*, 1615, is a good outline of general history. All three works were combined in a single large volume, entitled *De Statu Libri Tres*, 1615, which was first brought into due notice by Dr Parr, who, in 1787, published an edition with a preface, famous for the elegance of its Latinity and the vehemence of its politics. The greatest of Bellenden's works is the extensive treatise published posthumously in 1633, *Gulielmi Bellendeni Scoti, Magistri supplicum Libellorum Augusti Regis Magnæ Britanniæ, de tribus Luminibus Romanorum libri sexdecim.* The book is unfinished, and treats only of the first luminary, Cicero; the others intended were apparently Seneca and Pliny, probably the younger. It contains a most elaborate history of Rome and its institutions, drawn from Cicero, and thus forms a well-arranged storehouse of all the historical notices contained in that voluminous author. It has been suspected that Middleton was indebted for much of the information contained in his *Life of Cicero* to Bellenden's little known work.

BELLEROPHON (Βελλεροφῶν or Βελλεροφόντης), in *Greek Legend*, a local hero of Corinth, but partly also connected with, and partly similar to, Perseus, the local hero of the neighbouring Argos, the points of likeness being such as to suggest that they had originally been one and the same hero, while the difference in their exploits might result from the rivalry of the two towns. Both are connected with the sun-god Helios and with the sea-god Poseidon, the symbol of the union being the winged horse Pegasus. Bellerophon was a son of Glaucus of Corinth, who is spoken of as a son of Poseidon, and in some way himself a marine deity. To account for the name, *i.e.*, "slayer of Belleros," an otherwise unknown hero of this name was invented. But it is by no means certain that "Belleros" is a personal name; it may mean nothing more than "monster."

The first act of Bellerophon was to capture the horse Pegasus, when it alighted on the Acrocorinth to drink at the fountain of Peirene, with a bridle which he found by his side on awaking from sleep beside the altar of Athene, where he had laid himself down on the advice of a seer Polyidus. The goddess had appeared to him in a dream, reached him a golden bridle, and told him to sacrifice a white bull to his father Poseidon. The next incident occurs in Tiryns, at the court of Prœtus, whose wife, Sthenebœa (or Anteia, as Homer calls her), failing to seduce Bellerophon, charges him with an attempt on her virtue (*Iliad*, vi. 150–211). Prœtus now sends him to Iobates, his wife's father, the king of Lycia, with a letter or sealed tablet, in which were instructions, apparently by means of signs, to take the life of the bearer. Arriving in Lycia, he was received as a guest and entertained for nine days. On the tenth, being asked the object of his visit, he handed the letter to the king, whose first plan for complying with it was to send him to slay the Chimæra, a monster which was devastating the country. Its forepart was that of a lion, its hindpart that of a serpent; a goat's head sprang from its back, and fire was vomited from its mouth. Bellerophon, mounted on Pegasus, kept up in the air out of the way of the Chimæra, but yet near enough to kill it with his spear, or as he is at other times represented, with his sword or with a bow. He was next ordered out against the Solymi, a hostile tribe, and afterwards against the Amazons, from both of which expeditions he not only returned victorious, but also on his way back slew an ambush of chosen warriors whom Iobates had placed to intercept him. His divine origin was now proved; the king gave him his daughter in marriage; and the Lycians presented him with a large and fertile estate on which he lived, and reached the pinnacle of happiness, surrounded by two sons, Isander and Hippolochus, and one daughter, Laodamia. But, as in the case of Hercules, the gods now punished him with frenzy. His son Isander fell in battle; his daughter was slain by Artemis; and he himself wandered in the "plain of madness" (πεδίον Ἀλήιον). The cause of his misfortune, Pindar (*Isthm.*, vii. 44; *Olymp.*, xiii. 91) says, was his ambitious attempt to mount to the heavens on Pegasus.

The early relations between Lycia and Argolis are attested by the tradition that the walls of Mycenæ had been built by Cyclopes from Lycia. In both districts the worship of the sun-god had exercised great influence in very early times. The two most frequent representations of Bellerophon in ancient art are (1) when he slays the Chimæra, and (2) when he departs from Argos with the letter. Among the first is to be noted a terra-cotta relief from Melos in the British Museum, where also, on a vase of black ware, is what seems to be a representation of his escape from Sthenebœa.

BELLEVILLE, a city of the United States of America, capital of the county of St Clair in Illinois, situated about 14 miles S.E. of St Louis on a rising ground, in the midst of a fertile district. It is a thriving commercial and manufacturing city, well supplied with water, and in the immediate neighbourhood of coal deposits. Its industrial establishments comprise breweries, flour-mills, distilleries, foundries, and a woollen factory, and it possesses a court-house, banks, a high school, a convent for the education of young ladies, and various other institutions. There is a sufficient number of German inhabitants to maintain one daily and two weekly papers in their native language. Population in 1870, 8146.

BELLEY, the capital of an arrondissement in the department of Ain, France, is situated near the Rhone, 39 miles east of Lyons. It is the seat of a bishopric founded in 412, and contains an episcopal palace, a cathedral, an ecclesiastical school, a museum, and a public library. The principal industries are the weaving of cotton goods and the culture of the silk-worm. Important fairs are held for the sale of cattle and horses. In the vicinity are found the best lithographic stones in France. Belley is a place of considerable antiquity, and preserves the remains of a Roman temple. It was the capital of the district of Bugey, which maintained its separate constitution down to the Revolution. The neighbourhood is remarkable for its objects of interest both natural and historical, such as the cascades of Glandieux, the intermitting fountain of Grouin, and the Carthusian abbeys at Arvières and Portes. Population in 1872, 3902.

BELLINI, the name of an honourable Venetian family. Three members of this family fill a great place in the history of the Venetian school of painting in the 15th century and at the beginning of the 16th. In their hands the art of Venice was developed from a condition more primitive and archaic than that of any other school in Italy, and advanced to the final perfection of Giorgione and of Titian. The first distinguished member of the family was—

1. Jacopo Bellini. When Gentile da Fabriano, one of the most refined and accomplished of the religious painters of the Umbrian Apennines, came to practise at Venice, where art was backward, several young men of the city took service under him as pupils. Among these were Giovanni and Antonio of Murano, and Jacopo Bellini. The Umbrian master left Venice for Florence in 1422, and the two brothers of Murano stayed behind and presently founded a school of their own. (See Vivarini.) But Jacopo Bellini followed his teacher to Florence in the capacity of *famulus*. It was the time when a new spirit had just broken out in Florentine art, and when the leaders of that school—Ghiberti and Donatello, Andrea del Castagno, Paolo Uccello, Masaccio—had made immense progress in many ways at once,—in the sciences of anatomy and perspective, in classical grace and style, in the truth and sincerity of nature,—so that from them the young Venetian found much more to learn than even from his Umbrian teacher as to the possible perfections of the art. The little evidence left us proves that he made good use of his opportunities. But his works are as rare as the events of his life, after his service in Florence with Gentile da Fabriano, are uncertain. That service presently got him into trouble. The Umbrian, as a stranger coming to paint in Florence, was jealously looked on. One day a group of young Florentines took to throwing stones into his shop, and the Venetian pupil ran out and put them to flight with his fists. Thinking this might be turned against him, he went and took service on board the galleys of the Florentine state; but, returning after a year, he found he had in his absence been tried for assault and condemned in a heavy fine. He was arrested and put in prison, but the matter was afterwards compromised upon a public act of penance to which Jacopo submitted. Whether he accompanied his master to Rome in 1426 we cannot tell, but there is evidence to show that he was practising on his own account in Venice in 1430, and probably as soon as 1427. Neither can we fix the date of his marriage; but it was probably about the time of his return to his native state, for we know that he had grandchildren before 1458. The remainder of his life was spent between Venice, Verona, and Padua. At Venice, besides other work, he painted a great series from the lives of Christ and the Virgin in the church of St John the Evangelist. This has entirely

perished. In the cathedral of Verona there was, until it was destroyed by the barbarism of the 18th century, an important Crucifixion from his hand. In the archbishop's palace of the same city another Crucifixion still remains, but greatly injured. At Padua Jacopo appears to have lived several years, and to have founded there a school which became the rival of the school of Squarcione. There his sons, Gentile and Giovanni, grew up; there his daughter Niccolosia found a husband in Andrea Mantegna, the most famous of the scholars of Squarcione. (See MANTEGNA.) In Jacopo Bellini the Venetian school had not yet found its special and characteristic manner. But he holds a position of great importance, as having been the first to fertilize Venetian soil with the science and genius of Florence. From no extant pictures of his can his manner be judged so well as from the book of his sketches, which has become the property of the British Museum. This, in spite of fading and decay, is a unique and invaluable possession, containing a vast number of original studies tinted or drawn with pen or ink, and including compositions from Scripture and the lives of the saints, from classical fable, and from natural history in surprising variety.

2. GENTILE BELLINI was the elder of the two sons of Jacopo. To the precise date of his birth we have no clue. Both he and his brother Giovanni served together under their father Jacopo as his pupils as long as he lived. After his death each of them practised his art independently in their native city; but a warm and unbroken affection is recorded to have always subsisted between the brothers. In 1464 Gentile was commissioned to paint the doors of the great organ in St Mark's with figures of the four saints—Mark, Jerome, Theodore, and Francis. The next year he painted for the church of Sta Maria dell' Orto a picture of the apotheosis of Lorenzo Giustiniani, patriarch of Venice. From 1465 until 1474 we cannot trace his occupations with precision, though there are several extant works that can be assigned to the interval. On the 21st of September 1474, he was appointed to restore and renew the existing painted decorations in the hall of the Great Council in the Ducal Palace. These were in part frescoes, the work of his father's master, Gentile da Fabriano. Some of them Gentile Bellini restored, and some were so ruined that he had to destroy them and put in their place new work of his own. The practice of painting in oil upon canvas had lately been brought to Venice by Antonello of Messina. The new medium, besides yielding richer effects, resisted damp and salt better than the old; and all the painters of Venice were eagerly learning its use. Gentile adopted it in the hall of the Great Council. In 1479 the Sultan Mahomet sent word to the Signoria of Venice that he desired the services at Constantinople of a good painter of their state, at the same time inviting the doge to the wedding of his son. The doge declined to go, but the Signoria chose Gentile Bellini to be sent with two assistants at the expense of the state and to paint for the Turk, first electing his younger brother Giovanni to fill his place in the works at the Ducal Palace until he should return. He was admirably received, and painted the portraits of the sultan and many of his officers, besides that picture of the reception of a Venetian embassy by the grand vizier which is now at the Louvre (No. 68). It is a well-known and doubtful story how the sultan alleged that a picture of Gentile's showed an imperfect knowledge of the appearance of the muscles of the neck after decapitation, and to convince the painter had a slave decapitated in his presence, and how this made Gentile uncomfortable and anxious to get away. He returned at the end of 1480, bringing gifts and honour; and from that time he and Giovanni were engaged together for the state on the decoration of the great hall. Gentile painted there four great subjects from the story of Barbarossa, which unhappily perished in the fire of 1577. It is recorded that in 1486 the young Titian entered his workship as a pupil. Three of the most important of his works date from the last five or six years of the century, and were done for the school of St John the Evangelist at Venice. They represent the cure of a sick Venetian by a relic of the cross, the procession in honour of the same relic in the piazza of St Mark, and the miracle of the recovery of the relic from the Grand Canal (Academy of Venice, Nos. 543, 555, 529). In 1506 Gentile was so busy as to write that he could not accept a commission proposed by Francesco, marquis of Mantua. The next winter he fell sick, and made his will, bequeathing his father's sketch-book above described to his brother John, on condition that the brother should finish the picture of the Sermon of St Mark which the sick man had then on hand. He died on the 23d of February 1507. It is by his science and spirit in the treatment of animated and dignified processional groups, with many figures and architecture of masterly perspective, that we chiefly know Gentile Bellini. He is a workman of infinite precision, and a fine colourist, though his manner has some of the hardness of the earlier times. To conduct the school of Venice to its final liberty and splendour was the work of his younger brother, the great

3. GIOVANNI BELLINI. His birth it is no less impossible to fix with accuracy than that of his brother. His earliest work, done at Padua, shows strongly the stern influence of his brother-in-law Andrea Mantegna. The National Gallery has a Christ on the Mount, painted by Giovanni, probably about 1455, and apparently in direct competition with a picture of the same subject by Mantegna himself, similarly conceived, which belongs to the Baring Gallery. The characteristics of the style formed at Padua by Mantegna and Giovanni Bellini, and maintained by the former all his life, are a great intensity and vehemence of expression, an iron severity and unmatched firmness and strength of draughtsmanship; a tendency, in draperies, to imitate the qualities of sculpture; a love of the difficulties of perspective; a leaning towards the antique, which these masters learned to transform and reanimate with a more passionate energy and an austerer strength of their own. Of the two, Bellini is always the more reserved and simple, the more inclined to work from nature and the less from the antique, and he has the richer choice in colour; but there are works in which they are indistinguishable. The period when Bellini painted in this first manner and in *tempera* may be roughly fixed (though there is often great uncertainty as to the dates of his pieces, and though at all times he seems occasionally to have recurred to his early practice) between 1455 and 1472. It is probable that the famous picture of the Circumcision now at Castle Howard, which was repeated more than once by the master himself, and many times over by his pupils and assistants, was painted before this date. The altar pieces on a great scale, which are the noblest monument of his middle period, were certainly painted after it. Of these the chief were the Virgin and Saints, in a chapel of the church of Saints Giovanni and Paolo at Venice, which perished along with Titian's Peter Martyr in the fatal fire of 1867; a great Coronation of the Virgin, in the church of St Dominic at Pesaro; a Transfiguration now in the museum of Naples; a Virgin and Saints, painted for the church of S. Giobbe, now in the Academy at Venice (No. 36). These, and the multitude of Madonnas and other devotional pictures painted by Giovanni Bellini during the thirty years following his change of manner and adoption of the oil medium, are among the noblest products of the religious art of the world. They stand alone in their union of

splendour with solemnity; they have the manful energy of Mantegna without his harshness, and the richness of Giorgione without his luxury. Succeeding pictures show an increase of this richness, and a character more nearly tender. An altar piece, painted for the church of San Zaccaria, seems to indicate a transition, and that the venerable master is acquiring all the softer splendour and keeping pace with Giorgione and Titian, the young pupils of the school. Nay, at the very close of his career, Bellini left the old devotional cycle in which he had produced works so moving and august, and painted for Alphonso of Ferrara a mythology in the most gorgeous manner of the ripe Venetian school. This is the Feast of the Gods, now at Alnwick Castle, a picture to which Titian set the finishing touches, and to which the companion, by Titian himself, is now at Madrid. Bellini died on the 29th of November 1516, full of years and honours. We have seen that he was associated with his brother in the decoration of the Great Hall of the Council in 1479. In 1483 he was appointed Pittore del Dominio, and exempted from the charges of his guild. All the painters of the state at one time or another were associated with him or passed through his school. Among the most distinguished of his scholars and assistants who will not need separate mention, we may name Marco Basaiti and Vincenzo Catena, many of whose works pass for their master's. He was the honoured associate of statesmen and men of letters. In 1506, when Albert Durer visited Venice, where he was subject to some annoyances, he found the noble old man not only the most courteous of the Venetian artists in his reception of a stranger, but the best in his profession ("der best im gemell").

Many pictures in various galleries pass as portraits of one or other of the Bellini. But of those that are styled likenesses of Giovanni, none can be proved authentic, while the only certain portrait of Gentile is a medal by Camelio. (Vasari, ed. Lemonnier, vol. v pp. 1–28; Sansovino, *Ven. descr.*, 125, *seq.*; Ridolfi, i. 90–99; Crowe and Cavalcaselle, *History of Painting in North Italy*, vol. i. pp. 100–193.) (S. C.)

BELLINI, LORENZO, physician and anatomist, was born at Florence in 1643. After completing his studies in general literature he went to Pisa, where, assisted by the generosity of the grand duke Ferdinand II., he studied under two of the most learned men of that age, Oliva and Borelli, the former of whom instructed him in natural philosophy and the latter in mechanics. He likewise studied medicine under Redi, and mathematics under Marchetti. At the early age of twenty he was chosen professor of philosophy at Pisa, but did not long continue in this office; for he had acquired such a reputation for skill in anatomy, that the grand duke procured him a professorship in that science, and was himself a frequent auditor at his lectures. After a long residence in Pisa, he was invited to Florence and appointed physician to the grand duke Cosmo. He was also made senior consulting physician to Pope Clement XI. Bellini died in 1703, in the sixtieth year of his age. His works were published in a collected form in 1708 (2 vols. 4to), and reprinted in 1732.

BELLINI, VINCENZO, one of the most celebrated operatic composers of the modern Italian school, was born at Catania in Sicily, November 3, 1802. He was descended from a family of musicians, both his father and grandfather having been composers of some reputation. After having received his preparatory musical education at home, he entered the conservatoire of Naples, where he studied singing and composition under Tritto and Zingarelli. He soon began to write pieces for various instruments, as well as a cantata and several masses and other sacred compositions. His first opera, *Adelson e Savina*, was performed in 1824 at a small theatre of Naples; his second dramatic work, *Bianca e Fernando*, saw the light two years later at the San Carlo theatre of the same city, and made his name known in Italy. His next work, *Il Pirata*, was written for the celebrated Scala theatre in Milan, to words by Felice Romano, with whom Bellini formed a union of friendship to be severed only by his death. The splendid rendering of the music by Tamburini, Rubini, and other great Italian singers, contributed greatly to the success of the work, which at once established the European reputation of its composer. Almost every year of the short remainder of his life witnessed the production of a new operatic work, each of which was received with rapture by the audiences of France, Italy, Germany, and England, and some of which retain their place on the stage up to the present day. We mention the names and dates of four of Bellini's operas familiar to most lovers of modern Italian music, viz.:—*I Montecchi e Capuleti* (1829), in which the part of Romeo has been a favourite with all the great contraltos of the last seventy years; *La Sonnambula* (1831); *Norma*, Bellini's best and most popular creation (1832), and *I Puritani* (1834), written for the Italian opera in Paris, and to some extent under the influence of French music. In 1833 Bellini had left his country to accompany to England the great singer Pasta, who had created the part of his *Sonnambula*. In 1834 he accepted an invitation to write an opera for the national Grand Opera in Paris. While he was carefully studying the French language and the cadence of French verse for the purpose, he was seized with a sudden illness and died at his villa in Puteaux near Paris, September 21, 1835. This unexpected interruption of a career so brilliant sheds, as it were, a gloom of sadness over the whole of Bellini's life, a sadness which, moreover, was foreshadowed by the character of the works. His operatic creations are throughout replete with a spirit of gentle melancholy, frequently monotonous and almost always undramatic, but at the same time irresistibly sweet, and almost disarming the stern demands of higher criticism which otherwise would be compelled to reprove the absence of both dramatic vigour and musical depth. To the feature just mentioned, combined with a rich flow of *cantilena*, Bellini's operas owe their popularity, and will owe it as long as the audiences of our large theatres are willing to tolerate outrages on rhyme and reason if sung by a beautiful voice to a pleasing tune. In so far, however, as the defects of Bellini's style are characteristic of the school to which he belongs, they fall to be considered in a general treatment of the whole subject. See MUSIC.

BELLINZONA, or BELLENZ, one of the three towns which are the capital in turn of the Swiss canton of Tessin or Ticino. It is built on two hills, one on each side of the Ticino at the entrance of the Riviera valley, and is so situated as completely to bar the passage by that route between Italy and Germany. Its fortifications, which were of great strength during the Middle Ages, have been partially restored. There are three castles, the Castello Grande, Corbario, and Di Mezzo, which belonged to the three cantons of Uri, Unterwalden, and Schwyz respectively; the first of these is now used as an armoury and prison. The abbey church is a fine building of the 16th century, and contains some paintings of value. The Augustinian convent is now used as a Government house. The inundations of the river are prevented from injuring the town by a large dyke, built by the French in the reign of Francis I. A considerable transit trade is carried on with Italy, and there is a famous manufacture of *acqua di cedro* from the blossom and rind of the orange. Bellinzona was in existence at least as early as 1242, when it was conquered by Otto Visconti. It was long an object of contest between the Swiss and the

Milanese; in the 15th century it was the scene of a famous battle, in which the Swiss were defeated; and it finally passed into the hands of the three cantons of Uri, Unterwalden, and Schwyz after the battle of Marignano in 1515. Population in 1870, 2051.

BELLMAN, KARL MIKAEL, the greatest lyrical poet of Sweden, was born at Stockholm on the 4th of February 1740. His father, who held a responsible official position, was descended from a family that had already distinguished itself in the fine arts; his mother, a gifted and beautiful woman, early instructed him in the elements of poetry and music. When quite a child he suddenly developed his extraordinary gift of improvising verse, during the delirium of a severe illness, weaving wild thoughts together lyrically, and singing airs of his own composition. From this time he gave himself up to the poetic art, and received great encouragement from the various eminent men who met round his father's table, among whom was Dalin, the favourite poet of the day. As early as 1757 he published a book of verse, a translation of Schweidnitz's *Evangelical Thoughts of Death*, and for the next few years wrote a great quantity of poems, imitative for the most part of Dalin. In 1760 appeared his first characteristic work, *The Moon*, a satirical poem, which was revised and edited by Dalin. But the great work of his life occupied him from 1765 to 1780, and consists of the collections of dithyrambic odes known as *Fredman's Epistles* and *Fredman's Songs*. These were not printed until 1790. The mode of their composition was extraordinary. No poetry can possibly smell less of the lamp than Bellman's. He was accustomed, when in the presence of none but confidential friends, to announce that the god was about to visit him. He would shut his eyes, take his zither, and begin to improvize a long Bacchic ode in praise of love or wine, and sing it to a melody of his own invention. The genuineness of these extremely singular fits of inspiration could not be doubted. The poems which Bellman wrote in the usual way were tame, poor, and without character. The *Fredman's Epistles* glow with colour, ring with fierce and mysterious melody, and bear the clear impress of individual genius. These torrents of rhymes are not without their method; wild as they seem, they all conform to the rules of style, and among those that have been preserved there are few that are not perfect in form. The odes of Bellman breathe a passionate love of life; he is amorous of existence, and keen after pleasure, but under all the frenzy there is a pathos, a yearning that is sadder than tears. The most dissimilar elements are united in his poems; in a bacchanal hymn the music will often fade away into a sad elegiac vein, and the rare picturesqueness of his idyllic pictures is warmed into rich colour by the geniality of his humour. He is sometimes frantic, sometimes gross, but always ready, at his wildest moment, to melt into reverie. A great Swedish critic has remarked that the voluptuous joviality of Bellman is, after all, only "sorrow clad in rose-colour," and this underlying pathos gives his poems their undying charm. His later works, *The Temple of Bacchus*, a journal called *What you Will*, a religious anthology entitled *Zion's Holiday*, and a translation of Gellert's *Fables*, are comparatively unimportant. He died on the 11th of February 1795. Several statues exist of Bellman. One represents him naked, crowned with ivy, and striking the guitar; the best is the splendid colossal bust by Byström, which adorns the public gardens of Stockholm, which was erected by the Swedish Academy in 1829. Bellman had a grand manner, a fine voice, and great gifts of mimicry, and was a favourite companion of King Gustavus III. The best edition of his works is one lately published at Stockholm, edited by J. G. Carlén.

BELLONA, in *Roman Mythology*, the goddess of war, corresponding to the Greek Enyo, and called now the sister or daughter of Mars, now his charioteer or his nurse. Her worship appears to have been promoted in Rome chiefly by the family of the Claudii, whose Sabine origin, together with their use of the name of "Nero," has suggested an identification of Bellona with the Sabine war goddess Nerio. Her temple at Rome, founded by Appius Claudius Cæcus, 296 B.C., stood in the Campus Martius, near the Flaminian Circus, and outside the gates of the city. It was there that the senate met to discuss the claims of a general to a triumph, and to receive ambassadors from foreign states. In front of it was the *columna bellica* where the ceremony of declaring war was performed. From this native Italian goddess is to be distinguished the Asiatic Bellona, whose worship was introduced into Rome from Comana, in Cappadocia, apparently by Sulla, to whom she had appeared, urging him to march to Rome and bathe in the blood of his enemies. For her a new temple was built, and a college of priests (Bellonarii) instituted to conduct her fanatical rites, the prominent feature of which was to lacerate themselves and sprinkle the blood on the spectators. To make the scene more grim they wore black dresses from head to foot.

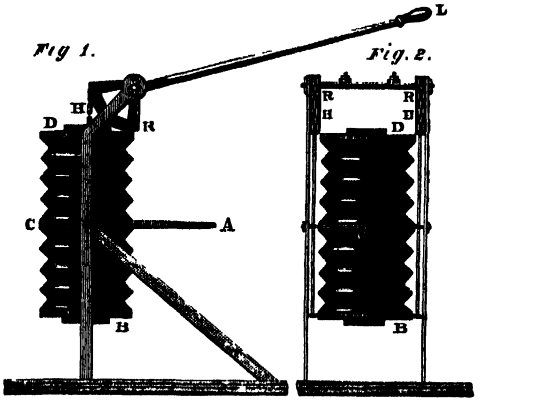
BELLOT, JOSEPH RENÉ, one of the heroes and victims of Arctic exploration, was born at Paris, March 18, 1826. At the age of fifteen he entered the Naval School, in which he studied two years, and earned a high reputation. He distinguished himself in the French expedition of 1845 against Tamatave in Madagascar; and although he was not yet twenty he received the cross of the Legion of Honour at the close of that year. He was afterwards attached to the staff of the station, was promoted to the rank of *Enseigne de Vaisseau* in November 1847, and in 1851 obtained permission to join the English expedition then preparing to go out, under the command of Captain Kennedy, in search of Sir John Franklin. On this occasion he displayed great courage, presence of mind, and self-devotion, rendered important services, and made the discovery of the strait, which bears his name, between Boothia Felix and Somerset Land. Early in 1852 he was promoted lieutenant. In the same year he accompanied, as a volunteer, the expedition sent out by the English Government under Captain Inglefield on the same quest. His intelligence, his devotion to duty, and his courage won him the esteem and admiration of all with whom he was associated. While making a perilous journey with two comrades across the ice, for the purpose of communicating with Captain Inglefield, he was overtaken by a storm, August 21, and being blown into an opening between the broken masses of ice was seen no more. A pension was granted to his family by the Emperor Napoleon III., and an obelisk was erected to his memory in front of Greenwich Hospital.

BELLOWS AND BLOWING-MACHINES are machines for producing a current of air, chiefly in order to assist the combustion of a fire.

The common bellows now in use probably represents one of the oldest contrivances for this purpose. It consists of two flat boards, of oval or triangular shape, connected round their edges by a piece of leather so as to form an air chamber. The leather is kept from collapsing, on separation of the boards, by two or more hoops, which act like the ribs in animals. The lower board has a hole in its centre covered inside by a leather flap or valve opening inwards; it has also fastened to it a metal pipe or nozzle, of smaller aperture than the valve. On raising the upper board, the air from without lifts the valve and enters the cavity; then on pressing down the top board, this air is compressed, shuts the valve, and is driven through the pipe with a velocity corresponding to the pressure.

The blast here is, of course, not continuous, but in puffs,—a certain interval being needed for refilling the bellows after each discharge. This drawback was remedied by the invention of double bellows. To understand their action, it is only necessary to conceive an additional board with valve, like the lower board of the single bellows, attached by leather under this lower board. Thus two similar cavities are obtained, separated by the lower board of what was the single bellows. The lowest board is held down by a weight, and another weight presses the top board. When the lowest board is raised it forces air into the upper cavity, and the valve of the middle board prevents return of this air. The lowest board being then depressed, air enters the lower cavity from without, and this in its turn is next forced into the upper cavity. The weighted top board is meanwhile continuously pressing the air of the upper cavity through the nozzle. While the blast thus obtained is continuous, it is not wholly free from irregularities.

The common smiths' bellows, made on the principle just indicated, are generally of circular form, as shown in figs. 1 and 2. A is the blast pipe, B the movable lowest board, C the fixed middle board (into which the pipe is inserted), and D the movable upper board pressed by a weight. The lowest board is moved by means of the lever L and the chain H working on the roller R. The weight required to produce a certain force of blast is easily determined, if the diameter of the bellows be 1 foot, the area will be 113·19 inches, and the upper board will require a weight of 56·5 ℔ for a blast equivalent to a pressure of ½ ℔ on the square inch, or a velocity of 207 feet per second, which is well suited for a smith's forge. By a simple arrangement for altering the diameter of the pipe the force of the blast may be varied.



FIGS. 1 and 2.—Common Smiths' Bellows.

It may be noted that in some parts of the Continent a simple form of bellows is made of two wooden boxes, each open on one side, and the one just fitting into the other. The open sides being opposed to each other, the upper enclosing box is made to move up and down over the other, with which it is jointed at one part, and which is provided with a nozzle, and a valve opening inwards. The change of capacity produces a blast. There is considerable loss of air, however, from the boxes not exactly fitting.

The blowing-machines now almost exclusively used for blast furnaces are of the cylinder and piston type (which is the principle adopted, it may be remarked, in a small hand bellows used by the Chinese). At first the blowing cylinders were single-acting, that is to say, they had the power of propelling a blast only when the piston was moving in one direction. With two or more of these blowing cylinders attached to one crank-shaft, worked by a water-wheel, a tolerably steady pressure of air was obtained. But in these and other respects considerable progress has been realized.

The cylinder-engines of the present day (which are generally driven by steam) may be classed in two chief systems, according as the cylinder is placed horizontally or vertically. In the former case the steam and blast cylinders are usually in one line, the same rod carrying the pistons of both, and being guided on both sides, while a fly-wheel is employed as regulator. In the vertical systems the steam and blowing cylinders are sometimes similarly connected, but, in the larger engines, they are generally placed one at each end of a beam connecting their pistons. The vertical engines have been most popular in England and in some parts of the Continent (as Silesia), but the other type (almost exclusively used in Westphalia and on the Rhine) is now adopted in several English works.

The general action of many of these machines may be illustrated by the large blowing engine at the Dowlais iron-works, erected in 1851. Fig. 3 is a representation of

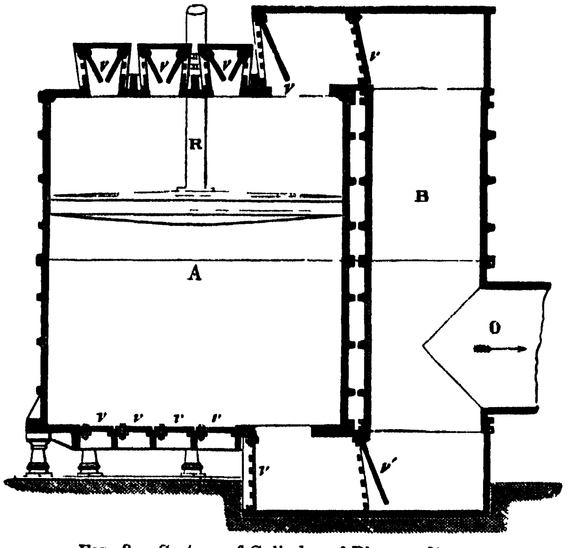


FIG. 3.—Section of Cylinder of Blowing Engine.

its blast cylinder, the piston of which, made air-tight by packing, is moved by the oscillating beam of the engine. The cover of the cylinder, and also its bottom, have several openings, furnished with valves *v*, which open inwards. Other valves *v'*, above and below, open into a lateral chamber B, which is connected by the aperture O to the different tuyeres of the furnaces. Suppose, now, the piston is at the top and begins to be forced down. The air in the upper part of the cylinder becomes more and more rarefied, and the difference of density between it and that of the blast in chamber B, causes the upper valve *v'* to be applied firmly to the metallic surface before which it is hung. The upper valves *v*, on the other hand, will be raised by the external air which enters to compensate the rarefaction. The same motion of the piston compresses the air below it, causing the lower valves *v* (which open inwards) to be firmly closed, while the valve *v'* will be raised and admit the air into chamber B, whence it passes to the furnace. When the piston is raised the reverse takes place; the lower portion of the cylinder receives air from without, and the upper discharges its air through the pipes leading to the furnace. Thus a nearly continuous flow is obtained. To ensure regularity the pipe O is made to communicate with a closed reservoir of wrought iron, where the variations are destroyed by the elasticity of the air itself. The cylinder here figured is 144 inches in diameter, with a stroke of 12 feet, and discharges about

44,000 cubic feet per minute, at a pressure of $3\frac{1}{4}$ lb to the square inch.

Where it is desirable to make small blast engines do the work of large ones, compensating smallness of size with velocity, it becomes necessary that the air valves be moved otherwise than by the simple action of the air itself. The best form of such an arrangement is that devised by Mr Slate, in which there is an annular slide valve placed outside the blast cylinder; it receives its motion from a crank connected with the fly-wheel shaft. Thus, with lap and lead of the valve properly proportioned, a high velocity can be attained, and the tremor and jar that are observable in some of the larger engines are entirely absent. Two such engines working together, with their cranks at right angles, give such a uniform blast that no regulator of any kind is needed. In Fossey's engine, which appeared in the Exhibition of 1862, the slide valves are replaced by discs with radial perforations, which are put in slow rotatory motion by gearing connected with the main shaft.

The blast engines with slide valves, however, have not proved so advantageous in practice as was anticipated, owing to the large amount of friction on the valve surfaces, greater liability to derangement, and the wear and tear resulting from such rapid motion.

As a recent example of engines of the vertical type, with steam and air cylinders in one line (which have now come a good deal into use in the north of England) we may briefly notice the compound cylinder blowing engines at the Lackenby Iron-Works, Middlesborough. These engines were described by Mr Alfred Hill before the Institution of Mechanical Engineers in 1871. Fig. 4 (copied from the drawings by permission of the Institute and of Mr Hill) presents them in vertical section.

They consist of a high pressure non-condensing engine and a low pressure condensing engine, the latter supplied by steam from the former,—this arrangement being adopted for economical reasons. A is the high pressure cylinder (32 inches in diameter) and C the low pressure (80 inches). Both engines have a stroke of 54 inches; and a peculiarity is that they are coupled by cranks placed directly opposite each other instead of, as usual, at right angles,—a light fly-wheel being relied on to carry them over the dead centres. This secures a better balance of the engines, and expansion of the steam in both cylinders in the most advantageous manner; it also obviates the danger of breakages common in the case of right-angle cranks, which probably arises from the tendency to sudden acceleration of one engine over the other at the commencement of each stroke,—full steam pressure being then upon both pistons simultaneously, whilst the resistance of the blast pressure is acting against only one of the blowing pistons. In the blowing cylinders B, the inlet valves in the bottom are circular disc valves of leather, eighteen in number. The inlet valves T on the top of the cylinder are arranged in ten rectangular boxes, having openings in their vertical sides, inside which are hung leather flap valves. The box covers are made hollow, and are carried down between the backs of the leathern flaps (so as to diminish the air-space as much as possible). The outlet valves *o* for air are ten in number, at each end of the cylinders, and are hung against flat gratings, which are fixed round the circumference of the cylinder. Enclosing each cylinder is an air-tight wrought-iron case M, into which the blast is delivered, and a branch at one side (not shown in figure) conveys the blast to the main. The area of the inlet valves is 860 square inches, or about $\frac{1}{6}$th the area of the piston; that of the outlet valves is about $\frac{1}{8}$th. For details of the balanced slide valves of the steam cylinders, the surface condenser D, the circulating pump E, the air-pump F, the feed pumps G, &c., we must refer to Mr Hill's paper.

The capacity of each blowing cylinder is 157 cubic feet; consequently, the total quantity of blast supplied from both

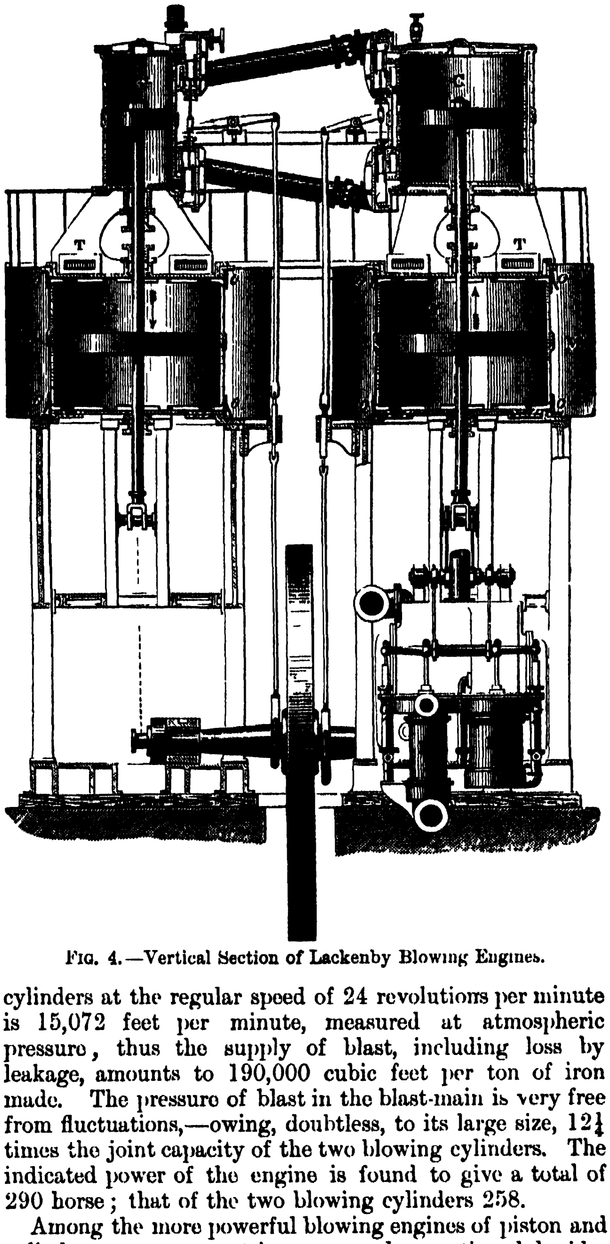

Fig. 4.—Vertical Section of Lackenby Blowing Engines.

cylinders at the regular speed of 24 revolutions per minute is 15,072 feet per minute, measured at atmospheric pressure, thus the supply of blast, including loss by leakage, amounts to 190,000 cubic feet per ton of iron made. The pressure of blast in the blast-main is very free from fluctuations,—owing, doubtless, to its large size, $12\frac{1}{4}$ times the joint capacity of the two blowing cylinders. The indicated power of the engine is found to give a total of 290 horse; that of the two blowing cylinders 258.

Among the more powerful blowing engines of piston and cylinder type at present in use, may be mentioned, besides that at Dowlais referred to above, those of Woolwich dockyard, employed for supplying air to forty forge fires, the Kirkless Hall engines, constructed from Robert Wilson's designs for the Wigan Iron and Coal Company, and the seven engines of Schneider and Co. at Creusot, three of which are horizontal engines of an old type, and the other four direct-acting vertical engines. Descriptions of these will be found in various standard works on metallurgy and engineering. For a description of the large blowing and exhausting engines lately constructed for the new Post-Office in London, see *Engineering*, 20th February 1874.

An ingenious mode of obtaining a blast is adopted in Savoy, Carniola, and in some parts of America; it is the *trompe* or water blowing engine. A flow of a few yards of water is required. From the bottom of a reservoir water is admitted, by removal of a plug from a conical-shaped aperture, into a large vertical wooden pipe, which terminates below in a wind chest. The water, falling

in streamlets, carries down with it air drawn in through sloping holes near the top of the pipe. The wind chest below has an opening for escape of the water, and the air passes out from another part, in a regular stream, by a nozzle pipe. To facilitate separation of the water and the air, it is found advantageous to fix a small platform under the bottom of the pipe, on which the water may impinge in its fall. The tension of the blast is determined by the height from which the water falls; but this height seldom exceeds 27 feet, which gives a pressure of from $1\frac{1}{2}$ to 2 lb to the square inch. While the blast obtained is very equable, there is the serious drawback that the air supplied is always more or less laden with moisture. The action of the *trompe* has been investigated by Mr Rodwell (*Philosophical Mag.*, 1864, 1867).

Another kind of blowing engine, in which water is employed, is that invented by Mr Street; in its simpler form it consists of a barrel-shaped vessel, supported horizontally by the two ends of its axis. The cylinder is divided longitudinally by a plane extending from the middle of the internal surface above (the barrel being in its position of rest) to near the opposite side. Suppose the cylinder partly filled with water and made to turn a little way round on its axis, the air on one side will be compressed by the water, while that on the other will be rarefied. A valve opening outwards from the condensed side admits the air to a cavity from which a nozzle pipe proceeds, while a valve opening inwards on the rarefied side admits external air. With additional and corresponding valves, the process is repeated on the reverse oscillation of the cylinder. Thus by swinging the cylinder from side to side, by a crank and rod connected with the engine, alternate puffs of air are propelled into a regulative air chest of special construction, which then supplies a steady blast.

Fan-blast machines are frequently employed, especially to urge the fire of steam boilers, and in puddling and reheating, and in the cupola furnaces where anthracite is burnt, or coke used for remelting pig-iron in foundries. In one common form the fan consists of four spokes of a rimless wheel, tipped with vanes and made to rotate in a cylindrical chest, in which it has often a slightly eccentric position. There are openings on both sides round the spindle for admission of air, which, sucked in by the centrifugal action of the fan as it quickly rotates, flows towards the vanes, and is driven through an exit pipe attached to another part of the cylinder.

There are numerous varieties of these engines. An American machine, introduced into England a few years ago by Mr Ellis, has found considerable favour. It is represented in section in fig. 5. It consists of an iron cylindrical casing A, open about a fourth part of its circumference (a to b) for admission of air, and an exit pipe B. Inside the casing is another cylinder, placed eccentrically to it, and which always fits close up against the wooden packing C. This cylinder acts as driver for the three fan blades or pistons D, which are capable of passing out and in through longitudinal slits in its circumference. There is a shaft passing through the small cylinder, and concentric with it at the ends, but cranked in the middle part so as to become concentric with the casing. The inner cylinder revolves round the axis of the ends of the shaft, and on the cranked part revolve the fan blades or pistons, driven by the cylinder. The outer extremities of the fan blades follow closely the inside face of the casing. The crank is placed opposite to the point where the inner cylinder touches the inside of the casing, always retaining, it must be remembered, the same position; when passing this point, the blades are wholly withdrawn inside the cylinder, but when passing the opposite point they are thrust out to the fullest extent, and are always working into or out of the inner cylinder as it revolves. The air is thus continually being drawn in at the upper opening, compressed, and delivered by the lower one.

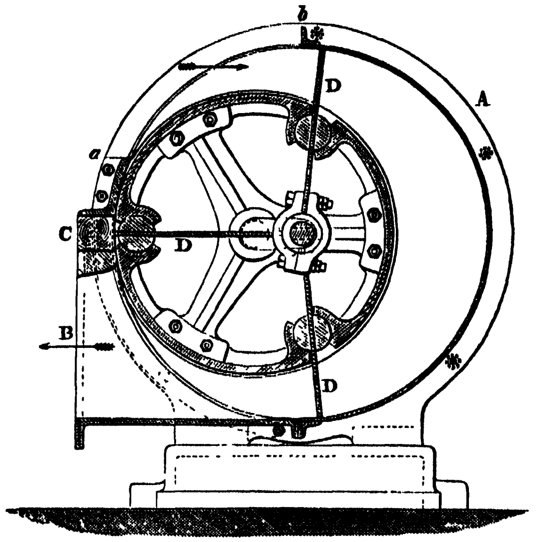

Fig. 5.—Section of an American Blowing-Machine.

The rotary blower, invented by Messrs Root of Connersville, Ind., is one which has of late years found extensive use both in America and Europe. The arrangement differs in some essential features from that of the ordinary fan; it acts by regular displacement of the air at each revolution, as shown in fig. 6. A pair of horizontal shafts geared together at both ends traverse a case of the form of two semi-cylinders separated by a rectangle equal in depth to the diameter of the semi-cylinders, and in width to the distance between the centres of the shafts. These shafts carry a pair of solid arms, each having a section somewhat resembling a figure of eight; the action of which, as they revolve, takes the air in by an aperture at the bottom of the machine, and expels it with considerable pressure, if required, at the top. The gearing outside serves merely to keep the revolving pieces in their proper position, and the power is applied directly to each shaft. One of these machines, employed to give the blast in a pneumatic railway under Broadway, New York, delivers, when worked to maximum speed, a volume of 100,000 cubic feet of air per minute. The engine is also much used in the Bessemer steel-works of this country.

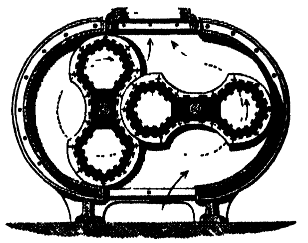

Fig. 6.—Rotary Blower.

Among the exhibits at a recent exhibition of the Franklin Institute in America, was shown a new form of blower, acting much on the same principle as the Root blower, but, according to the report of the committee, offering certain advantages over the latter. From a cross section of the chamber it appears that three drums of equal size are enclosed in it, two in a line below and one above; the upper one is provided with wings, and the two lower have wide slots along their entire length, allowing the wings to enter in the course of rotation. The function of the two lower drums is to supply alternately abutments to prevent the escape of the air. They are caused to revolve in proper relation with the motion of the upper drum by spur-wheels on the journals, which mesh into another spur-wheel on the shaft of the upper drum. In the moving parts of this machine there are no parts that come into actual contact except the teeth of the spur-wheels. The report allows the

superiority of this rotary blower of Baker, *inter alia*, as regards durability, little pulsation, absence of internal friction and of the need of lubrication, suitability for blowing either hot or cold air, and less power required for the amount of air discharged. A fuller account of it will be found in the *American Artisan* for March 1875.

For the arrangement of bellows in organs see the article ORGAN. (A. B. M.)

BELLUNO, the ancient *Belunum*, is the capital of a province of Northern Italy, and the seat of a bishop, situated at the confluence of the Piave and the Ardo, in long. 12° 8′ 46″ E. and lat. 46° 7′ 46″ N. Besides the cathedral, which was built by Palladius, there are fifteen churches, a theological seminary, a gymnasium, a theatre, and a library. A society of arts and sciences and a chamber of commerce have their meetings in the city. Water is supplied from the neighbouring hills by a remarkable aqueduct. The principal industries are the manufacture of silk, wax, leather, and pottery; and a considerable trade is carried on in wood. Population, 15,509.

BELON, PIERRE, French naturalist, was born about 1517 at the hamlet of Soulletière, in Maine. He studied medicine at Paris and took the degree of doctor. He afterwards travelled in Germany, and heard some lectures at the famous University of Wittenberg. On his return to France he was taken under the patronage of the Cardinal de Tournon, who furnished him with means for undertaking an extensive scientific journey. Belon started in 1546, travelled through Greece, Asia Minor, Egypt, Arabia, and Palestine, and returned in 1549. A full account of his travels, with illustrations, was published in 1553. It passed through several editions, and was translated into Latin and German. Belon, who was highly favoured both by Henry II. and by Charles IX., was assassinated one evening in April 1564, when coming through the Bois de Boulogne. Besides the narrative of his travels he wrote several scientific works of considerable value, particularly the *Histoire Naturelle des Estranges Poissons*, 1551, and *L'Histoire de la Nature des Oyseaux*, 1555.

BELPASSO, a town of Sicily, on the slopes of Etna, in the province of Catania, and about 8 miles from the city of that name. In 1669 it was destroyed by an eruption. The inhabitants rebuilt their town on a new site at Mezzo Campo, but, finding the locality unhealthy, they afterwards returned to their original position. Population, 7620.

BELPER, a market-town of Derbyshire, situated on the banks of the Derwent, which is here crossed by a stone bridge. It is 7 miles north of Derby, on the Midland Railway. For a considerable period one of the most flourishing towns in the country, it is principally indebted for its prosperity to the establishment of cotton-works by Messrs Strutt in 1777. It also manufactures linens, silks, hosiery, nails, and earthenwares: it has three churches, several chapels for Independents, Methodists, Baptists, &c., a mechanics' institution, and a subscription library. In the neighbourhood are the remains of a mansion where John of Gaunt used to reside. Population (1871), 8527.

BELSHAM, THOMAS, a Unitarian clergyman, was born at Bedford in 1750. He was educated at the Dissenting Academy at Daventry, where for seven years he acted as assistant tutor. After three years spent in a charge at Worcester, he returned as head of the Daventry Academy, a post which he continued to hold till 1789, when, having adopted Unitarian principles, he resigned all connection with the institution. He superintended during its brief existence a new college at Hackney, and was then called to the charge of the Gravel Pit congregation, which had been formerly held by the famous Priestley. In 1805 he was appointed to the Essex Street chapel, where he remained till his death in 1829. Belsham's first work of importance, *Review of Mr Wilberforce's Treatise entitled Practical View*, 1798, was written after his conversion to Unitarianism. His most popular work was the *Evidences of Christianity*; the most important was his translation and exposition of the Epistles of St Paul. He was also the author of a work on philosophy, *Elements of the Philosophy of the Human Mind*, 1801, which is entirely based on Hartley's psychology. Belsham is one of the most vigorous and able writers on the Unitarian side.

BELSHAM, WILLIAM, brother of the preceding, was born in 1752, and died in 1827. His productions were mainly historical and political writings, advocating the politics of the Whig party. Several detached historical treatises were collected together, and published in 1806 under the title, *History of Great Britain to the conclusion of the Peace of Amiens in* 1802, 12 vols.

BELSHAZZAR, the name of a Babylonian prince mentioned in the book of Daniel. According to the account in the fifth chapter of Daniel, Belshazzar was king of Babylon at the time of the capture of the city by the Medes and Persians, and was slain when the city was surprised during a festival. No ancient historian mentions the name of Belshazzar among the successors of Nebuchadnezzar, and there has been considerable controversy as to the identity of the unfortunate monarch. The successors of Nebuchadnezzar, according to the copyists of Berosus, were as follows:—Evil-merodach, two years, son of Nebuchadnezzar; Neriglissar, or Nergalsharezer, four years, son-in-law of Nebuchadnezzar; Laborosoarchod, nine months, son of Neriglissar; Nabonidus, seventeen years, not of the royal family. Niebuhr and some others identified Belshazzar with Evil-merodach; other scholars with Neriglissar; and a third section, including Ewald and Browne, identified him with Nabonidus. There is no necessity now to argue against these and similar views, as they are set aside by the Babylonian cuneiform inscriptions, which show that Bel-sar-uzur, or Belshazzar, was the name of the eldest son of Nabonidus, the last king of Babylon. In some of his latter inscriptions Nabu-nahid or Nabonidus mentions his eldest son Bel-sar-uzur in such terms as to lead to the impression that the young prince was associated with himself on the throne; and this explains several difficulties between the historians and the book of Daniel with respect to the capture of Babylon. After the defeat of the Babylonian forces Nabonidus fled to Borsippa, while the young prince Belshazzar was left in charge of Babylon, the capital, which was closely besieged by the Medes and Persians. The historians all say that Nabonidus, the last king of Babylon, submitted to the conquerors at Borsippa after the taking of his capital, while the book of Daniel states that Belshazzar was slain on the night of the capture of Babylon. These two statements have been supposed to contradict each other, but we now know that they refer to two totally distinct princes whose fates were quite different. The inscriptions of Nabonidus which mention Belshazzar are found on clay cylinders from Mugheir and other Chaldean sites, and they were first discovered and published by Sir Henry Rawlinson, to whom we owe this rectification in ancient history. One of these passages in a prayer reads: "Me Nabu-nahid, king of Babylon, from sin against thy great divinity, do thou save me, and health and long days numerous do thou multiply. And of Bel-sar-uzur,—my eldest son, the delight of my heart in the worship of thy great divinity, his heart do thou establish, and may he not consort with sinners." The other texts are after the same form, and give no new details as to Belshazzar,—the account in the fifth chapter of Daniel containing all that is known of his history. The numerous works written on this subject before the discovery of the cuneiform inscriptions are

now of little value; all that is known with any certainty on the matter will be found in Rawlinson's *Great Monarchies*, 2d edition, vol iii.

BELT, GREAT, and LITTLE BELT, two straits which connect the Baltic Sea with the Cattegat. The former, with a depth of from 5 to 20 fathoms, and a breadth of about 15 miles, runs, from S.S.E. to N.N.W., between the islands of Zealand and Fünen; while the Little Belt, which is only about half as wide, with a narrow entrance from the Cattegat, separates Fünen from the mainland of Schleswig. The navigation of both is rather dangerous for large vessels, owing to the number of sandbanks and small islands; and on that account the Sound, which lies to the east, is the channel preferred by shipping.

BELTANE, or BELTEIN, a festival originally common to all the Celtic peoples, of which traces were to be found in Ireland and the Highlands of Scotland down to the beginning of the present century. The name is compounded of *bel* or *beal*, the Celtic god of light, and *tin* or *teine*, meaning fire. The principal Beltane celebration was held annually in the beginning (generally on the first day) of May, though the name is also applied to a similar festival which occurred in the beginning of November. According to Cormac, archbishop of Cashel about the year 908, who furnishes the earliest notice of Beltane, it was customary to kindle, in very close proximity, two fires, between which both men and cattle were driven, under the belief that health was thereby promoted and disease warded of. (See *Transactions of the Irish Academy*, xiv. pp. 100, 122, 123.) Of the celebration in more recent times an account is given by Armstrong in his *Gaelic Dictionary*, *s. v.* "Bealtainn." The whole subject is fully treated by J. Grimm in his *Deutsche Mythologie*, c. xx.

BELUCHISTAN. See BALUCHISTAN.

BELVEDERE, a town of Italy, in the province of Calabria Citra, on the Mediterranean, 32 miles N.W. of Cosenza. It possesses a castle and a maidens' hospital, and is beautifully situated on the slope of a hill. Population between 5000 and 6000.

BELZONI, GIOVANNI BATTISTA, one of the most enterprising and successful Egyptian explorers, was born of humble parentage at Padua in 1778. When about eighteen years of age he appears to have removed to Rome, and for a short time became a monk. In 1798 the occupation of the city by the French troops drove him from Rome. He wandered through Holland, and in 1803 came to England. Here for some time he was compelled to find subsistence for himself and his wife, an Englishwoman, by exhibiting on the streets athletic exercises and feats of agility. Through the kindness of Mr Salt, who was ever afterwards his patron, he was engaged at Astley's amphitheatre, and his circumstances soon began to improve. In 1812 he set out on his travels, passing through Lisbon and Madrid to Egypt, where his friend, Mr Salt, was British consul. He was desirous of laying before the pasha Mehemet Ali a hydraulic machine for raising the waters of the Nile. Though the experiment with this engine was successful, the design was abandoned by the pasha, and Belzoni resolved to continue his travels. He visited Thebes and removed with great skill the colossal statue, commonly called young Memnon, which he shipped for England. He also pushed his investigations into the great temple of Edfoo, visited Elephantina and Philæ, discovered the temple of Abusimbel, made excavations at Carnac, and opened up a splendid tomb in the Beban-el-Molouk. He was the first to penetrate into the second great pyramid of Ghizeh, and the first to visit the oasis west of Lake Mœris. In 1819 he returned to England and published in the following year a most interesting account of his travels and discoveries. He also exhibited for some time at the Egyptian Hall facsimiles of the great tomb at Beban-el-Molouk. In 1823 he again set out for Africa, intending to penetrate to Timbuctoo. He reached Benin, but was seized with dysentery at a village called Gato, and died December 3, 1823.

BEMBO, PIETRO, Cardinal, was born at Venice on the 20th of May 1470. While still a boy he accompanied his father to Florence, and there acquired a love for that Tuscan form of speech which he afterwards cultivated in preference to the dialect of his native city. Having completed his studies, which included two years' devotion to Greek under Lascaris at Messina, he chose the ecclesiastical profession. After a considerable time spent in various cities and courts of Italy, where his learning already made him welcome, he accompanied Julio de' Medici to Rome, where he was soon after appointed secretary to Leo X. On the Pontiff's death he retired, with impaired health, to Padua, and there lived for a number of years engaged in literary labours and amusements. In 1529 he accepted the office of historiographer to his native city, and shortly afterwards was appointed librarian of St Mark's. The offer of a cardinal's hat by Pope Paul III. took him in 1539 again to Rome, where he renounced the study of classical literature and devoted himself to theology and classical history, receiving before long the reward of his conversion in the shape of the bishoprics of Gubbio and Bergamo. He died on the 18th of January 1547. Bembo, as a writer, is the *beau ideal* of a purist. The exact imitation of the style of the genuine classics was the highest perfection at which he aimed. This at once prevented the graces of spontaneity and secured the beauties of artistic elaboration. One cannot fail to be struck with the Ciceronian cadence that guides the movement even of his Italian writings.

His works include a *History of Venice* from 1487 to 1513, dialogues, poems, and what we would now call essays. Perhaps the most famous are a little treatise on Italian prose, and a dialogue entitled *Gli Asolani*, in which Platonic affection is explained and recommended in a rather long-winded fashion, to the amusement of the reader who remembers the relations of the beautiful Morosina with the author. The edition of Petrarch's *Italian Poems*, published by Aldus in 1501, and the *Terzerime*, which issued from the same press in 1502, were edited by Bembo, who was on intimate terms with the great typographer. See *Opere de P. Bembo*, Venice, 1729; Casa, *Vita di Bembo*, in 2d vol. of his works.

BENARES, a division, district, and city of British India, under the jurisdiction of the Lieutenant-Governor of the N.W. Provinces. BENARES DIVISION lies between 24° and 28° N. lat., and 82° and 85° E. long. It is bounded on the N. by Oudh, the Duáb, and Bundelkhand; on the E. by Nepál; on the S. by Bengal; and on the W. by Ríwa. It comprises the districts of Mirzápur, Gházípur, Azimgarh, Bastí, and Gorakhpur; has an area of 18,314 square miles; and a total population in 1872, of 8,178,147, of whom 7,286,415, or 89·1, were Hindus; 889,335, or 10·9, Mahometans; 1797 Christians and others.

BENARES, a DISTRICT of British India, in the division of the same name, under the jurisdiction of the Lieutenant-Governor of the N.W. Provinces, lies between 25° 7′ and 25° 32′ N. lat., and 82°45′ and 83° 38′ E. long. It is bounded on the N. by the British district of Jaunpur, on the N.E. by Gházípur, on the S.E. by Sháhábád, on the S. and S.W. by Mirzápur, and on the W. by Mirzápur and Jaunpur. The surface of the country is remarkably level, with numerous deep ravines in the calcareous conglomerate. This substratum when burnt affords good lime, and forms an excellent material for roads in its natural state. The soil is a clayey or a sandy loam, and very fertile, except in the tracts called Usur, which are impregnated with soda, nitre, and other salts.

Principal rivers—the Ganges; the Karamnásá, which separates Benares district from that of Sháhábád; the Gumtí, separating it from Jaunpur and Gházípur; the Barna-nálá, which falls into the Ganges near Benares city. Area, 996·19 square miles, of which 738 are under cultivation, 33·39 cultivable but not actually under cultiva-

tion, and the rest uncultivable waste. Population in 1872, 793,699, —90 per cent. being Hindus, 10 per cent. Mahometans, and Christians, &c., numbering 345. Principal crops—wheat, barley, pulse of various kinds, millet, maize, oil-seeds, tobacco, safflower, opium, sugar-cane, and castor-oil seed. Manufactures—sugar, opium, indigo, cotton cloth, coarse woollens, silk, and leather. Principal roads—(1), From Calcutta to Benares, and thence towards Allahábád; (2), a continuation of the Calcutta road through the town of Benares to the Sikrol cantonment, and thence towards Jaunpur; (3), from Gházípur to Mirzápur by Sikrol; and (4), from Benares city to Chanár. The East Indian Railway passes through the district, and the Ganges is navigable all the year round. Gross revenue in 1870–71, £140,617, of which £89,286, or 63 per cent., was derived from land. In 1872–73 the district contained 542 schools, attended by 12,782 pupils. Only two towns in the district contain above 5000 inhabitants, viz., Benares and Rámnagar. The climate of Benares is cool in winter, but very warm in the hot season. Mean temperature in 1872, 77·6° Fahr.; average annual rainfall for the nine years ending 1872, 34·03 inches.

From a very remote period Benares formed the seat of a Hindu kingdom, said to have been founded by one Kási Rájá, 1200 years B.C. Subsequently it became part of the kingdom of Kanauj, which in 1193 A.D. was conquered by Muhammad of Ghor. On the downfall of the Pathán dynasty of Dehli, about 1599, it was incorporated with the Mughul empire. On the dismemberment of the Dehli empire it was seized by Safdar Jang, the Nawáb Vazír of Oudh, by whose grandson it was ceded to the East India Company by the treaty of 1775. The subsequent history of Benares contains two important events,—the rebellion of Chait Sinh, occasioned by the unjust demands of Warren Hastings for money to carry on the Marhattá war; and the mutiny of the Native regiments in 1857, on which occasion the energy and coolness of the European officials (chiefly of General Neill) carried the district successfully through the storm.

BENARES, the most populous city in the North-Western Provinces, and the headquarters of the commissioner of the division, is situated on the north bank of the Ganges, in 25° 7′ N. lat. and 83° 4′ E. long. According to the census of 1872, the population amounted to 175,188, viz., 89,763 males, and 85,425 females,—133,549, or 76·23 per cent., being Hindus; 41,374, or 23·77 per cent., Mahometans; others, 265. Gross municipal income in 1871, £16,069; expenditure, £14,331; average rate of municipal taxation, 1s. 10d. per head.

The town of Benares—the religious centre of Hinduism —is one of the most ancient cities on the globe. The Rev. Mr Sherring, in his *Sacred City of the Hindus* (1868), states—"Twenty-five centuries ago, at the least, it was famous. When Babylon was struggling with Nineveh for supremacy, when Tyre was planting her colonies, when Athens was growing in strength, before Rome had become known, or Greece had contended with Persia, or Cyrus had added lustre to the Persian monarchy, or Nebuchadnezzar had captured Jerusalem and the inhabitants of Judea had been carried into captivity, she had already risen to greatness, if not to glory. Nay, she may have heard of the fame of Solomon, and have sent her ivory, her apes, and her peacocks to adorn his palaces; while partly with her gold he may have overlaid the temple of the Lord." Hiouen Thsang, the celebrated Chinese pilgrim, visited Benares in the 7th century A.D., and described it as containing thirty Buddhist monasteries, with about 3000 monks, and about a hundred temples of Hindu gods. Even after the lapse of so great a time the city is still in its glory, and as seen from the river it presents a scene of great picturesqueness and grandeur. The Ganges here forms a fine sweep of about 4 miles in length, the city being situated on the outside of the curve, on the northern bank of the river, which is the most elevated. It is about 3 miles in length, by 1 in breadth, rising from the river in the form of an amphitheatre, and is thickly studded with domes and minarets. The bank of the river is entirely lined with stone, and there are many very fine *gháts* or landing-places built by pious devotees, and highly ornamented. These are generally crowded with bathers and worshippers. Shrines and temples line the bank. The internal streets are so winding and narrow that there is not room for a carriage to pass, and it is difficult to penetrate them even on horseback. Their level is considerably lower than the ground-floors of the houses, which have generally arched rows in front, with little shops behind them; and above these they are richly embellished with verandahs, galleries, projecting oriel windows, and very broad overhanging eaves supported by carved brackets. The houses are built of Chanár stone, and are lofty—none being less than two stories high, most of them three, and several of five or six stories. The Hindus are fond of painting the outside of their houses a deep red colour, and of covering the most conspicuous parts with pictures of flowers, men, women, bulls, elephants, and gods and goddesses in all the multiform shapes known in Hindu mythology. The number of temples is very great; they are mostly small, and are placed in the angles of the streets, under the shadow of the lofty houses. Their forms are not ungraceful, and many of them are covered over with beautiful and elaborate carvings of flowers, animals, and palm branches, rivalling in richness and minuteness the finest specimens of Gothic or of Grecian architecture.

Benares, having from time immemorial been a holy city, contains a vast number of Bráhmans, who either subsist by charitable contributions, or are supported by endowments in the numerous religious institutions of the city. Hindu religious mendicants, with every conceivable bodily deformity, literally line the principal streets on both sides. Some have their legs or arms distorted by long continuance in one position; others have kept their hands clenched until the finger nails have pierced entirely through their hands. But besides an immense resort to Benares of poor pilgrims from every part of India, as well as from Thibet and Burmah, numbers of rich Hindus, in the decline of life, retire thither to pass the remainder of their days, or temporarily to wash away their sins in the sacred water of the Ganges. These devotees lavish large sums in indiscriminate charity, and it is the hope of sharing in such pious distributions that brings together the concourse of religious mendicants from all quarters of the country.

Besides its religious interest, Benares is important as a wealthy city and a place of considerable trade; the bázárs are filled with the richest goods, and there is a constant bustle of business in all the principal streets. A large trade is carried on in the sugar, saltpetre, and indigo which are produced in the district. Silk and shawls are manufactured in the city; and Benares is especially famous for its gold embroidered cloths, called *Kinkáb* (Kincob), and for its gold filagree work. A large quantity of English piece goods here finds a market, being either sold for consumption in the neighbourhood, or sent to other parts of the country. The principal English institution in Benares is the Government or Queen's College, as it is called, conducted by a staff of professors from England. There are two distinct and separate departments in the college—Sanskrit and English. The Sanskrit college was founded by Government in 1791. There are three missions in Benares—the Church of England, the London, and the Baptist Missionary Society. The mission in connection with the Church of England was established in 1817. The mission has a church capable of holding between 300 and 400 persons, two normal schools for training Christian teachers, a large college, and several girls' schools. The mission of the London Missionary Society was inaugurated in 1821, and is situated in the suburbs of the city. A substantial church was erected

about 1846. The mission of the Baptist Missionary Society was founded in 1817, originally as an outpost of the Scrampur mission. It maintains an orphanage for the support and education of native children. With regard to the civil station, which is situated a short distance from the town, Mr Sherring says,—

"The foreign residents of Benares live chiefly at Sikrol, an extensive suburb on the north-west side of the city. This station is divided by the Barná River, to the south of which the greater portion of the military cantonments, and buildings connected therewith, are situated, and likewise the English church, Government college, medical hall, the old mint, the residence of the Mahárájá of Benares, the missionaries of the Church of England and of the London and the Baptist Societies, the courts of the civil and sessions judge, the deputy-judge, and the judge of small causes. To the north of the river are the houses of the civil officers of Government, the courts of the commissioner of the division, and of the collector and other magistrates of the district; several bungalows inhabited by deposed Rájás and other natives; the Wards' Institution, for the residence of sons of native noblemen under special charge of Government, and while pursuing their studies at Queen's College; the beautiful public gardens, supported by subscription; the swimming bath; the jail, in which as many as 1700 prisoners are sometimes confined; the lunatic asylum, with 110 patients; the blind and leper asylum, with 130 inmates, founded in 1825 by Rájá Kálí Sankar Ghoshál; and the cemetery. A hospital and four dispensaries are situated in various parts of the city, and afford gratuitous relief to numerous patients daily."

BENAVENTE, a decayed town of Spain, in the province of Zamora, situated on a gentle eminence near the River Esla. It formerly gave title to the Pimentals, a powerful family of counts, which is now merged in that of the dukes of Osuña. The ancient castle still exists in a ruinous condition. Among the numerous churches, for which the town was once remarkable, are Santa Maria del Azogue, dating from the 12th and 13th centuries, and San Juan del Mercado, which once belonged to the Knights-Templars, and still contains some very old sepulchral monuments. Silk-spinning is carried on by the inhabitants, who number 4536.

BENBOW, John, English admiral, the son of a Shropshire gentleman, was born at Shrewsbury about 1650. He went to sea when very young, and at the age of thirty became master of a merchantman. When trading to the Mediterranean in 1686 he beat off a Sallee pirate with such bravery that James II., who took a keen interest in ships and seamen, made him captain of a man-of-war. On the accession of William III. he was employed to protect English commerce in the Channel, a duty which he vigilantly discharged. After taking part with great intrepidity in the bombardment of St Malo (1693), and superintending the blockade of Dunkirk (1696), he sailed in 1698 for the West Indies, where he compelled the Spaniards to restore several English vessels which they had seized. On his return he was appointed vice-admiral, and was frequently consulted by the king. In 1701 he was sent again to the West Indies, a station declined by his seniors from fear of the French strength in those waters. In August 1702 his ship, the "Breda," gave chase off Santa Martha to a French squadron under Du Casse; and although unsupported by his consorts, he kept up a running fight for five days with the most stubborn courage. While boarding the sternmost French vessel he received two severe wounds; and shortly afterwards his right leg was shattered by a chain-shot, despite which he remained on the quarter-deck till morning, when the flagrant disobedience of the captains under him, and the disabled condition of his ship, forced him reluctantly to abandon the chase. After his return to Jamaica, where his subordinates were tried by court-martial, he died of his wounds on November 4, 1702. He possessed inflexible resolution and great naval skill, and secured his high rank through his unaided merits. (*Cf.* Yonge's *Hist. of the British Navy*, vol. i.; Campbell's *British Admirals*, vol. iii.)

BENCH, or Banc, has various legal significations.

Free-Bench signifies that estate in copyhold-lands which the wife, being espoused a virgin, has, after the decease of her husband, for her dower, *dum sola et casta fuerit*, according to the custom of the manor. With respect to this free-bench different manors have different customs.

Queen's Bench is one of the three superior courts of Common Law at Westminster, the others being the Common Pleas and the Exchequer. Although for many years these tribunals have possessed co-ordinate jurisdiction, there are a few cases in which each possesses exclusive authority, and in point of dignity precedence is given to the Court of Queen's Bench, the Lord Chief-Justice of which is also styled Lord Chief-Justice of England, and is the highest permanent judge of the Crown. All three courts trace their origin to the *aula regia*. The Court of Exchequer attended to the business of the revenue, the Common Pleas to private actions between citizens, and the Queen's Bench retained criminal cases and such other jurisdiction as had not been divided between the other two courts. By 11 Geo. IV. and 1 Will. IV. c. 70, § 8, the Court of Exchequer Chamber was constituted as a court of appeal for errors in law in all three courts. Like the Court of Exchequers the Queen's Bench assumed, by means of an ingenious fiction, the jurisdiction in civil matters, which properly belonged to the Common Pleas. The functions peculiar to the Queen's Bench are its jurisdiction in criminal matters, and the general control it exercises over inferior magistrates and other public officers. Of late years the court has consisted of one Lord Chief-Justice and five *puisne* judges. Under the Judicature Act, 1873, the Court of Queen's Bench becomes the Queen's Bench Division of the High Court of Justice; and appeals will in future be taken to the Court of Appeal instead of the Exchequer Chamber.

The Court of Common Pleas is sometimes called the Common Bench.

Sittings in Banc (in the courts of Common Law) are the sittings of the full court for the hearing of motions, special cases, &c., as opposed to the *nisi prius* sittings for trial of facts, where usually only a single judge presides.

BENCHERS, in the Inns of Court, the senior members of the society, who are invested with the government of the body to which they belong.

BENCOOLEN, the chief town of a Dutch residency in the S.W. of Sumatra. It is situated on the coast at the mouth of a river of the same name, in 3° 50′ S. lat. and 102° 3′ E. long. The locality is low and swampy, and most of the houses are raised on bamboo piles. The bay is a mere open roadstead fringed with coral reefs, and landing is difficult on account of the surf. A lighthouse has been recently erected by the Dutch authorities. At one time there was a very extensive trade carried on with Bengal, the Coromandel coast, and Java, but it has greatly declined. The principal exports are pepper and camphor. The town, which was formerly 6 miles to the north, was removed to its present site in 1714. It is defended by a fort; and possesses an old and a new government-house, a council chamber and treasury, a hospital, &c. The church was destroyed by an earthquake in 1833. Bencoolen was formerly the chief establishment possessed by the English East India Company in the island, and for a few years constituted a distinct presidency. In 1719 the settlers were expelled by the natives, but were soon permitted to return. In 1760 all the English settlements on the coast of Sumatra were destroyed by a French fleet under Comte d'Estaing. They were afterwards re-established and secured to the British; but in 1825 they were finally ceded to the Netherlands in exchange for the Dutch settlements on the continent of India. Population of the district in 1871, 160 Europeans and 128,343 natives.

BENDER, a town of Russia, the capital of a district in the province of Bessarabia, situated on the right bank of the Dniester, 35 miles from Kisheneff, in 46° 49′ N. lat. and 29° 29′ E. long. It possesses three Greek churches, a Roman Catholic church, a dissenting place of worship, four synagogues, and a mosque. Its industrial establishments include a tobacco-factory, candle-works, and brick-kilns. An important trade is carried on by means of its harbour on the Dniester and the road that leads to Odessa,—the greater part of the ships discharging their cargoes here to be conveyed by land to Odessa and Jassy. The principal articles of trade are corn, wine, wool, cattle, tallow, and especially timber, which is floated down the Dniester. The citadel is separated from the town by an eminence, which bears the name of the Suwaroff mound; in its eastern part is a wooden castle with towers. There are also four suburbs to the town, which in 1867 had a population of 24,443, the greater proportion of them being Jews. As early as the 12th century the Genoese had a settlement on the site of Bender. The Moldavians called the place Teegeen, and the name of Bender was only bestowed by the Turks in the end of the 14th century. In 1709 Charles XII., after the defeat of Poltava, collected his forces here in a camp which they called New Stockholm, and continued there till 1711. Bender was thrice taken by the Russians,—by Panim in 1770, Potemkin in 1789, and Meyendorf in 1806,—but it was not held permanently by Russia till the Bucharest peace of 1812.

BENDER-ABBASI, a town of Persia in the province of Kirman, on the northern shore of the Persian Gulf, in 27° 13′ N. lat. and 56° 7′ E. long., about 12 miles N.W. of the island of Ormuz. It is surrounded with walls, but the houses are of a very poor description. The old Dutch factory is still standing, and serves as the occasional residence of the Imam of Mascat, to whose domain the town belongs. There is a comparatively small trade in the export of tobacco and fruits and the import of cotton-cloth and pottery. The port is shallow and inconvenient; and it is evident that changes of the coast line by silting up and denudation have considerably altered the character of the place since the time when, under the name of Gombroon, it ranked as one of the first seaports of Persia. In 1612 the Portuguese had established Fort Komoran here, but it was destroyed in 1614, and they were expelled by Shah Abbas I. The English, however, were permitted to build a factory, and about 1620 the Dutch obtained the same privilege. On the capture of the island of Ormuz in 1622 by the English and Persians, a large portion of its trade was diverted to the town, which derived its name of Bender-Abbasi, or *Harbour of Abbas*, from the shah. During the rest of the 17th century the traffic was very great, all the neighbouring nationalities and merchants from the principal countries of Europe frequenting its markets; but in the 18th century this prosperity declined, and most of the trade was removed to Bushire. In 1759 the English factory was destroyed by the French; and though it was afterwards re-established, it has long been abandoned. The ruins of the factory and other buildings lie to the west of the present town. Population about 9000.

BENEDICT, St, the founder of the celebrated Benedictine order, is the most illustrious name in the early history of Western monasticism. To him more than to any other the monastic system, which was destined to exercise such an influence for centuries, owes its extension and organization. Benedict was born at Nursia in Umbria about the year 480. He belonged to an old Italian family, and was early sent to Rome to be educated. But the disorder and vices of the capital drove him into solitude while still a youth. It was a time of public peril and social ruin. The Roman empire was crumbling to pieces, shaken by the successive inroads of barbarians, and a prey to every species of violence and corruption. Young Benedict fled from the wickedness around him. He gave up his literary studies and preferred to be wisely ignorant (*scienter nesciens*). This is the statement of his biographer Gregory the Great, from whom come all the details that we know of Benedict's life. It is needless to say that many of these details are of such a character that it is impossible for modern historical criticism to accept them in their literal meaning. It is of no use, however, trying to disentangle the truth from the falsehood. The reader can easily make allowance for the imaginative exaggerations of the story.

When Benedict fled from Rome he took refuge in a solitary gorge formed by the Anio, in its picturesque course, about 40 miles from the city. There, in a dark inaccessible grotto near Subiaco, he found seclusion and shelter. A neighbouring monk supplied him with food let down by a rope, with a small bell attached, which gave notice of the approach of the food. Once the devil broke the rope, but his malice was foiled by the pious ingenuity of the monk. Other and graver dangers assailed him. The Evil One took the shape of a beautiful woman, with whose image the youthful recluse had been familiar in Rome, and so worked upon his senses that he was on the point of abandoning his solitude in search of the beauty which haunted him. But summoning all his fortitude he stripped himself of the vestment of skins which was his only covering, rushed naked amongst the thorns and briars which grew around his retreat, and rolled himself amongst them till he had extinguished the impure flame which devoured him. No impulses of sensual passion ever revisited him. But trials of a different kind assailed him. After spending about three years in retirement a neighbouring convent of monks insisted upon choosing him as their head. He warned them of the severity of the rule he would be bound to exercise, but they would not be dissuaded from their purpose. He had hardly commenced his office, however, when they broke out into fierce resentment against him, and attempted to poison him. The cup containing the poison was no sooner taken into the hands of Benedict than it burst asunder; and, calmly reproving them for their ingratitude, he left them and withdrew once more into his solitude.

By this time, however, the fame of Benedict had spread, and it was impossible for him to remain inactive. Multitudes gathered around him, and no fewer than twelve select cloisters were planted in the lonely valley of the Anio and on the adjacent heights. Young patricians from Rome and elsewhere were attracted to these fraternities; and amongst them one of the name of Maurus (St Maur), who began to share in popular esteem something of the sanctity and miraculous endowments of Benedict, and who was destined to be his successor. But with increasing fame came also jealousy of his position and duties. A renewed attempt was made by an envious priest to administer poison to the saint; and, miraculous interpositions having again come to his rescue, the same priest, by name Florentius, had recourse to the diabolical device of sending seven lewd girls within the precincts of the monastery, to seduce the monks by their gestures and sports. Benedict determined to depart from a neighbourhood so full of danger, notwithstanding the long period of thirty years during which he had laboured to consecrate it and spread abroad the blessings of an ascetic Christianity. He journeyed southwards, and at length settled at Monte Cassino, an isolated and picturesque hill near the river Garigliano. There at this time an ancient temple of Apollo still stood, to which the ignorant peasants brought their offerings. Benedict, in his holy enthusiasm, proceeded

to demolish the temple and to erect in its place two oratories, one to St John the Baptist and the other to St Martin, whose ascetic fame had travelled to Italy from the south of Gaul. Around these sacred spots gradually rose the famous monastery which was destined to carry the name of its founder through the Christian world, and to give its laws, as Milman says, "to almost the whole of Western monasticism."

Benedict survived fourteen years after he had begun this great work. His sanctity and influence grew with his years, in illustration of which it is told how the barbarian king Totila, who made himself master of Rome and Italy, sought his presence, and, prostrating himself at his feet, accepted a rebuke for his cruelties, and departed a humbler and better man. His last days were associated with the love and devotion of his sister Scolastica, who too had forsaken the world and given herself to a religious life with an enthusiasm and genius for government hardly less than his own. She had established a nunnery near Monte Cassino; but the rules of the order permitted the brother and sister to meet only once a year. He had come to pay his accustomed visit. They had spent the day in devout converse, and, in the fulness of her affection, Scolastica entreated him to remain, and "speak of the joys of heaven till the morning." Benedict was not to be prevailed upon, when his sister burst into a flood of tears, and bowed her head in prayer. Immediately the heavens became overcast; thunder was heard, and the rain fell in torrents, so that it was impossible for Benedict to depart for the night, which was spent in spiritual exercises. Three days later Benedict saw in vision the soul of his sister entering heaven, and in a few days afterwards his own summons came. He died standing, after partaking of the holy communion, and was buried by the side of his sister.

The Benedictines, or followers of St Benedict, were those who submitted to the monastic rule which he instituted. This rule will be generally described in the article on Monasticism. It is sufficient to say here that its two main principles were labour and obedience. It was the distinction of Benedict that he not merely organized the monks into communities, but based their community-life, in a great degree, on manual labour, in contrast to the merely meditative seclusion which had hitherto been in vogue both in the East and the West. Probably, not even the founder himself foresaw all the prospective advantages of his law, which was destined not merely to make many a wilderness and solitary place to rejoice with fertility, but to expand, moreover, into a noble intellectual fruitfulness, which has been the glory of the Benedictine order. The law of obedience was absolute, but was tempered by the necessity on the part of the superior of consulting all the monks assembled in a council or chapter upon all important business. The abbot or superior was also elected by all the monks, whose liberty of choice was unrestricted. No right of endowment properly subsisted within the monastery; and the vow of *stability* once undertaken after the expiry of the year of novitiate could never be recalled. Food and clothing were of the simplest kind, and all duly regulated; and the intervals of labour were relieved by a continually recurring round of religious service from prime to evensong. The Benedictine rule spread almost universally in the West,—not in rivalry of any other rule, but as the more full and complete development of the monastic system. In France and England especially it took rapid root; and "in every rich valley, by the side of every clear and deep stream, arose a Benedictine abbey"—a centre of local good and Christian civilization. See Abbey. (J. T.)

BENEDICT. Fourteen popes bore the name of Benedict—

Benedict I. (573–8) succeeded John III., and occupied the Papal chair during the incursions of the Lombards, and during the series of plagues and famines which followed these invasions. (Paul. Diacon., *De Gest. Longob.*, ii. 10.)

Benedict II. (684–685) succeeded Leo II., but although chosen in 683 he was not ordained till 684, because the leave of the Emperor Constantine was not obtained until some months after the election. (Paul. Diacon., *op. cit.* vi. 53.)

Benedict III. (855–858) was chosen by the clergy and people of Rome, but the election was not confirmed by the Emperor Lothair, who appointed an anti-pope, Anastasius. Benedict was at last successful, and the schism helped to weaken the hold of the emperors upon the popes. The mythical Pope Joan is usually placed between Benedict and his predecessor Leo IV.

Benedict IV. (900–903).

Benedict V. (964–965) was elected by the Romans on the death of John XII. The Emperor Otho did not approve of the choice, and carried off the pope to Hamburg, where he died.

Benedict VI. (972–974) was chosen with great ceremony and installed pope under the protection of the Emperor Otho the Great. On the death of the emperor the turbulent citizens of Rome renewed their outrages, and the pope himself was strangled by order of Crescentius, the son of the notorious Theodora.

Benedict VII. (975–983) belonged to the noble family of the counts of Tusculum, and governed Rome quietly for nearly nine years, a somewhat rare thing in those days.

Benedict VIII. (1012–1024), also of the family of Tusculum, was opposed by an anti-pope, Gregory, who compelled him to flee from Rome. He was restored by Henry of Saxony, whom he crowned emperor in 1014. In his pontificate the Saracens began to attack the southern coasts of Europe, and effected a settlement in Sardinia. The Normans also then began to settle in Italy.

Benedict IX. (1033–1056), the son of Alberic, count of Tusculum, and nephew of Benedict VIII., obtained the Papal chair by simony. He was deposed in 1044, and Sylvester was chosen in his stead. The result was a long and disgraceful schism (*cf.* Mittler, *De Schismate in Eccl. Rom. sub Pontif. Bened. IX.*)

Benedict X. (1058–9) scarcely deserves to be reckoned a pope. He reigned nine months. It is important, however, to remember that his election is one of the latest made by Roman factions, and under his successor the mode of election by the cardinals was adopted.

Benedict XI. (1303–1304) succeeded the famous Boniface VIII., but was unable to carry out his Ultramontane policy. He released Philip the Fair of France from the excommunication laid on him by Boniface, and practically ignored the bull *Unam Sanctam.* The popes who immediately succeeded him were completely under the influence of the kings of France, and removed the Papal seat from Rome to Avignon.

Benedict XII. (1334–1342) succeeded Pope John XXII., but did not carry out the policy of his predecessor. He practically made peace with the Emperor Louis, and as far as possible came to terms with the Franciscans, who were then at war with the Roman see. He was a reforming pope, and tried to curb the luxury of the monastic orders, but without much success. (Baluze, *Vitæ Pontif. Avenion.*, i.)

Benedict XIII. Two popes assumed this title—(1.) *Peter de Luna*, a Spaniard, who was chosen by the French cardinals on the death of Clement VII. in 1394. On the death of Urban V. in 1389 the Italian cardinals had chosen Boniface IX.; the election of Benedict therefore perpetuated the great schism. The greater portion of the church refused to recognize him, and in 1397 the French Church, which had supported him, withdrew from allegiance to both popes, and in 1398 Benedict was imprisoned in his own palace at

Avignon. The Council of Constance brought this state of matters to an end. Benedict abdicated in 1417, but was recognized by Scotland and Spain until his death in 1424. His name does not appear in the Italian list of popes. (*Cf.* Dupuy, *Hist. du Schisme*, 1378–1428). (2.) *Vincenzo Marco Orsini*, who succeeded Innocent XIII. in 1724. He at first called himself Benedict XIV., but afterwards altered the title. He was a reforming pope, and endeavoured to put down the luxury of the Italian priesthood and of the cardinalate. He died in 1730.

BENEDICT XIV. (1740–1758) belonged to a noble family of Bologna. Elected to the Papal chair in a time of great difficulties, chiefly caused by the disputes between Roman Catholic nations about the election of bishops, he managed to overcome most of them. The disputes of the Holy See with Naples, Sardinia, Spain, Venice, and Austria were settled. Perhaps the most important act of his pontificate was the promulgation of his famous laws about missions in the two bulls, *Ex quo singulari* and *Omnium solicitudinum*. In these bulls he denounced the custom of accommodating Christian words and usages to express heathen ideas and practices, which had been extensively done by the Jesuits in their Indian and Chinese missions. The consequence of these bulls was that most of the so-called converts were lost to the church.

BENEFICE, a term first applied under the Roman empire to portions of land, the usufruct of which was granted by the emperors to their soldiers or others for life, as a reward or *beneficium* for past services, and as a retainer for future services. A list of all such *beneficia* was recorded in the *Book of Benefices* (*Liber Beneficiorum*), which was kept by the principal registrar of benefices (*Primiscrinius Beneficiorum*). In imitation of the practice observed under the Roman empire, the term came to be applied under the feudal system to portions of land granted by a lord to his vassal for the maintenance of the latter on condition of his rendering military service; and such grants were originally for life only, and the land reverted to the lord on the death of the vassal. In a similar manner grants of land, or of the profits of land, appear to have been made by the bishops to their clergy for life, on the ground of some extraordinary merit on the part of the grantee. The validity of such grants was first formally recognized by the Council of Orleans, 511 A.D., which forbade, however, under any circumstances, the alienation from the bishoprics of any lands so granted. The next following Council of Orleans, 533, broke in upon this principle, by declaring that a bishop could not reclaim from his clergy any grants made to them by his predecessor, excepting in cases of misconduct. This innovation on the ancient practice was confirmed by the subsequent Council of Lyons, 566, and from this period these grants ceased to be regarded as personal, and their substance became annexed to the churches,—in other words, they were henceforth enjoyed *jure tituli*, and no longer *jure personali*. How and when the term *beneficia* came to be applied to these episcopal grants is uncertain, but they are designated by that term in a canon of the Council of Mayence, 813.

The term benefice, according to the canon law, implies always an ecclesiastical office, *propter quod beneficium datur*, but it does not always imply a cure of souls. It has been defined to be the right which a clerk has to enjoy certain ecclesiastical revenues on condition of discharging certain services prescribed by the canons, or by usage, or by the conditions under which his office has been founded. These services might be those of a secular priest with cure of souls, or they might be those of a regular priest, a member of a religious order, without cure of souls; but in every case a benefice implied three things: 1. An obligation to discharge the duties of an office, which is altogether spiritual; 2. The right to enjoy the fruits attached to that office, which is the benefice itself; 3. The fruits themselves, which are the temporalities. By keeping these distinctions in view, the right of patronage in the case of secular benefices becomes intelligible, being in fact the right, which was originally vested in the donor of the temporalities, to present to the bishop a clerk to be admitted, if found fit by the bishop, to the office to which those temporalities are annexed. Nomination or presentation on the part of the patron of the benefice is thus the first requisite in order that a clerk should become legally entitled to a benefice. The next requisite is that he should be admitted by the bishop as a fit person for the spiritual office to which the benefice is annexed, and the bishop is the judge of the sufficiency of the clerk to be so admitted. By the early constitutions of the Church of England a bishop was allowed a space of two months to inquire and inform himself of the sufficiency of every presentee, but by the ninety-fifth of the canons of 1604 that interval has been abridged to twenty-eight days, within which the bishop must admit or reject the clerk. If the bishop rejects the clerk within that time he is liable to a *duplex querela* in the ecclesiastical courts, or to a *quare impedit* in the common law courts, and the bishop must then certify the reasons of his refusal. In cases where the patron is himself a clerk in orders, and wishes to be admitted to the benefice, he must proceed by way of petition, instead of by deed of presentation, reciting that the benefice is in his own patronage, and petitioning the bishop to examine him and admit him. Upon the bishop having satisfied himself of the sufficiency of the clerk, he proceeds to institute him to the spiritual office to which the benefice is annexed, but before such institution can take place, the clerk is required to make a declaration of assent to the Thirty-nine Articles of Religion and to the Book of Common Prayer according to a form prescribed in the Clerical Subscription Act, 28 and 29 Vict. c. 122, to make a declaration against simony in accordance with that Act, and to take and subscribe the oath of allegiance according to the form in 31 and 32 Vict. c. 72. The bishop, by the act of institution, commits to the clerk the cure of souls attached to the office to which the benefice is annexed. In cases where the bishop himself is patron of the benefice, no presentation or petition is required to be tendered by the clerk, but the bishop having satisfied himself of the sufficiency of the clerk, collates him to the benefice and office. It is not necessary that the bishop himself should personally institute or collate a clerk, he may issue a fiat to his vicar-general, or to a special commissary for that purpose. After the bishop or his commissary has instituted the presentee, he issues a mandate under seal, addressed to the archdeacon or some other neighbouring clergyman, authorizing him to induct the clerk into his benefice,—in other words, to put him into legal possession of the temporalities, which is done by some outward form, and for the most part by delivery of the bell-rope to the clerk, who thereupon tolls the bell. This form of induction is required to give the clerk a legal title to his "*beneficium*," although his admission to the office by institution is sufficient to vacate any other benefice which he may already possess.

By the Lateran Council of 1215, which was received by the Church of England, no clerk can hold two benefices with cure of souls, and if a beneficed clerk shall take a second benefice with cure of souls, he vacates *ipso facto* his first benefice. Dispensations, however, could be easily obtained from Rome, before the reformation of the Church of England, to enable a clerk to hold several ecclesiastical dignities or benefices at the same time, and by 25 Henry VIII. c. 21, the power to grant such dispensations, which had been exercised previously by the court of Rome, was

transferred to the archbishop of Canterbury, certain ecclesiastical persons having been declared by a previous statute (21 Henry VIII. c. 13) to be entitled to such dispensations. The system of pluralities carried with it, as a necessary consequence, systematic non-residence on the part of many incumbents, and delegation of their spiritual duties in respect of their cures of souls to assistant curates. The evils attendant on this system were found to be so great that in 1838 an Act of Parliament, 1 and 2 Vict. c. 106, was passed to abridge the holding of benefices in plurality, and it was enacted that no person should hold under any circumstances more than two benefices, and this privilege was made subject to the restriction that his benefices were within ten statute miles of each other. By a subsequent Act, 13 and 14 Vict. c. 98, the restriction has been further narrowed, and no spiritual person may now hold two benefices except the churches of such benefices are within three miles of each other by the nearest road, and the annual value of one of such benefices does not exceed one hundred pounds. By this statute the term benefice is defined to mean benefice with cure of souls and no other, and therein to comprehend all parishes, perpetual curacies, donatives, endowed public chapels, parochial chapelries, and chapelries or districts belonging or reputed to belong, or annexed or reputed to be annexed, to any church or chapel.

A benefice is avoided or vacated—1, by death; 2, by resignation, if the bishop is willing to accept the resignation; 3, by cession, upon the clerk being instituted to another benefice or some other preferment incompatible with it; 4, by deprivation and sentence of an ecclesiastical court; 5, by act of law in consequence of simony; 6, by default of the clerk in neglecting to read publicly in the church the Book of Common Prayer, and to declare his assent thereto within two months after his induction, pursuant to 13 and 14 Car. II. c. 4, § vi.

The number of benefices with or without cure of souls in the Church of England, before the first statute to abridge pluralities was passed in 1838 (1 and 2 Vict. c. 106), was about 11,000. These benefices were served by some 10,000 clergy, of whom rather more than 5000 were incumbents holding one or more livings, and some of them altogether non-resident; the remainder were assistant curates, for the most part residing in one parish and having full charge of another. The effect of the Pluralities Act in the course of about 30 years has been to produce a remarkable and most salutary change. It was computed in 1867 that the parochial benefices were 12,888 in number, and the parochial clergy 17,869, of whom 4981 only were assistant-curates. The patronage of 6403 of these benefices was in private hands, whilst the patronage of 6485 was at the disposal of the Crown, or of public bodies or public functionaries. An approximate statement of the yearly value of all the benefices in England and Wales, the number of which has undergone a considerable increase since 1867, was drawn up in 1874 by Mr J. K. Aston for a select committee of the House of Lords on Church Patronage. From this statement it appears that the yearly value of all the benefices in public patronage is about £1,825,805, whilst the value of those in private patronage is about £1,893,226; but in Mr Aston's opinion these estimates are below the actual value. (T. T.)

BENEKE, Friedrich Eduard, a distinguished German psychologist, was born at Berlin on the 17th February 1798. He was educated under Bernhardi at the Gymnasium Fredericianum, and studied at the universities of Halle and Berlin. He directed his attention in the first instance to theology, coming under the influence of Schleiermacher and De Wette, but afterwards to pure philosophy, studying particularly English writers, and the German modifiers of Kantianism, such as Jacobi, Fries, and Schopenhauer. In 1820 he published his *Theory of Knowledge*, his *Empirical Psychology as the Foundation of all Knowledge*, and his inaugural dissertation *De Veris Philosophiæ Initiis*. In all these writings appeared very strongly his fundamental view, that philosophical speculation must be limited to the facts of inner experience, and that a true psychology, which is the basis of all knowledge, must be formed by treating these facts according to the rigid methods of physical science. His marked opposition to the philosophy of Hegel, then dominant in Berlin, came to the front still more clearly in the short tract, *New Foundation of Metaphysics*, intended to be the programme for his lectures as *privat-docent*, and in the able treatise, *Ground-work of a Physic of Ethics*, written in direct antagonism to Kant's *Metaphysic of Ethics*, and attempting to deduce ethical principles from a basis of empirical feeling. In the same year (1822) his lectures were prohibited at Berlin, according to his own belief through the influence of Hegel with the Prussian authorities, who also prevented him from obtaining a chair from the Saxon Government. He retired to Göttingen, lectured there for some years, and was then allowed to return to Berlin. In 1832 he received an appointment as *Professor Extraordinarius* in the university, which he continued to hold till his death. On 1st March 1854 he disappeared from his home; and some months later his body was found in the canal near Charlottenburg. There was some suspicion that he had committed suicide in a fit of mental depression.

Beneke was a most prolific writer, and besides the works mentioned above, published large treatises in the several departments of philosophy, both pure and as applied to education and ordinary life. A complete list of his writings will be found in the appendix to Dressler's edition of the *Lehrbuch der Psychologie als Naturwissenschaft*, 1861.

The distinctive peculiarity of Beneke's system consists, first, in the firmness with which he maintained, and the consistency with which he carried out the proposition, that in empirical psychology is to be found the basis of all philosophy; and secondly, in his rigid treatment of mental phenomena by the genetic, or, as Professor Bain has called it, the natural history method. According to him, the formed or perfected mind with its defined faculties is a development from simple elements, and the first problem of philosophy is the determination of these elements and of the laws or processes by which the development takes place. In his *Neue Psychologie* (essays iii., viii., and ix.), he clearly marked out his position with regard to his predecessors and contemporaries, and both there and in the introduction to his *Lehrbuch*, signalized as the two great stages in the progress of psychology the negation of innate ideas by Locke, and of faculties, in the ordinary acceptation of the term, by Herbart. The next step was made by himself, when he insisted that psychology must be treated as one of the natural sciences. As is the case with them, its content is given by experience alone, and differs from theirs only in being the object of the internal as opposed to the external sense. But by a scientific psychology Beneke in no wise meant what is now almost invariably thought of under that designation, a psychology founded on physiology. These two sciences, in his opinion, had quite distinct provinces, and gave no mutual assistance. Just as little help is to be expected from the science of the body as from mathematics and metaphysics, both of which had been pressed by Herbart into the service of psychology. The true method of study is that applied with so much success in the physical sciences,—critical examination of the given experience, and reference of it to ultimate causes, which may not be themselves perceived, but are nevertheless hypotheses necessary to account for the facts. (See on method, *Neue Psych.*, essay i.)

Beneke, therefore, starting from the two assumptions that there is nothing, or at least no formed product, innate in the mind, and that definite faculties do not originally exist, and from the fact that our minds nevertheless actually have a definite content and definite modes of action, proceeds to state somewhat dogmatically his scientifically verifiable hypotheses as to the primitive condition of the soul, and the laws according to which it develops. Originally the soul is possessed of, or is, an immense variety of powers, faculties, or forces (conceptions which Beneke, in opposition to Herbart, holds to be metaphysically justifiable), differing from one another only in tenacity, vivacity, receptivity, and grouping. These primitive immaterial forces, so closely united as to form but one being (essence), acquire definiteness of form through the action upon them of *stimuli* or excitants from the outer world. This action of external impressions which are appropriated by the internal powers, is the first fundamental process in the genesis of the completed mind. If the union of impression and faculty be sufficiently strong, consciousness (not *self*-consciousness) arises, and definite sensations and perceptions begin to be formed. These primitive sensations, however, are not to be identified with the sensations of the special senses, for each of these senses is a system of many powers which have grown into a definite unity, have been educated by experience. From various facts of ordinary experience it must be concluded that a second fundamental process is incessantly going on, viz., the formation of new powers of faculties, which takes place principally during sleep. The third and most important process results from the fact that the combination between stimulus and power may be weak or strong,

if weak, then the two elements are said to be movable, and they may flow over from one to another of the already formed psychical products. Any formed faculty does not cease to exist on the removal of its stimulus; in virtue of its fundamental property, *tenacity*, it sinks back as a trace (*Spur*) into unconsciousness, whence it may be recalled by the application to it of another stimulus, or by the attraction towards it of some of the movable elements or newly-formed original powers. These traces and the flowing over of the movable elements are the most important conceptions in Beneke's psychology; by means of them he gives a rationale of reproduction and association, and strives to show that all the formed faculties are simply developments from traces of earlier processes. Lastly, similar forms, according to the degree of their similarity, attract one another or tend to form closer combinations.

All psychical phenomena are explicable by the relation of impression and power, and by the flow of movable elements; the whole process of mental development is nothing but the result of the action and interaction of the above simple laws. In general this growth may be said to take the direction of rendering more and more definite by repetition and attraction of like to like the originally indefinite activities of the primary faculties. Thus the sensations of the special senses are gradually formed from the primary sensuous feelings (*Sinnliche Empfindungen*); concepts are formed from intuitions of individuals by the attraction of the common elements, and the consequent flow towards them of movable forms. Judgment is the springing into consciousness of a concept alongside of an intuition, or of a higher concept alongside of a lower. Reasoning is merely a more complex judgment. Nor are there special faculties of judging or reasoning. The understanding is simply the mass of concepts lying in the background of unconsciousness, ready to be called up and to flow with force towards anything closely connected with them. Even memory is not a special faculty; it is simply the fundamental property of tenacity possessed by the original faculties. The very distinction between the great classes, Knowledge, Feeling, and Will, may be referred to elementary differences in the original relations of faculty and impression.

To follow Beneke into the details of any one of his psychological developments would be impossible within moderate compass. It may be sufficient to say, that on nearly all questions concerning the psychical mechanism, his works contain a mass of unusually rich and instructive material. They are particularly deserving of careful comparison with the association psychology of modern British thinkers, most of whose results and processes will be found there thoroughly handled and worked into a comprehensive system.

In logic, metaphysics, and ethics, Beneke's speculations are completely dependent on the results of the psychological analysis. Thus thinking has been by him separated into analytical and synthetical. The first, which consists essentially in the subsumption of one concept under another, is the subject of elementary, pure, or formal logic, which, as an art, has to lay down the universal rules according to which such subsumption takes place. Logical reasoning, which adds nothing to our knowledge, but merely clears it up, is at bottom a substitution of one notion for another. In the elaborate theory of syllogism, founded on this principle, Beneke to some extent anticipates Hamilton's New Analytic. (It cannot, however, be thought that Hamilton borrowed his principle from Beneke, as the latter seems to have suspected;—see Dressler's remark, *Lehrbuch der Psy.*, 299. The two approached the matter from quite different sides, and the peculiarity of Hamilton's system, the definite. explicit, quantification of the predicate, is by no means necessarily implied in anything said by Beneke.) Synthetical thinking, on the other hand, leads to new knowledge, but in its progress it makes use of principles involving the relation of thought to existence, and which, therefore, find justification in metaphysics. In that science Beneke's fundamental proposition is that in inner experience we cognize things as they are, whereas in outer experience we only know their effects. Real being is given in our intuitions, from which we gradually form a notion of self, and then of other conscious beings like ourselves. The inference to the real existence of external things is an unconscious reasoning, involving the same elements as the inference to the existence of other conscious beings. The relations which give definiteness and universality to experience, such as substance and cause, are known directly in inner experience in the systematic relations of the several psychical elements, and are transferred by us to outer beings. In this part of his metaphysical theory Beneke owes much to Schleiermacher.

In his ethical theory, which is worked out with great fulness, and which was, in his own opinion, his most valuable contribution to philosophy, Beneke is thoroughly empirical. The worth of an object is defined to be the degree of pleasurable feeling with which it affects us, and ethical judgments are founded on the relations of worth among the feelings with which we regard objects. There is a gradation of moral worth, because there are higher and lower faculties; and, as the mental constitutions of all men are fundamentally alike, this gradation of worth becomes a *norm* or general rule for estimating moral qualities. An estimate founded on this normal scale appears as morally necessary, or as duty.

The special value of Beneke's works, as has been already said, consists in the many specimens of acute psychological analysis scattered throughout them. As a complete explanation of psychical facts, the theory seems singularly defective. The original hypotheses, peculiar to Beneke and on which the whole depends, are hastily assumed, are never subjected to critical examination, and after all, like Locke's earlier theory, rest on a clumsy mechanical metaphor. As is the case with all empirical theories of mental development, the higher categories or notions, which are apparently shown to result from the simple elements, are really presupposed at every step. Particularly unsatisfactory is the account of consciousness, which is said to arise from the union of impression and faculty. The necessity of consciousness for any mental action whatsoever is apparently granted, but the conditions involved in it are never discussed or referred to. So too the explanation of the origin of the notions, substance and cause, always a crucial test for an empirical theory, is completely irreconcilable with the fundamental principle of the system. The same defect appears in the account of ethical judgment; no amount of empirical fact can ever yield the notion of absolute duty. It is not, perhaps, to be altogether attributed to the ideal character of German speculation, that Beneke has been almost entirely neglected, and that his results have found acceptance mainly with practical teachers. Undoubtedly, for the science of education his minute analysis of temperament and careful exposition of the means whereby the young, unformed mind may be trained are of infinite value; but the truth of many of his doctrines on these points lends no support to the fundamental hypotheses, from which indeed they might be almost entirely severed.

Among German writers not professed followers of Beneke, but who have been largely influenced by him, may be mentioned Ueberweg (particularly in the first part of his Logic) and Fortlage. In England, perhaps the only writer who shows traces of acquaintance with his works is Morell (*Introd. to Mental Philosophy*). The most eminent members of the school are Dressler (whose *Beneke oder Seelenlehre als Naturwissenschaft* is an admirable exposition), Dittes, and Raue. The compendium by the last-named author has passed through four editions in Germany, and has been translated into French, Flemish, and English. The English translation, *Elements of Psychology*, 1871, gives a lucid and succinct view of the whole system. (R. AD.)

BENEVENTO, a city of Italy, the capital of a province, situated on a hill near the confluence of the Calore and the Sabato, 32 miles N.E. of Naples. The town is surrounded by walls, and was formerly defended by a castle of the 12th century, which now contains Government offices and a prison. It occupies the site of the ancient *Beneventum*, and is largely built of its ruins. Except Rome, few cities can boast of so many remains of antiquity. Of these the most beautiful and perfect is the arch of Trajan, erected in 114 A.D., 53 feet in height, and consisting of a single arch of Parian marble of the Corinthian order, highly ornamented with basso and alto rilievos, which represent various events in the reign of that emperor. It now forms one of the gates of the city (*Porta Aurea*). Of the amphitheatre the remains, now known as *Grottoni di Mappa*, are in a very ruinous condition, and the arena is occupied by houses of a mean description. Benevento is the see of a bishop, and has a cathedral of the 12th century in the Lombardo-Saracenic style, in front of which is an Egyptian obelisk of granite covered with hieroglyphics. Among its other buildings may be mentioned the town-hall, the diocesan seminary, the lyceum, which was formerly a Jesuit college, and several hospitals. The principal manufactures are leather, parchment, and plated goods. A considerable trade is carried on in grain.

Beneventum, or, as it was originally called, Maloeis or Maleventum, seems to have been of Samnite foundation. In 268 B.C. it was colonized by the Romans, who had probably been in possession of it for some time. During the second Punic war two of the most important battles were fought in the neighbourhood. It continued to be a very flourishing city till the close of the empire, and from its position on the *Via Appia*, it often comes into notice. About 545 A.D. it was sacked by Totila, but before long had recovered its prosperity. Being raised to the rank of a duchy by Alboin, king of the Lombards, it continued in possession of its own dukes till 1053, when the emperor, Henry III., who had rendered himself master of the city, exchanged it with Leo IX. for the bishopric of Bamberg. From that time it continued in Papal possession till 1806, when the Emperor Napoleon I. bestowed it, with the title of prince, on Talleyrand.

BENGAL

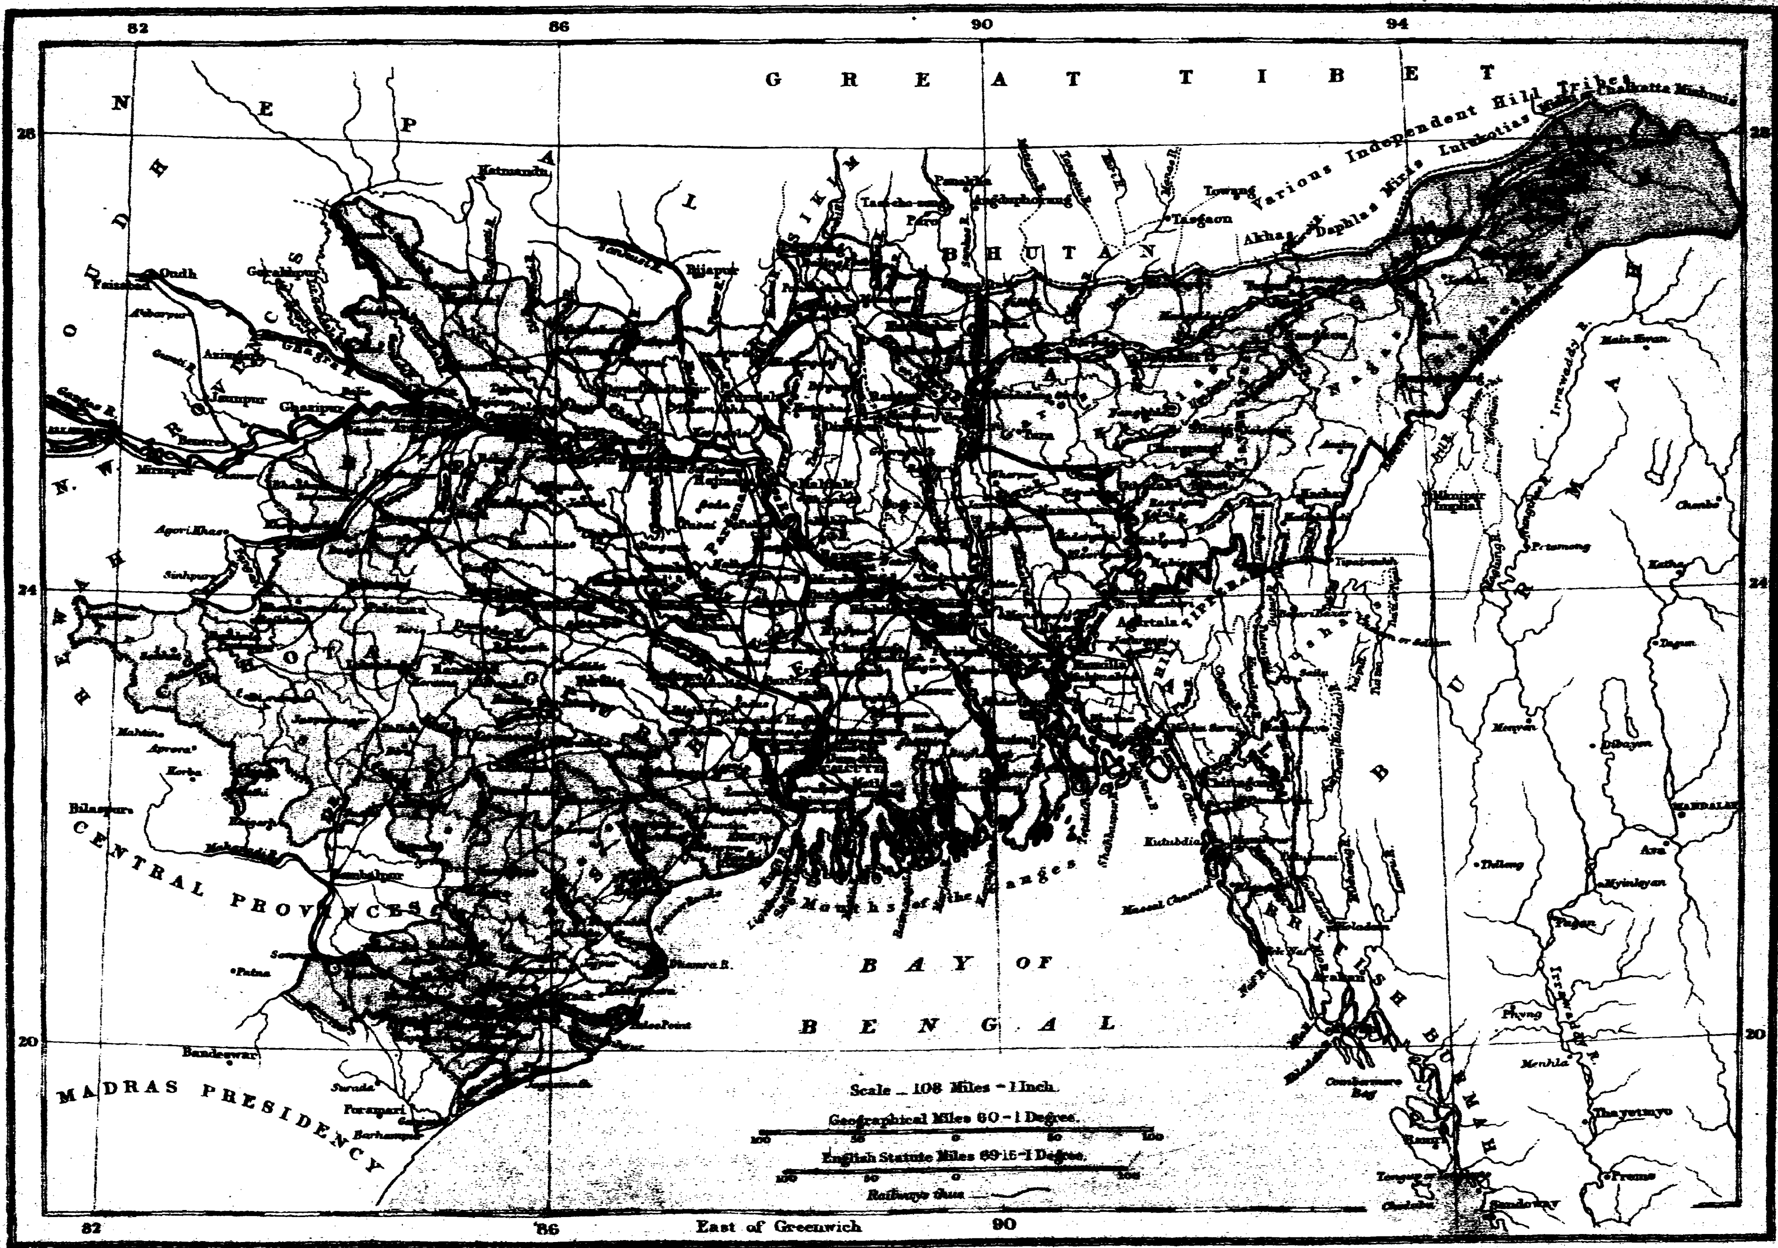
Plate IV.

BENGAL (or, as it is often more precisely designated, "Lower Bengal"), the largest and most populous of the twelve local governments of British India, comprising the lower valleys and deltas of the Ganges and Brahmaputra, lies between 19° 18′ and 28° 15′ N. lat., and between 82° and 97° E. long. Excluding Assam, which was erected into a separate administration in February 1874, Bengal new includes the four great provinces of Bengal Proper, Behar, Orissa, and Chhotá or Chutiá Nágpur; and forms a Lieutenant-Governorship with an area of 203,473 square miles, and a population of 61,444,379 souls. Including Assam, which, until the spring of 1874, was a part of Bengal, the area was 218,231 square miles, and the population 66,856,859. This great lieutenant-governorship, excluding Assam, contains one-third of the total population of British India, and yields a revenue of £17,687,072, or over one-third of the aggregate revenues of the Indian empire. It is bounded on the N. by Assam, Bhután, and Nepál; on the S. by Burmah, the Bay of Bengal, and Madras; on the W. by an imaginary line running between it and the adjoining lieutenant-governorship of the North-Western Provinces, and by the plateau of the Central Provinces; and on the E. by the unexplored mountainous region which separates it from China and Northern Burmah. The territory, thus hemmed in, except at its north-western angle, by the unchangeable land-marks of nature, consists chiefly of two broad river valleys. By the western one, the Ganges brings down the wealth and the accumulated waters of Northern India. The eastern valley forms the route by which the Brahmaputra, after draining the Thibetan plateau far to the north of the Himálayas, and skirting round their passes not far from the Yangtse-Kiang and the great river of Cambodia, ends its boisterous journey of 1800 miles. These valleys, although for the most part luxuriant alluvial plains, are diversified by spurs and peaks thrown out from the great mountain systems which wall them in on the north-east and south-west. They teem with every product of nature, from the fierce beasts and irrepressible vegetation of the tropics, to the stunted barley which the hill-man rears, and the tiny furred animal which he hunts within sight of the unmelting snows. Tea, indigo, turmeric, lac, waving white fields of the opium-poppy, wheat and innumerable grains and pulses, pepper, ginger, betel-nut, quinine and many costly spices and drugs, oil-seeds of sorts, cotton, the silk mulberry, inexhaustible crops of jute and other fibres; timber, from the feathery bamboo and coronetted palm to the iron-hearted *sál* tree—in short, every vegetable product which feeds and clothes a people, and enables it to trade with foreign nations, abounds. Nor is the country destitute of mineral wealth. The districts near the sea consist entirely of alluvial formations; and, indeed, it is stated that no substance so coarse as gravel occurs throughout the Delta, or in the heart of the provinces within 400 miles of the river mouths. But amid the hilly spurs and undulations on either side, coal, and iron and copper ores, hold out a new future to Bengal, as capital increases under the influence of a stable government, and our knowledge of the country becomes more exact. The coal-fields on the west have for exactly a century been worked by English enterprise; in 1868 they yielded 564,933 tons, and more in the two following years. In the east, the coal measures of Assam, which province was separated from Bengal in 1874, still await the opening out of the country and improved facilities of transport. The climate varies from the snowy regions of the Himálayas to the tropical vapour-bath of the Delta and the burning winds of Behar. The ordinary range of the thermometer on the plains is from about 52° Fahr. in the coldest month to 103° in the shade in summer. Anything below 60° is considered very cold; and by care in the hot weather the temperature of well-built houses rarely exceeds 95°. The rainfall also varies greatly; from 500 to 600 inches per annum at Chará Púnji (Cherra Poonjee) on the range between Silhet and Assam, to an average of about 37 inches in Behar, and about 65 inches on the Delta.

THE RIVERS.—But the secret of Bengal is its rivers. These untaxed highways bring down, almost by the motive power of their own current, the crops of Northern India to the sea-board,—an annual harvest of wealth to the trading classes, for which the population of the Lower Provinces neither toil nor spin. Lower Bengal, indeed, exhibits the two typical stages in the life of a great river. In the northern districts the rivers, like our English ones, run along the valleys, receive the drainage from the country on either side, absorb broad tributaries, and rush forward with an ever increasing volume. But near the centre of the provinces the rivers enter upon a new stage of their career. Their main channels bifurcate, and each new stream so created throws off its own set of distributaries to right and left. The country which they thus enclose and intersect forms the Delta of Bengal. Originally conquered by the fluvial deposits from the sea, it now stretches out as a vast dead level, in which the rivers find their velocity checked, and their current no longer able to carry along the silt which they have brought down from Northern India. The streams, accordingly, deposit their alluvial burden in their channels and upon their banks, so that by degrees their beds rise above the level of the surrounding country. In this way the rivers in the Delta slowly build themselves up into canals, which every autumn break through or overflow their margins, and leave their silt upon the adjacent flats. Thousands of square miles in Lower Bengal annually receive a top-dressing of virgin soil, brought free of expense a quarter of a year's journey from the Himálayas,—a system of natural manuring which renders elaborate tillage a mere waste of labour, and which defies the utmost power of over-cropping to exhaust its fertility. As the rivers creep further down the Delta, they become more and more sluggish, and their bifurcations and interlacings more complicated. The last scene of all is a vast amphibious wilderness of swamp and forest, amid whose solitudes their network of channels insensibly merges into the sea. Here the perennial struggle between earth and ocean goes on, and all the ancient secrets of land-making stand disclosed. The rivers, finally checked by the dead weight of the sea, deposit their remaining silt, which emerges as banks or blunted promontories, or, after a year's battling with the tide, adds a few feet or, it may be, a few inches to the foreshore.

The Ganges, which enters on the western frontier, and runs diagonally across Bengal, gives to the country its peculiar character and aspect. About 200 miles from its mouth it spreads out into numerous branches, forming a large delta, composed, where it borders on the sea, of a labyrinth of creeks and rivers, running through the dense forests of the Sundarbans, and exhibiting during the annual inundation the appearance of an immense sea. At this time the rice fields to the extent of many hundreds of square miles are submerged. The scene presents to a European eye a panorama of singular novelty and interest; —rice fields covered with water to a great depth; the

BENGAL AND ASSAM



ENCYCLOPÆDIA BRITANNICA, NINTH EDITION.

ears of grain floating on the surface; the stupendous embankments, which restrain, without altogether preventing, the excesses of the inundations; and peasants in all quarters going out to their daily work with their cattle in canoes or on rafts. The navigable streams which fall into the Ganges intersect the country in every direction, and afford great facilities for internal communication. In many parts boats can approach by means of lakes, rivulets, and water-courses, to the door of almost every cottage. The lower region of the Ganges is the richest and most productive portion of Bengal, abounding in valuable produce. Another mighty river by which Bengal is intersected is the Brahmaputra, the source of whose remotest tributary is on the opposite side of the same mountains which give rise to the Ganges. These two rivers proceed in diverging courses until they are more than 1200 miles asunder; and again approaching each other, intermix their waters before they reach the ocean. The other principal rivers in Bengal are the Ghagra, Son, Gandak, Kusi, Tistá; the Húglí (Hoogly), formed by the junction of the Bhágirathí and Jalangí; and farther to the west, the Damodar and Rúpnáráyan; and in the south-west, the Mahánadí, or great river of Orissa. In a level country like Bengal, where the soil is composed of yielding and loose materials, the courses of the rivers are continually shifting, from the wearing away of their different banks, or from the water being turned off by obstacles in its course into a different channel. As this channel is gradually widened the old bed of the river is left dry. The new channel into which the river flows is, of course, so much land lost, while the old bed constitutes an accession to the adjacent estates. Thus, one man's property is diminished, while that of another is enlarged or improved; and a distinct branch of jurisprudence has grown up, the particular province of which is the definition and regulation of the alluvial rights alike of private property and of the state.

The People.—Within the provinces under the Lieutenant-Governor of Bengal dwell a great congeries of peoples, of widely diverse origin, speaking different languages, and representing far separated eras of civilisation. They amounted in 1872 (including Assam, which then formed part of Bengal) to 66,856,859 souls, or over a million and a quarter more than the whole inhabitants of England and Wales, Sweden, Norway, Denmark (with Jutland), Greece, and all the Ionian Islands, with the total white population, Indians and Chinese, of the United States. The problem of government in Bengal, however, is not one of numbers. It is intensified and infinitely complicated by the fact, that while this vast population is ruled by a single head, it consists of elements so dissimilar as to render it impracticable to place them under any one system of administration. They exhibit every stage of human progress, and every type of human enlightenment and superstition,—from the sceptical educated classes, represented by the Hindu gentleman who distinguishes himself at a London Inn of Court and harangues the British public in the Brighton Pavilion, or from a metropolitan platform, to the hill chieftain, who lately sacrificed an idiot on the top of a mountain to obtain a favourable decision in a Privy Council appeal. A large section of the people belongs to the august Aryan race, from which we ourselves descend, having a classical language more kindred to our own than those of the Welsh or Scottish Highlanders. We address the Deity and His earthly representatives, our father and mother, by words derived from roots common to the Christian and the Hindu. Nor does the religious instinct assume a wider variety of manifestations, or exhibit a more striking series of metamorphoses, among the European than among the Indian branches of the race. Theodore Parker and Comte are better known to the rising generation of Hindus in Bengal than any Sanskrit theologian. On the same bench of a Calcutta college sit youths trained up in the strictest theism, others indoctrinated in the mysteries of the Hindu trinity and pantheon, with representatives of every link in the chain of superstition—from the harmless offering of flowers before the family god to the cruel rites of Kálí, whose altars in the most civilised districts of Bengal, as lately as the famine of 1866, were stained with human blood. Indeed, the very word Hindu is one of absolutely indeterminate meaning. The census officers employ it as a convenient generic to include $42\frac{1}{2}$ millions of the population of Bengal, comprising elements of transparently distinct ethnical origin, and separated from each other by their language, customs, and religious rites. But Hinduism, understood even in this wide sense, represents only one of many creeds and races found within Bengal. The other great historical cultus, which, during the last twelve centuries, did for the Semitic peoples what Christianity accomplished among the European Aryans, has won to itself one-third of the whole population of Bengal. The Muhammadans exceed $20\frac{1}{2}$ millions of souls; and the Lieutenant-Governor of Bengal is, so far as numbers go, as great a Musalmán power as the Sultán of Turkey himself. Amid the stupendous catastrophes of the seasons, the river inundations, famines, tidal waves, and cyclones of the lower provinces of Bengal, the religious instinct works with a vitality unknown in European countries, where the forces of nature have long yielded to the control of man. Until the British Government stepped in with its police, and canals, and railroads, between the people and what they were accustomed to consider the dealings of Providence, scarcely a year passed without some terrible manifestation of the power and the wrath of God. Marhattá invasions from Central India, piratical devastations on the sea-board, banditti who marched about the interior in bodies of 50,000 men, floods which drowned the harvests of whole districts, and droughts in which a third of the population starved to death, kept alive a sense of human powerlessness in the presence of an Omnipotent fate with an intensity which the homilies of a stipendiary clergy fail to awaken. Under the Muhammadans a pestilence turned the capital into a silent wilderness, never again to be re-peopled. Under our own rule, it is estimated that 10 millions perished within the Lower Provinces alone in the famine of 1769–70; and the first surveyor-general of Bengal entered on his maps a tract of many hundreds of square miles as bare of villages, and "depopulated by the Maghs."

Popular Religions.—The people of Bengal, thus constantly reminded by calamity of a mysterious Supreme Power, have always exhibited deep earnestness in their own modes of propitiating it, and a singular susceptibility to new forms of faith. Great tidal waves of religion have again and again swept over the provinces within even the brief period of the Christian era. Islám was one of many reformed creeds offered to them, and several circumstances combined to render its influence more widely spread and more permanent than that of its rivals. It was the creed of the governing power; its missionaries were men of zeal, who spoke to the popular heart; it brought the good news of the unity of God and the equality of man to a priest-ridden and a caste-ridden people. Above all, the initiatory rite made relapse impossible, and rendered the convert and his posterity true believers for ever. Forcible conversions are occasionally recorded, with several well-known instances of Hindus becoming apostates from their ancient faith to purchase pardon for crimes. Such cases, however, were few in number, and belonged to the higher ranks. It would also appear that a Mughul adventurer now and then

circumcised off hand the villages allotted to him in fief. But it was not to such measures that Islám owed its permanent success in Bengal. It appealed to the people, and it derived the great mass of its converts from among the poor. It brought in a truer conception of God, a nobler ideal of the life of man, and offered to the teeming low castes of Bengal, who had sat for ages despised and abject on the outermost pale of the Hindu community, free entrance into a new social organisation. So far as local tradition and the other fragmentary evidence which survives enable a modern inquirer to judge, the creed of Muhammad was here spread neither by violence nor by any ignoble means. It succeeded because it deserved to succeed. Nevertheless, it has conspicuously failed to alter the permanent religious conceptions of the people. The initiatory rite separated the Musalmáns from the rest of the Bengali population, and elevated the heterogeneous low-caste converts into a respectable community of their own. But the proselytes brought their old superstitions with them into their new faith. Their ancient rites and modes of religious thought reasserted themselves with an intensity that could not be suppressed, until the fierce white light of Semitic monotheism almost flickered out amid the fuliginous exhalations of Hinduism. A local writer, speaking from personal acquaintance with the Musalmán peasantry in the northern districts of Lower Bengal, states that not one in ten can recite the brief and simple *kalmá* or creed, whose constant repetition is a matter of almost unconscious habit with Muhammadans. He describes them as "a sect which observes none of the ceremonies of its faith, which is ignorant of the simplest formulas of its creed, which worships at the shrines of a rival religion, and tenaciously adheres to practices which were denounced as the foulest abominations by its founder." Fifty years ago these sentences would have truly described the Muhammadan peasantry, not only in the northern districts, but throughout all Lower Bengal. In the cities, or amid the serene palace life of the Musalmán nobility and their religious foundations, a few Maulvís of piety and learning calmly carried on the routine of their faith. But the masses of the rural Musalmáns had relapsed into something little better than a mongrel breed of circumcised low-caste Hindus. Since then, one of those religious awakenings so characteristic of India has passed over the Muhammadans of Bengal. Itinerant preachers, generally from the north, have wandered from district to district, calling on the people to return to the true faith, and denouncing God's wrath on the indifferent and unrepentant. A great body of the Bengali Musalmáns have purged themselves of the taint of Hinduism, and shaken off the yoke of ancient rural rites. The revival has had a threefold effect—religious, social, and political. It has stimulated the religious instinct among an impressionable people, and produced an earnest desire to cleanse the worship of God and His prophet from idolatry. This stern rejection of ancient superstitions has widened the gulf between the Muhammadans and the Hindus. Fifty years ago the Bengali Musalmáns were simply a recognised caste, less widely separated from the lower orders of the Hindus than the latter were from the Kulin Bráhmans. There were certain essential points of difference, of a doctrinal sort, between the Hindu and Muhammadan villager; but they had a great many rural customs and even religious rites in common. The Muhammadan husbandman theoretically recognised the one Semitic God; but in a country subject to floods, famines, the devastations of banditti, and the ravages of wild beasts, he would have deemed it a simple policy to have neglected the Hindu festivals in honour of Krishna and Durgá. The Bengali peasantry no longer look to their gods, but to the officer in charge of the district, for protection; and when he fails them, instead of offering expiatory sacrifices to Káli, they petition Government, or write violent letters to the vernacular press. The reformed Muhammadan husbandmen now stand aloof from the village rites of the Hindus. They have ceased to be merely a separate caste in the rural organisation, and have become a distinct community, keeping as much apart from their nominal co-religionists of the old unreformed faith as from the idolatrous Hindus. This social isolation from the surrounding Hindus is the second effect of the Musalmán revival in Bengal. Its third result is political, and affects ourselves. A Muhammadan like a Christian revival strongly reasserts the duty of self-abnegation, and places a multitude of devoted instruments at the disposal of any man who can convince them that his schemes are identical with the will of God. But while a return to the primitive teachings of Christ means a return to a religion of humanity and love, a return to Muhammadan first principles means a return to a religion of intolerance and aggression. The very essence of Musalmán Puritanism is abhorrence of the Infidel. The whole conception of Islám is that of a church either actively militant or conclusively triumphant—forcibly converting the world, or ruling with a rod of iron the stiff-necked unbeliever. The actual state of India, where it is the Musalmáns who are in subjection, and the unbeliever who governs them, is manifestly not in accord with the primitive ideal; and many devout Muhammadans of the reformed faith have of late years endeavoured, by plots and frontier attacks, to remove this anomaly. The majority are not actively hostile, but they stand aloof from our institutions, and refuse to coalesce with the system which the British Government has imposed on Bengal. Their rebel camp beyond our frontier has forced us into three expeditions, which has broken their military power; and the calm, inexorable action of the courts has stamped out the chronic abetment of rebellion by Muhammadans within Bengal.

Besides the $42\frac{1}{2}$ millions aggregated under the name of Hindus, and the $20\frac{1}{2}$ millions of Musalmáns, a great residue remains. These consist, with the exception of two very small bodies of Christians and Buddhists, of semi-aboriginal and distinctly non-Aryan races. They number over $3\frac{1}{2}$ millions, equalling almost exactly the population of Scotland. These peoples dwell, for the most part, among the lofty ranges and primeval forests which wall in Bengal on the north, east, and south-west, or upon the spurs and hilly outworks which these mountain systems have thrown forward upon the lowlands. Some of them represent the simplest types of social organisation known to modern research. Their rudimentary communities are separated by religion, custom, and language from each other and from the dwellers on the plains. Many of them, till lately, looked upon war as the normal condition of human society, and on peace as an unwelcome temporary break in their existence. For ages they have regarded the lowland Hindus as their natural enemies, and in turn have been dealt with as beasts of chase by the more civilised inhabitants of the valleys. Within the present generation human sacrifice continued to be an obligatory rite among them—a rite so deeply graven upon their village institutions, and so essential to the annually recurring festivals of their religious year, as to seriously occupy the Indian legislature, and to require a special agency to suppress it. To this day instances of the detestable practice occur; and their extreme jealousy of anything like foreign rule renders it the wisest policy to leave them as much as possible under their own hamlet communities and petty chiefs. Nevertheless, they form the most hopeful material yet discovered in Bengal for the humanising influences of Christianity, and of that higher level of

morality and religious hope which Christian missions represent.

GOVERNMENT.—Nor are the diversities in race and religion among the 66$\frac{3}{4}$ millions of Bengal less marked than their different capacities for self-government, and the varying degrees to which they can be subjected to administrative control. They exhibit every stage of political development, from the great municipality based upon English models, with powers of self-taxation and a public debt of its own, down to the primitive hill-hamlet, which pays no rent, acknowledges no higher tenure than the aboriginal one of priority of occupation, clings to its ancient system of nomadic husbandry, and is scarcely aware of any power superior to that of its own tribe fathers. Including Assam, which up to February 1874 formed a part of Bengal, the territories under the Lieutenant-Governor consist of five great provinces, each of which speaks a language of its own, and has a separate political and ethnical history. For administrative purposes these five provinces are divided into 58 districts, of which 36 are regulation districts, whose advanced state has rendered it expedient to place them under the complete system of Anglo-Indian law; while 22 are non-regulation districts, in which this has not yet been found practicable. The latter contain territories of three distinct classes. The first of them consists, for the most part, of newly-acquired territory, to which the general regulations have never been extended in their entirety. The second, of tracts inhabited by primitive races specially exempted from the operation of the regulations, to whom a less formal code of law is better adapted. The third, of semi-independent or tributary states, administered, or partly administered by British officers. The management of the whole is firmly concentrated in a single man, the Lieutenant-Governor of Bengal, who is answerable to the Government of India, and through it to Her Majesty's ministers and Parliament. His responsibility is divided by no executive council, as in Madras or Bombay. All orders issue through his secretaries in his own name; and although his policy is subject to the watchful control of the Government of India, represented by the Viceroy, yet to the Lieutenant-Governor personally belongs the reputation or disgrace of a successful or an inglorious administration. In making laws for his people he is assisted by a legislative council, composed partly of his principal officers, partly of leading members of the non-official European and Native communities. In his legislative, as in his executive functions, a power of control, amounting if needful to veto, rests with the Government of India—a power which, from the English talent for harmonious proconsular rule, is very seldom exercised. The administration is conducted by a body of covenanted civilians, supplemented by a few military officers in the less civilised districts, and aided by a staff of subordinate officials. The civilians are appointed direct from England, enter into a bond with the Secretary of State, and give securities for the discharge of their highly responsible duties. In 1871 they numbered 260 men. The military officers belong to the staff corps of the Bengal army, and are employed to the number of 52 in the backward tracts, which do not require so exact an administration, and cannot afford to pay for the cost of it. The subordinate district officials are appointed in Bengal by the Lieutenant-Governor, and consist chiefly of natives and Anglo-Indians; but several departments, such as the educational, telegraph, and public works, are now officered to a certain extent by gentlemen engaged direct from England. The revenues raised in the territories under the Lieutenant-Governor of Bengal amounted in 1871–72 to £17,687,072. Of this sum, £16,713,636 accrued from the imperial taxes laid on by the Government of India, and £973,436, from provincial, municipal, and rural taxation. The total cost of government was only £6,338,968, leaving a surplus from this single one of the Indian local governments of £11,348,104. It is scarcely too much to say, that so long as the British power retains the port of Calcutta and the rich provinces under the Lieutenant-Governor of Bengal, it would have sufficient revenue to effect the reconquest of India if any accident should happen in the Panjáb or north-west. The vast income which the Lower Provinces yield is not altogether derived from their people. China pays an annual tribute of over 5 millions in the shape of opium duty, and the inland parts of India contribute about a third of a million to the customs of Bengal. Taking the total thus obtained from other territories at a little over 6 millions, the population under the Lieutenant-Governor of Bengal pays, in round figures, 11$\frac{1}{2}$ millions a year, or about 3s. 5d. a head. This includes imperial, provincial, municipal, and rural taxation of every sort.

The return which the Government gives for this light taxation may be briefly summed up as follows:—It assures to the provinces absolute protection from foreign enemies. The army employed in the territories under the Lieutenant-Governor of Bengal numbers only 11,554 officers and men, exclusive of a detachment of Madras Native infantry stationed at Cattack, in Orissa, and numbering about 600 men making a gross total of troops in Bengal of about 12,000 men. Of this small force 4662 are massed in Calcutta and its environs, with a view to their proximity to the sea-board, rather than with an eye to the internal requirements of the country; 6892 guard the frontiers, with detachments on the line of railway, which now forms the great highway of Bengal; a detachment of about 600 effective troops of the Madras Native infantry is stationed in Orissa. Taking 12,000 as the total military force stationed in Bengal, 3000 consist of European troops and English officers, and 9000 of Native officers and men. The Government is a purely civil one, the existence of any armed force being less realised than in the quietest county of England; and of the 66$\frac{3}{4}$ millions of people under the Lieutenant-Governor of Bengal, probably 40 millions go through life without once seeing the gleam of a bayonet or the face of a soldier. Internal order and protection to person and property are secured by a large army of police. This force consists of two elements: a regular constabulary introduced by the English Government, numbering 33,913 men in 1871, and costing £584,059 to the state; and an indigenous police developed out of the rural watch of the ancient Hindu commonwealth, numbering 184,645 men, and costing £435,336 a year, paid by grants of land, or by the villages and landowners. The total number of the Bengal police amounts therefore to 217,558, or one man to every 307 of the population; and, excluding uninhabited swamps and hill jungles, about one policeman to each square mile of area. This minute supervision costs just over a million sterling a year, being at the rate of £4, 2s. 1$\frac{1}{2}$d. per square mile, or 3$\frac{1}{2}$d. per head of the population.

A great system of state education has been rapidly developed since 1854. In 1871–72 the Government and aided schools numbered 4383, with 7292 teachers, and 163,280 pupils,—maintained at a total cost of £194,716, of which Government contributed rather under one-half, or £89,649. The total annual cost of education per pupil was £1, 12s. 9d., of which Government bore under one-half, or 15s.; the remainder being obtained from school fees, local subscriptions, &c. Besides these, there were 10,907 ascertained schools not receiving aid from the state, with 11,026 teachers, and 169,917 pupils. In addition to these, there is a vast number of petty hedge schools in Bengal, of which no statistics exist. The total of state and *ascertained*

private schools in 1871, was 15,290, with 18,318 teachers, and 333,197 pupils.

The cheapness of labour, as compared with European countries, enables the Government to perform its other functions at an equally small cost. It has brought courts very near to the door of the peasant, and established a system of registration by which proprietary rights and transfers are cheaply and absolutely ascertained. A great department of public works has spread a network of roads over the country, connecting Bengal by railways with other parts of India, and, in districts which specially require it, is endeavouring to exercise some degree of control over the rivers and the natural water-supply, on which the safety of a tropical people depends. An organised system of emigration watches over the movements of the landless classes, from the overcrowded or unfertile districts of the west to the rich under-populated territories on the east, and to colonies beyond the seas. Charitable dispensaries and a well-equipped medical department struggle to combat the diseases and epidemics which from time immemorial have devastated the Delta, and place the operations of European surgery within the reach of the poorest peasant. The whole cost of civil administration for the 66¾ millions of Bengal amounts, as already stated, to £6,338,968, or under 1s. 11d. per head. An unfettered vernacular press makes known the views of the people to their rulers, and municipal institutions are developing the ancient Hindu capacity for self-government from the village to the municipal stage of human society.

Local Divisions.—The following table exhibits the four provinces at present under the Lieutenant-Governor of Bengal, along with Assam, which until February 1874 was within it.

Area, Population, and Languages of the Five Provinces of Lower Bengal (including Assam) in 1872.

Provinces.	Area in square miles.	Population.	Average population per sq. mile.	Percentage of entire area.	Percentage of the whole population	Languages.
Bengal, ...	94,539	36,769,735	389	38·08	55·00	Bengali and Hindustání.
Behar, ...	42,417	19,736,101	465	17·09	29·52	Hindustání and Hindí.
Orissa (including the Tributary States),	23,901	4,317,999	181	9·63	6·46	Uriyá, and aboriginal tongues and patois.
Chhotá Nágpur, ...	43,901	3,825,571	87	17·69	5·72	Bengali and aboriginal tongues.
Assam (separated in 1874), ...	43,473	2,207,453	51	17·51	3·30	Assamese, Bengali, and aboriginal tongues
Total,......	248,231	66,856,859	269	100·00	100·00	

The word Bengal is derived from Sanskrit geography, and applies strictly to the country stretching southwards from Bhagalpur to the sea. The ancient Banga formed one of the five outlying kingdoms of Aryan India, and was practically conterminous with the Delta of Bengal. It derived its name, according to the etymology of the Pandits, from a prince of the Mahábhárata, to whose portion it fell on the primitive partition of the country among the Lunar race of Delhi. But a city called Bángálá, near Chittagong, which, although now washed away, is supposed to have existed in the Muhammadan period, appears to have given the name to the European world. The word Bángálá was first used by the Musalmáns; and under their rule, like the Banga of old Sanskrit times, it applied specifically to the Gangetic delta, although the latter conquests to the east of the Brahmaputra were eventually included within it. In their distribution of the country for fiscal purposes, it formed the central province of a governorship, with Behar on the N.W., and Orissa on the S.W., jointly ruled by one deputy of the Delhi emperor. Under the English the name has at different periods borne very different significations. Francis Fernandez applies it to the country from the extreme east of Chittagong to Point Palmyras in Orissa, with a coast line which Purchas estimates at 600 miles, running inland for the same distance, and watered by the Ganges. This territory would include the Muhammadan province of Bengal, with parts of Behar and Orissa. The loose idea thus derived from old voyagers became stereotyped in the archives of the East India Company. All its north-eastern factories, from Balasor, on the Orissa coast, to Patná, in the heart of Behar, belonged to the "Bengal Establishment," and as our conquests crept higher up the rivers, the term came to be applied to the whole of Northern India. The Presidency of Bengal, in contradistinction to those of Madras and Bombay, eventually included all the British territories north of the Central Provinces, from the mouths of the Ganges and Brahmaputra to the Himálayas and the Panjáb. The term Bengal continues to be officially employed in this sense by the military department of the Government of India. But during the last forty years the tendency to a more exact order of civil administration has gradually brought about a corresponding precision in the use of Indian geographical names. The North-Western Provinces date their separate existence from 1831. Since that year they stand forward under a name of their own as the North-Western Provinces, in contradistinction to the Lower Provinces of Bengal. Later annexations have added new territorial entities, and the northern Presidency is now mapped out into four separate governments—the North-Western Provinces, Oudh, Panjáb, and Lower Bengal. Three of the provinces of the present Lieutenant-Governorship of Bengal—namely, Bengal proper, Behar, and Orissa—consist of great river valleys; the fourth, Chhotá or Chutiá Nágpur, is a mountainous region which separates them from the Central India plateau. Orissa embraces the rich deltas of the Mahánadí and the neighbouring rivers, bounded by the Bay of Bengal on the S.E., and walled in on the N.W. by tributary hill states. Proceeding westward, the province of Bengal proper stretches along the coast from Orissa to British Burmah, and inland from the sea-board to the Himálayas. Its southern portion is formed by the united deltas of the Ganges and Brahmaputra; its northern consists of the valleys of these great rivers and their tributaries. Behar lies on the north-west of Bengal proper, and comprises the higher valley of the Ganges, from the spot where it issues from the territories of the Lieutenant-Governor of the North-Western Provinces. Between Behar and Orissa, but stretching further westward and deep into the hill country, lies the province of Chhotá or Chutiá Nágpur.

Administrative Divisions.—For administrative purposes, the Lieutenant-Governorship of Bengal, excluding the recently separated province of Assam (see under that heading), is divided into 47 districts. The details of the area and population of these, presented in the following table, are taken, with few exceptions, from the census returns of 1872:—

District.	Area—square miles.	Population.	Hindus.	Muhammadans.	Christians	Others.	Population per square mile.	Land Revenue.
BENGAL PROPER								
1. Bardwán,	3,523	2,034,745	1,679,363	348,024	890	6,468	578	£306,454

[1] The census of the Duárs of Jalpaigurí was taken in 1869–70, at the time of the land settlement, and the details of the population, according to religion, were not ascertained for this part of the district. The details, therefore, do not agree with the total population.

[2] Census taken at the time of settlement. Details not ascertained.

[3] This area is exclusive of 5341 square miles of unsurveyed Sundarbans, and one or two minor tracts; total area of all Bengal, 203,473 square miles.

PRINCIPAL CROPS.—The chief products of the province have been already enumerated. The great staple crop is rice, of which there are three harvests in the year,—the *boro*, or spring rice; *áus*, or autumn rice; and *áman*, or winter rice. Of these the last or winter rice is by far the most extensively cultivated, and forms the great harvest of the year. The *áman* crop is grown on low land. In May, after the first fall of rain, a nursery ground is ploughed three times, and the seed scattered broadcast. When the seedlings make their appearance another field is prepared for transplanting. By this time the rainy season has thoroughly set in, and the field is dammed up so as to retain the water. It is then repeatedly ploughed until the water becomes worked into the soil, and the whole reduced to thick mud. The young rice is then taken from the nursery, and transplanted in rows about 9 inches apart. If, by reason of the backwardness of the season, the nursery ground cannot be prepared by the sowing-time in April or May, the áman rice is not transplanted at all. In such a case the husbandmen in July or August soak the paddy in water for one day to germinate, and plant the germinated seed not in a nursery plot, but in the larger fields, which they would otherwise have used to transplant the sprouts into. It is very seldom, however, that this procedure is found necessary. *Áman* rice is much more extensively cultivated than *áus*, and in favourable years is the most valuable crop, but being sown in low lands is liable to be destroyed by excessive rainfall. Harvest takes place in December or January. *Aus* rice is generally sown on high ground. The field is ploughed when the early rains set in, ten or twelve times over, till the soil is reduced nearly to dust, the seed being sown broadcast in April or May. As soon as the young plants reach 6 inches in height, the land is harrowed for the purpose of thinning the crop and to clear it of weeds. The crop is harvested in August or September. *Boro*, or spring rice, is cultivated on low marshy land, being sown in a nursery in October, transplanted a month later, and harvested in March and April. An indigenous description of rice, called *uri* or *jaradhán*, grows in certain marshy tracts. The grain is very small, and is gathered for consumption only by the poorest. No tabulated statistics of cultivation exist; but in 1872-73 the quantity of rice exported from Bengal to foreign ports amounted to 288,955 tons, of the value of £1,685,170. Oil-seeds are very largely grown over the whole of Bengal, particularly in the Behar and Assam districts. The principal oil-seeds are *sarisha* (mustard), *til* (sesamum), and *tisi*, or *masina* (linseed). Exports of oil-seeds are principally confined to linseed, of which 107,723 tons were exported in 1872–73, of the value of £1,077,318. Jute (*pat* or *kosta*) now forms a very important commercial staple of Bengal. The cultivation of this crop has rapidly increased of late years. Its principal seat of cultivation is Eastern Bengal, where the superior varieties are grown. The crop grows on either high or low lands, is sown in April, and cut in August. In 1872 the area under jute cultivation in Bengal was estimated at 925,899 acres, and the yield at 496,703 tons. Jute exports from Bengal amounted in 1872-73 to 353,097 tons, value £4,127,943. Jute manufactures in the shape of gunny bags, cloth, rope, &c., were also exported to the value of £187,149. Indigo cultivation and manufacture is principally carried on with European capital. In Bengal proper the industry has languished of late years, and the area under indigo cultivation greatly fallen off. In Behar, on the other hand, the area of indigo lands has increased. The annual out-turn for all Bengal is estimated at about 75,000 maunds, valued at nearly two millions sterling. Two crops of indigo are raised in the year: one sown in April or May before the setting in of the rains, and cut in August or September; the other sown in October as the waters subside, and cut in the following July. The crop of 1872 was considerably above the average, the total exports amounting to 5962 tons, of the value of £2,704,080. Tea cultivation is the other great industry carried on by European capital. The cultivation is principally confined to Assam, which province was recently separated from the Lieutenant-Governorship, and to the northern Bengal district of Dárjiling. In the other localities in which tea is grown, Chhotá Nágpur and Chittagong, cultivation is at present only carried on on a small scale. Tea cultivation has enormously extended of late years, and the gardens are, as a general rule, well filled with plants, highly cultivated and carefully managed. Including Assam, the total area held under the Waste Land Rules by persons connected with the tea industry, amounted in 1872 to 804,582 acres. Of this area 70,341 acres are returned as actually cultivated with tea, but this is probably too low an estimate. The exports of tea in 1872–73 amounted to 17,641,070 lb, valued at £1,567,561. Besides what is exported, there is an increasing local consumption of Indian tea. In 1860 the total out-turn of tea did not exceed one million lb. The cultivation of opium is a Government monopoly; no person is allowed to grow the poppy except on account of the Government. The manufacture is carried on at two separate agencies,—that of Benares in the North-Western Provinces, of which the head station is at Gházipur; and that of Behar, with its head station at Patná. Annual engagements are entered into by the cultivators, under a system of pecuniary advances, to sow a certain quantity of land with poppy, and the whole produce in the form of opium is delivered to Government at a fixed rate. The area under poppy cultivation in the Behar agency, situated entirely within Bengal, in 1872, amounted to 330,925 acres; in the Benares agency to 229,430 acres, total, 560,355 acres. The number of chests of opium sold at the Government sales in Calcutta in 1872, was 42,675, the amount realised was £6,067,701, and the net revenue, £4,259,376. The cultivation of the cinchona plant in Bengal was introduced as an experiment about 1862, in a valley of the Himálayas in Dárjiling district, and the enterprise has already attained a point which promises success. There are now (1874) about 2000 acres of Government cinchona plantations in Dárjiling.

MINERAL PRODUCTS.—A brief statement has already been given of the principal minerals of Bengal. The coal mines of Ráníganj, within Bardwán district, however, demand somewhat more special notice. In this field there were, in 1872, altogether 44 mines worked, of which 19 turn out more than 10,000 tons of coal per annum apiece. In the larger and better mines, coal is raised by steam power from pits and galleries; and in the smaller mines or workings, by hand labour from open quarries. In the Ráníganj coal-field alone, 61 steam engines, with an aggregate of 867 horse-power, are at work. Only one seam or set of seams of less thickness than 8½ feet is worked, and the average thickness of the seams at the Ránígani mines is about 15 or 16 feet. The pits are mostly shallow, very few are more than 150 feet deep. The Bengal Coal Company, with its mines at Ráníganj and westwards, is able to raise from them 220,000 tons of coal annually. Salt manufacture was formerly a Government monopoly, principally carried on along the sea-coast of Orissa and in Midnapur district. An account of the manufacture of salt by means of evaporation by fire is given in the account of BALASOR (*q.v.*) The process of manufacture by means of solar evaporation will be described in the account of PURÍ district. Government abandoned its monopoly of salt manufacture many years ago, and it is now carried on by private parties on their own account, subject to a Government duty in Bengal of 8s. 8d. a cwt. levied at the place of production. Salt duties

vary in different parts of India, necessitating the maintenance of expensive and cumbrous customs lines. This year (1874) an attempt has been made towards the abolition of the Orissa customs line, by means of a graduated scale of salt duty within Orissa, rising by degrees from the Madras duty of 4s. 10d. a cwt. in the extreme south of the province, to the Bengal duty of 8s. 8d. a cwt. in the extreme north. At the present day the greater quantity of salt consumed in Bengal is imported by Liverpool ships from the Cheshire mines. In 1872 the Bengal salt duty yielded a net revenue of £2,610,286.

Trade.—No complete statistics of the internal trade of Bengal exist. The Ganges, the Brahmaputra, and on a much smaller scale, the Mahánadí in Orissa, with the Eastern Bengal Railway and the great East Indian Line, form the main arteries of commerce. From these main channels a network of minor streams, and a fairly adequate although not yet complete system of raised roads, radiate to the remotest districts. The chief articles of internal traffic are the vegetable and mineral productions enumerated above. The larger transactions of commerce are conducted in the great cities, such as Calcutta and Patná, and in a number of purely market centres, such as Nawábganj and Sirájganj, which have recently grown up under British rule. The smaller operations of trade are effected by means of village markets and countless *háts* or open air weekly bazárs in every district. The external trade of Bengal is practically confined to Calcutta. There are about ten other ports on the Bay of Bengal, the most important of which is the rice port of Chittagong. But for general purposes the foreign and interportal commerce of Calcutta may be taken to represent that of the province. In 1871–72 it stood thus: exports from Calcutta, £32,771,152; imports, £21,365,677; total, £54,136,829. The chief articles of export are rice, opium, indigo, jute, tea, oil-seeds, silk, cotton, and fibres. Chief imports, Manchester goods, woollens, salt, coal, iron, metals, liquors, and oilmen's stores.

History.—The history of so large a province as Bengal forms an integral part of the general history of India. (See India.) The northern part, Behar, formed a powerful kingdom in Sanskrit times, and its chief town, Patná, is identified as the *Palibothra* of the Greeks. The Delta or southern part of Bengal lay beyond the ancient Sanskrit polity, and was governed by a number of local kings belonging to a pre-Aryan stock. The Chinese travellers, Fa Hiang in the 5th century, and Hiouen Thsang in the 7th century, found the Buddhist religion prevailing throughout Bengal, but already in a fierce struggle with Hinduism—a struggle which ended about the 9th or 10th century in the general establishment of the latter faith. Until the end of the 12th century Hindu princes governed in a number of petty principalities, till, in 1199, Muhammad Bakhtiyar Khilji was appointed to lead the first Musalmán invasion into Bengal. The Muhammadan conquest of Behar dates from 1200 A.D., and the new power speedily spread southwards into the Delta. From about this date until 1340 Bengal was ruled by governors appointed by the Muhammadan emperors in the north. From 1340 to 1539 its governors asserted a precarious independence, and arrogated the position of sovereigns on their own account. From 1540 to 1576 Bengal passed under the rule of the Pathán or Afghán dynasty, which commonly bears the name of Sher Sháh. On the overthrow of this house by the powerful arms of Akbar, Bengal was incorporated into the Mughul empire, and administered by governors appointed by the Dehli emperor, until the treaties of 1765, which placed Bengal, Behar, and Orissa under the administration of the East India Company. Until 1854 Bengal remained under the Governor-General of India as governor, his place being supplied, during his absence in other parts of India, by a deputy-governor from among the members of his council. By the statute 16 and 17 Vict. cap. 95, these two great offices were separated, and Bengal erected into a Lieutenant-Governorship. The first lieutenant-governor was appointed in 1854, and the constitution of the Government of Bengal still continues on this basis, except that the lieutenant-governor is now appointed subject to the approval of Her Majesty. In a brief sketch like the present it is impossible to attempt further historical details beyond a bare list of the successive rulers, and the dates of their accession.

First Period.

Early Muhammadan Conquerors of Bengal.

A.D.	A.H.	Governors of Bengal.	Emperors of Hindustan.	Kings of England.
1204	600	Bakhtiyar Khilji	Kutab	John
1206	602	Muhammad Sherán	Do.	Do.
1208	605	Alí Mardán	Do.	Do.
1212	609	Ghyas Uddín	Altamsh	Do.
1227	624	Nasír Uddín	Do.	Henry III.
1230	627	Alá Uddín	Do.	Do.
1237	634	Tughan Khán	Sultáná Riziá	Do.
1244	642	Taimur Khán	Bahram II.	Do.
1246	641	Saif Uddín	Nasír Uddín Muhammad	Do.
1253	651	Mulk Uzbek	Do.	Do.
1257	656	Jalál Uddín	Do.	Do
1258	657	Irsilan Khán	Do.	Do.
1260	659	Tatar Khán	Do.	Do.
1277	676	Tughral Khán	Balin	Edward I.
1282	681	Nasír Uddín	Do.	Do.
1325	725	Kadr Khán	Muhammad III.	Edward II.

Second Period.

Independent Muhammadan Kings of Bengal.

1340	741	Fakir Uddín	Muhammad III.	Edward III.
1343	743	Ilyas Sháh	Do.	Do.
1358	760	Sikandar Sháh	Firuz III.	Do.
1367	769	Ghiyas Uddín II.	Do.	Do.

1739	1151	Sarfaraz Khán	Do.	Do.
1740	1153	Alí Vardí Khán	Do.	Do.
1756	1170	Siráj Ud Daulá	Alamgír	Do.

The above chronology is taken from Stewart's *History of Bengal.*

FIFTH PERIOD.

Governors of Bengal and Governors-General of India under the East India Company, 1765–1854.

1765, Lord Clive; 1767, Harry Verelst; 1769, John Cartier; 1772, Warren Hastings; 1785, Sir John Macpherson; 1786, Marquis Cornwallis; 1793, Sir John Shore (Lord Teignmouth); 1798, Sir Alured Clarke (*pro. tem.*); 1798, Marquis Wellesley; 1805, Marquis Cornwallis; 1806, Earl of Minto; 1813, Marquis of Hastings; 1823, John Adam (*pro. tem.*); 1823, Earl Amherst; 1828, Lord William Cavendish Bentinck; 1835, Sir Charles Metcalf; 1836, Earl Auckland; 1842, Earl of Ellenborough; 1844, Viscount Hardinge; 1848, Marquis of Dalhousie.

SIXTH PERIOD.

Bengal under Lieutenant-Governors, 1854–1874.

Sir Frederic Halliday; Sir John Peter Grant; Sir Cecil Beadon; Sir William Grey; Sir George Campbell; Sir Richard Temple.

English connection with Bengal.—The East India Company formed its earliest settlements in Bengal in the first half of the 17th century. These settlements were of a purely commercial character. In 1620 one of the Company's factors dates from Patná; in 1624–36 the Company established itself, by the favour of the emperor, on the ruins of the ancient Portuguese settlement of Pípli, in the north of Orissa; in 1640–42 the patriotism of an English surgeon, Mr Gabriel Boughton, obtained for us establishments at Balasor, also in Orissa, and at Húglí, some miles above Calcutta. The vexations and extortions to which the Company's early agents were subjected more than once almost induced them to abandon the trade, and in 1677–78 they threatened to withdraw from Bengal altogether. In 1685, the Bengal factors, driven to extremity by the oppression of the Mughul governors, threw down the gauntlet; and after various successes and hair-breadth escapes, purchased from the grandson of Aurangzeb in 1696, the villages which have since grown up into Calcutta, the metropolis of India. During the next fifty years the English had a long and hazardous struggle alike with the Mughul governors of the province and the Marhattá armies which invaded it. In 1756 this struggle culminated in the great outrage known as the Black Hole of Calcutta, followed by Clive's battle of Plassey and capture of Calcutta, which avenged it. That battle, and the subsequent years of confused fighting, established our military supremacy in Bengal, and procured the treaties of 1765, by which the provinces of Bengal, Behar, and Orissa passed under our administration. To Warren Hastings (1772–85) belongs the glory of consolidating our power, and converting a military occupation into a stable civil government. To another member of the civil service, John Shore, afterwards Lord Teignmouth (1786–93), is due the formation of a regular system of Anglo-Indian legislation. Acting through Lord Cornwallis, then Governor-General, he ascertained and defined the rights of the landholders in the soil. These landholders under the native system had, for the most part, started as collectors of the revenues, and gradually acquired certain prescriptive rights as quasi-proprietors of the estates entrusted to them by the Government. In 1793 Lord Cornwallis declared their rights perpetual, and made over the land of Bengal to the previous quasi-proprietors or *zamíndárs*, on condition of the payment of a fixed land tax. This great piece of legislation is known as the Permanent Settlement of the Land Revenue. But the Cornwallis code, while defining the rights of the proprietors, failed to give adequate recognition to the rights of the under-tenants and the cultivators. His Regulations formally *reserved* the latter class of rights, but did not legally define them, or enable the husbandmen to enforce them in the courts. After half a century of rural disquiet, the rights of the cultivators were at length carefully formulated by Act X. of 1859. This measure, now known as the land law of Bengal, effected for the rights of the under-holders and cultivators what the Cornwallis code in 1793 had effected for those of the superior landholders. The status of each class of person interested in the soil, from the Government as suzerain, through the *zamíndárs* or superior landholders, the intermediate tenure-holders, and the under-tenants, down to the actual cultivator, is now clearly defined. The Act dates from the first year after the transfer of India from the Company to the Crown; for, meanwhile, the mutiny had burst out in 1857. The transactions of that revolt chiefly took place in Northern India, and will be found under the article on the North-Western Provinces; the uprising, although fierce and for a time perilous to our supremacy, was quickly put down. In Bengal it began at BARRACKPUR (*q.v.*), was communicated to Dacca in Eastern Bengal, and for a time raged in Behar, producing the memorable defence of the billiard-room at Arrah by a handful of civilians and Sikhs,—one of the most splendid pieces of gallantry in the history of the British arms. Since 1858, when the country passed to the Crown, the history of Bengal has been one of steady and peaceful progress. The two great lines of railway, the East Indian and the Eastern Bengal, have been completed; and a third, the Northern Bengal Railway, is now in progress. Trade has enormously expanded; new centres of commerce have sprung up in spots which not long ago were silent jungles; new staples of trade, such as tea and jute, have rapidly attained importance; and the coal-fields and iron ores are beginning to open up prospects of a new and splendid era in the internal development of the country.

The best account of Bengal as at present constituted is to be found in the administration reports of Sir George Campbell, K.C.S.I., when lieutenant-governor of Bengal, in 1871–72 and 1872–73. These reports are of an official character, and embody the results of the census of 1872. Among non-official works Colonel Dalton's great volume on *The Ethnology of Bengal* holds a conspicuous place. This splendid quarto condenses the personal observations of a long career spent among the people. Stewart's *History of Bengal*, a work which was admirable when first published, is now fifty years out of date, and stands in much need of re-editing. The journals of the Asiatic societies in London, Paris, and especially Calcutta, are still the great storehouses for original research. The *Calcutta Review* contains many valuable articles, which the index to its first fifty volumes renders easily available. The present writer has endeavoured in his *Annals of Rural Bengal*, and in his two volumes on *Orissa; or, the Vicissitudes of an Indian Province under Native and British Rule*, to present to the general reader the result of his researches with regard to this part of India. (W. W. H.)

BENGAZI, a seaport town on the northern coast of Africa, and capital of the province of Barca, is situated on a narrow strip of land between the Gulf of Sidra and a salt lake, in 30° 7′ N. lat. and 20° 3′ E. long. Though for the most part poorly built, it has one or two buildings of some pretension—an ancient castle, a mosque, a Franciscan monastery, Government buildings, and barracks. The wells in the town being brackish, drinking water has to be brought from the village of Sowani. The harbour is almost rendered useless by accumulations of sand, and ships have to discharge by means of lighters. Legitimate trade has recently been neglected by the inhabitants, who find it more profitable to furnish slaves to the Alexandrian market. The exports, which consist chiefly of sheep, wool, barley, wheat, butter, and salt, amounted in 1874 to £279,000, while the imports, of which the most important item is cloth goods, were valued at £162,600. Consuls are maintained at Bengazi by England and Italy, and France is represented by a vice-consul. The population, estimated in 1862 at 6000 or 7000, has since undergone various fluctuations, and suffered especially from an epidemic in 1872.

BENGEL, JOHN ALBERT, a celebrated Biblical scholar and critic, was born at Winnenden, in Würtemberg, on the 24th June 1687. His father, who was one of the ministers of that town, having died when Bengel was only six years old, his education was taken in hand by a friend of his father named Spindler, who having afterwards become a master in the gymnasium at Stuttgart, carried the boy thither with him, and superintended his education until he entered the University of Tübingen in the year 1703. While at the university, the works to which, among others, he gave special attention as private studies were those of Aristotle and Spinoza. and so thoroughly did he make himself acquainted with the metaphysics of the latter, that he was selected by one of the professors to prepare materials for a treatise *De Spinosismo* which the professor afterwards published. He himself used to express his "great thankfulness for the benefit which he had derived from the study of metaphysics and mathematics, in respect of the clearness of thought which they imparted, which was of the utmost value to him in the analysis and exposition of the language of Scripture." After taking his degree, Bengel devoted himself to the study of theology, to which the grave and religious tone of his mind, deepened and strengthened by his early training and discipline, naturally inclined him. Like other young men of thoughtful character, before and since, he had to struggle with doubts and difficulties of a religious nature, and he alludes, with much feeling, to the "many arrows which pierced his poor heart, and made his youth hard to bear." It is interesting to know that at this early date his attention was directed to the various readings of the Greek New Testament, and that one cause of his mental perplexities was the difficulty of ascertaining the true reading among the great number of those which were presented to his notice. In 1707 Bengel entered the church, and was appointed to the parochial charge of Metzingen-unter-Urach. Here he remained only one year, and during that time devoted himself to the study of the writings of Spener, Arndt, A. H. Franke, and Chemnitz. The profound impression which the works of these men made upon his mind was never effaced, and may be traced in that vein of devotional, not to say pietistic, feeling which runs through all his religious compositions. In 1708 Bengel was recalled to Tübingen to undertake the office of *Repetent* or theological tutor. Here he remained until 1713, when he was appointed the head of a seminary recently established at Denkendorf and intended as a preparatory school of theology. Before entering on his duties there, he made a literary journey through the greater part of Germany, to acquaint himself with the various systems of education which were in use, in order to qualify himself for the better discharge of his official duties. In prosecuting the journey he visited with laudable impartiality the seminaries of the Jesuits as well as those of the Lutheran and Reformed Churches. Among other places he visited Heidelberg and Halle, and had his attention directed at the former city to the canons of Scripture criticism published by Gerhard von Mästricht, and at the latter to Vitringa's *Anacrisis ad Apocalypsin.* The influence exerted by these upon his theological studies will be apparent when we come to notice his works upon the criticism and interpretation of Scripture. For twenty-eight years—from 1713–1741—he discharged his important duties as head of the school of Denkendorf with distinguished ability and success, devoting all his energies to the religious and intellectual improvement of his students. It is impossible to read the extracts from his diary and correspondence, which have been preserved, without being struck with the spirit of fervent piety, combined with sagacity and good sense, which characterized his management of the institution. These twenty-eight years were the period of Bengel's greatest intellectual activity, many of the works on which his reputation rests being included within them. In 1741 he was appointed prelate of the cloister of Herbrechtingen, an office which he held for eight years. In 1749 he was raised to the dignity of consistorial counsellor and prelate of Alpirsbach, with a residence in Stuttgart. Bengel henceforth devoted himself to the discharge of his duties as a member of the consistory. A question of considerable difficulty was at that time occupying the attention of the church courts, viz., the manner in which those who separated themselves from the church were to be dealt with, and the amount of toleration which should be accorded to meetings held in private houses for the purpose of religious edification. The civil power (the duke of Würtemberg was a Roman Catholic) was disposed to have recourse to measures of repression, while the members of the consistory, recognizing the good effects of such meetings, were inclined to concede a considerable degree of liberty. Bengel exerted himself on the side of the latter. The admirer of Spener, the founder of the *collegia pietatis*, could not but show himself favourably disposed to meetings held for religious purposes, and while maintaining the rights and privileges of the church, he was an advocate for all reasonable freedom being accorded to those who felt themselves bound on grounds of conscience to withdraw from her communion. The good effects of this policy may be seen at this day in the attitude taken up by those who in Würtemberg have separated from the church. Bengel's public position necessarily brought him into contact with many individuals of celebrity, by whom he was consulted on all important theological and ecclesiastical questions. In a single year he received no fewer than 1200 letters. In the year 1751 the University of Tübingen, his own *alma mater*, conferred upon him the degree of doctor of divinity. Bengel's life was now drawing to a close. He died, after a short illness, in 1752, aged sixty-five years and four months. He himself is reported to have said, "I shall be forgotten for a while, but I shall again come into remembrance;" and his favourite pupil Oetinger remarked of him, "His like is not left in Würtemberg."

The works on which Bengel's reputation rests as a Biblical scholar and critic are, his edition of the Greek New Testament, and his *Gnomon* or *Exegetical Commentary* on the same.

(A.) His edition of the Greek Testament was published in 4to at Tübingen in 1734, and in 8vo at Stuttgart in the same year, but without the critical apparatus. So early as 1725 he had given an account in his *Prodromus Novi Testamenti Græci recte cauteque adornandi* of the principles on which his intended edition was to be based. In preparation for his work Bengel was able to avail himself of the collations of upwards of twenty MSS., none of them, however,

of great importance, twelve of which had been collated by himself. In constituting the text, he imposed upon himself the singular restriction of not inserting any various reading which had not already been *printed* in some preceding edition of the Greek text. From this rule, however, he deviated in the case of the Apocalypse, where, owing to the corrupt state of the text, he felt himself at liberty to introduce some readings on manuscript authority. In the lower margin of the page he inserted a selection of various readings, the relative importance of which he denoted by the first five letters of the Greek alphabet in the following manner:—*α* was employed to denote the reading which in his judgment was the true one, although he did not venture to place it in the text; *β*, a reading better than that in the text; *γ*, one equal to the textual reading; *δ* and *ε*, readings inferior to those in the text. Stephens's division into verses was retained in the inner margin, but the text was divided into paragraphs. The text was followed by a critical apparatus, the first part of which consisted of an introduction to the criticism of the New Testament, in the thirty-fourth section of which he laid down and explained his celebrated canon, "*Proclivi Scriptioni præstat ardua*" ("The more difficult reading to be preferred to that which is more easy"), the soundness of which, as a general principle, has been recognized by succeeding critics, although it was objected to by his great opponent Wetstein, who, nevertheless, found "himself ultimately obliged to lay down something nearly to the same effect" (Scrivener). The second part of the critical apparatus was devoted to a consideration of the various readings, and here Bengel adopted the plan of stating the evidence both *against* and *in favour* of a particular reading, thus placing before the reader the materials for forming a judgment. It is a proof of Bengel's great critical sagacity that he was the first definitely to propound the theory of families or recensions of MSS. His investigations had led him to see that a certain affinity or resemblance existed amongst many of the authorities for the Greek text—MSS., versions, and ecclesiastical writers; that if a peculiar reading, *e.g.*, were found in one of these, it was generally found also in the other members of the same class; and this general relationship seemed to point ultimately to a common origin for all the authorities which presented such peculiarities. Although disposed at first to divide the various documents into three classes, he finally adopted a classification into two—the African, or older family of documents, and the Byzantine, or more recent class, to which he attached only a subordinate value. The theory was afterwards adopted by Semler and Griesbach, and worked up into an elaborate system by the latter critic. Bengel's labours on the text of the Greek Testament were received with great disfavour in many quarters. Like Walton and Mill before him, he had to encounter the opposition of ignorant and fanatical individuals who believed that the certainty of the Word of God was endangered by the importance attached to the various readings, as if the received text were possessed of infallible authority. One of his opponents, Provost Kohlreif, publicly challenged him to put the enemies of criticism to silence by admitting that even the various readings were given by inspiration, in order to meet the necessities of various classes of readers! Wetstein, on the other hand, accused him of excessive caution in not making freer use of his critical materials. In answer to these strictures, Bengel published a *Defence of the Greek Text of his New Testament*, which he prefixed to his *Harmony of the Four Gospels*, published in 1736, and which contained a sufficient answer to the misrepresentations, especially of Wetstein, which had been brought against him from so many different quarters. The text of Bengel long enjoyed a high reputation amongst scholars, and was frequently reprinted.

(B.) The other great work of Bengel, and that on which his reputation as an exegete is mainly based, is his *Gnomon, or Exegetical Annotations on the New Testament*, published in 1742. It was the fruit of twenty years' labour, and exhibits with a pregnant brevity of expression, which, it has been said, "condenses more matter into a line than can be extracted from pages of other writers," the results of his study of the sacred volume. He modestly entitled his work a *Gnomon* or index, his object being rather to guide the reader to ascertain the meaning for himself, than to save him from the trouble of personal investigation. The principles of interpretation on which he proceeded were, to import nothing *into* Scripture, but to draw *out of* it everything that it really contained, in conformity with grammatico-historical rules; not to be hampered by dogmatical considerations; and not to be influenced by the symbolical books. Bengel's hope that the *Gnomon* would help to rekindle a fresh interest in the study of the New Testament was fully realized. It has passed through many editions (latest 1850), has been translated into German and into English, and is still one of the books most highly prized by the expositor of the New Testament. It is a striking testimony to its value that John Wesley largely availed himself of it in writing his *Expository Notes upon the New Testament*, 1755, saying that he "believed he would much better serve the interests of religion by translating from the *Gnomon* than by writing many volumes of his own notes." Later commentators have not failed to follow Wesley's example.

Besides the two works already described, Bengel was the editor or author of many others, classical, patristic, ecclesiastical, and expository, which our limits do not allow us to discuss. We can only name two, viz., *Ordo Temporum*, a treatise on the chronology of Scripture, in which he enters upon speculations regarding the end of the world, and an *Exposition of the Apocalypse*, which enjoyed for a time extraordinary popularity in Germany, and was translated into several foreign languages.

For full details regarding Bengel the reader is referred to the *Memoir of his Life and Writings*, by J. C. F. Burk, translated into English by Rev. R. F. Walker, London, 1837. (F. C.)

BENGUELA, a country on the western coast of Africa, situated to the south of Angola, between 10° and 17° S. lat., and extending from the River Coanza to the Cunene, which is otherwise known as Nourse, Rio das Trombas, Rio dos Elephantes. The country rises from the coast inwards till it attains a decidedly mountainous character. There is great abundance both of vegetable and animal life; and the higher regions contain mines of copper, silver, iron, and salt. The inhabitants belong to the Congo race and speak the Bunda language. In 1617 the Portuguese under Manoel Cerveira Pereira founded the town of S. Felipe de Benguela near the mouth of the Cavaco, on the Bahia das Vacas (Santo Antonio, or Cone's Bay), in 12° 34′ S. lat. and 13° 20′ E. long. It was long the centre of an important trade, especially in slaves, but has now greatly declined. There is but little traffic, and no manufactures. Besides the churches of S. Felipe and S. Antonio, the hospital, and the fortress, there are only a few stone-built houses. The negro town of Catombela, about 8 miles distant, is in a more flourishing condition. A short way beyond Benguela is Bahia Tarta, where salt is manufactured and sulphur excavated. The town of Old Benguela is situated about 130 miles to the N.; and about 80 miles in that direction lies the Presidio of Novo Redondo, where fortifications were erected in 1769. Among the more important inland towns are Bihé, Bailundo, and Caconda, in the last of which the Portuguese have long had a fortress. The southern portion of Benguela forms the separate government of Mossamedes, of which the capital of the same name is situated on the Bay of Mossamedes at the mouth of the River Béro (Rio das Mortes). The bay was formerly called Angra do Negro, and received its present designation in honour of Baron Mossamedes about 1785. The town, which is known to the natives as Mossongo-Bittolo, was not founded till 1840. The population of the whole territory of Benguela is estimated at about 140,000.

BENICARLO, a city of Spain, in the province of Castellon, on the coast of the Mediterranean. It is surrounded by ancient walls, and has a ruined castle. The manufacture of brandy is carried on, and the town is celebrated for its red wine, which is annually exported to Bordeaux for mixing with clarets and other French wines. The value of wine exported in 1869 was £9500. Population, 7000.

BENIN, a country, city, and river of Western Africa, to the west of the main channel of the Niger. The name was formerly applied to the whole stretch of coast from the Volta, in 0° 40′ E. long., to the Rio del Rey or Riumbi, in 8° 40′ E. long., including what is now known as the Slave Coast, the whole delta of the Niger, and a small portion of the country to the eastward; and some trace of this earlier application remains in the name of *Bight of Benin*, still given to that part of the sea which washes the Slave Coast. The kingdom of Benin seems at one time to have been one of the most powerful of Western Africa, and was known to Europeans in the 17th century as the Great Benin. Budagry and Lagos, now British possessions, are both Beninese colonies. Benin has now been long in a state of decline, and the territory is broken up into independent states of no individual importance. Such coherence, indeed, as still exists is rather ethnographical

than territorial; but it may be regarded as bounded on the E. by the Niger, N. by the Yoruba country, and W. by Egba. The soil is highly fertile and produces palms, rice, beans, maize, kokos, plantains, cotton, sugar, and Guinea pepper, in great abundance. The papaw and African plum grow wild, and excellent tobacco can be raised. Many parts of the country are covered with almost impenetrable forests and swamps, but towards the north there is fine pasture land, in which the natives rear both cattle and horses of considerable value. Of trees the cotton wood, the tamarind, and the mangrove are the most frequent. The population is pretty dense, and it is said that in the most flourishing state of the kingdom the king could collect 100,000 men. His rule is absolute, and he is revered by his subjects as a species of divinity. It is a crime to believe that the king either eats or sleeps; and all offences against him are punished with the utmost severity. The religion and mythology agree with the great system of Yoruba and Oro; the chief god is worshipped with human sacrifices to an appalling extent. The people, at the same time, do not indulge in wanton cruelty; they usually stupefy the victims before putting them to death. The houses, at least of the better classes, are built on a plan similar to that of the Romans, with a regular *atrium* and *impluvium*. The Beninese weave their cotton into a fine kind of muslin, which is worn in huge bulging petticoats by people of wealth, while the lower orders are content with a simple *Beluko* or kilt. The capital of the kingdom, or city of Benin, is situated about 73½ miles inland from the mouth of the Rio Formoso or Benin River, about 5° 35′ E. long. and 6° 25′ N. lat. It covers a large extent of ground, but is so broken up into separate portions by intervening spaces of jungle, that no proper estimate can be formed of its population. The Obwe, or King's quarter, alone is supposed to have upwards of 15,000 inhabitants; but at the time of Burton's visit in 1862 many of the houses were empty and falling to ruin. The next city in importance is Wari (Owari, Awerri, or Owheyre, called Jaku by the natives), which is situated about 130 miles S.S.E. of the capital, and some 7 or 10 miles, from the sea, on an island surrounded by a branch of the Niger distinguished by the same name. It was formerly described as consisting of two parts about half a mile distant from each other, but now consists of one long and straggling line along the shore. The population previously stated at 5000 is reduced by Burton to 2000. The town, however, has its own king, who has long asserted his independence of the monarch of Benin. The houses are neatly built of clay, coloured with red ochre, and frequently ornamented with rudely carved pillars. The port of Gwato (or as it is variously called, Gato, Agatho, or Agatton) lies about 30 miles N.N.E. of the mouth of the Benin River, is a place of some importance for the palm-oil trade, and has a special interest as the place where Belzoni, the traveller, died and was buried. Numerous factories are scattered along the creeks of the delta for the purposes of trade, but all the larger European settlements have disappeared. Since the abolition of the slave trade the chief export of the country is palm-oil, in return for which salt, silk stuffs, guns and gunpowder, coral (which is the official decoration of the higher dignities), beads, iron, brass, and brandy are imported. The common internal currency is the cowrie-shell.

The River Benin, called by the natives Uwo Ko Jakri, or Outlet of Jakri, is about two miles broad at its mouth; but it is crossed by a very extensive bar of mud and sand, on which there is only 12 feet of water at spring tides. Ships of 60 tons can ascend as far as Gwato.

Benin was discovered by the Portuguese about the year 1485, and they carried on for some time a brisk trade in slaves, who were carried to Elmina, and sold to the natives of the Gold Coast. John III. of Portugal, however, prohibited this traffic; and, as the situation was found very unhealthy, the settlement was ordered to be withdrawn. Many traces of the Portuguese occupation are still to be found, and one of the most striking proofs of their influence is the fact that a corrupt Lusitanian dialect is still spoken by the older natives. The Dutch afterwards established factories, and maintained them for a considerable time, chiefly with a view to the slave trade. In 1788 Captain Landolphe founded a factory called Barodo, near the native village of Obobi, for the French Compagnie d'Oywheré; and it lasted till 1792, when it was destroyed by the English. See Bosman's *Description of the Coast of Guinea in* 1705 (in vol. xvi. of Pinkerton's *Voyages*); William Smith's *New Voyage to Guinea*, 1744; Adams's *Remarks on the West Coast of Africa*, 1823; Clapperton's *Second Expedition*, 1829; Lander's *Travels*, 1832; Burton's *My Wanderings in West Africa*, 1863.

BENJAMIN (בִּנְיָמִין, Sept. Βενιαμίν), the youngest son of the Patriarch Jacob, by Rachel. His mother, dying in childbed, gave him the name Benoni, "Son of my pain," which was changed by his father to Benjamin, meaning probably "Son of the right hand," that is, "Son of prosperity" (Gen. xxxv. 16–18). Of his personal history little is recorded. He was the favourite of his father and brothers, and seems to have been of an amiable though somewhat weak character. In this respect he strikingly contrasts with the tribe, whose history was foretold in the dying prophecy of Jacob, "Benjamin shall ravin as a wolf" (Gen. xlix. 27). The tribe of Benjamin, though the least numerous of Israel, became nevertheless a considerable race. In the desert it counted 35,400 warriors (Num. i. 37), and at the entrance of Israel into Canaan even as many as 45,600 (Num. xxvi. 41). The portion allotted to this tribe was encompassed by the districts of Ephraim, Dan, and Judah. In the time of the judges the tribe of Benjamin became involved in a civil war with the other eleven tribes, which terminated in its almost utter extinction, 600 men alone escaping (Judges xix., xx.) The tribe speedily revived, however; in the time of David it numbered 59,434 able warriors, and in that of Asa, 280,000. This tribe had the honour of giving the first king to the Jews, Saul being a Benjamite. After the death of Saul, the Benjamites declared themselves for his son Ishbosheth, until, after the assassination of that prince, David became king of all Israel. David having expelled the Jebusites from Zion, and made it his own residence, the close alliance that previously existed between the tribes of Benjamin and Judah was cemented by the circumstance that, while Jerusalem belonged to the district of Benjamin, that of Judah was immediately contiguous to it. At the division of the kingdom after the death of Solomon, Benjamin espoused the cause of Judah, and they formed a kingdom by themselves. Indeed, the two tribes stood always in such a close connection as often to be included under the single name Judah.

BENJAMIN, of Tudela, in Navarre, a celebrated Jewish rabbi of the 12th century, whose *Itinerary* is a literary curiosity. He visited Constantinople, Egypt, Assyria, and Persia, penetrating to the frontiers of China. He was credulous, but his work contains some curious notices of the countries he visited. It was translated from the Hebrew into Latin by Arias Montanus in 1575, and appeared in a French version by Baratier in 1734, and again in 1830. The latest English translation is that by Asher, 1840.

BENNET, HENRY, Earl of Arlington, a distinguished statesman in the reign of Charles II., was born of an ancient family in Middlesex, in the year 1618. In the beginning of the civil war he was appointed under-secretary to Lord Digby, secretary of state. He afterwards entered himself as a volunteer for the royal cause, and did the king good service, especially at Andover in Hampshire, where he was severely wounded. He was made secretary to the Duke of York, received the honour of knighthood from Charles II. at Bruges in 1658, and was sent as envoy

to the court of Spain. Upon the return of the king to England he was called home, made keeper of the privy purse, and principal secretary of state. In 1670 he was of the council distinguished by the title of the Cabal, and one of those who advised the shutting up of the exchequer. In 1672 he was made Earl of Arlington and Viscount Thetford, and soon after knight of the garter.

"Henry Bennet, Lord Arlington, then secretary of state, had, since he came to manhood, resided principally on the Continent, and had learned that cosmopolitan indifference to constitutions and religions which is often observable in persons whose life had been passed in vagrant diplomacy. If there was any form of government he liked, it was that of France. If there was any church for which he felt a preference, it was that of Rome. He had some talent for conversation, and some talent also for transacting the ordinary business of office. He had learned, during a life passed in travelling and negotiating, the art of accommodating his language and deportment to the society in which he found himself. His vivacity in the closet amused the king; his gravity in debates and conferences imposed on the public; and he had succeeded in attaching to himself, partly by services and partly by hopes, a considerable number of personal retainers."—(Macaulay's *Hist.*, vol. i. pp. 220–21.)

He died in 1685. His *Letters to Sir William Temple* were published after his death.

BENNETT, James Gordon, American journalist, originator and editor of the *New York Herald*, was by birth a Scotchman. He was born at Newmills in Banffshire, about 1800. Destined for the priesthood in the Roman Catholic Church, he was educated in a seminary at Aberdeen. But it became evident that he was naturally unfit for the priestly calling; and his aversion ripened into a determination to escape from it. The reading of Franklin's *Autobiography* led him to resolve on emigration to America, and in the spring of 1819 he sailed for the New World. Landing at Halifax, he earned a poor living there for a short time by giving lessons in French, Spanish, and bookkeeping; he passed next to Boston, where starvation almost threatened him till he got employment in a printing-office; and in 1822 he went to New York. An engagement as translator of Spanish for a newspaper took him for a few months to Charleston, South Carolina. On his return to New York he projected a school, gave lectures on political economy, and did subordinate work for the journals. In 1825 he made his first attempt to establish a journal of his own; and the next ten years were occupied in a variety of similar attempts, which proved futile. During that period, however, he became Washington correspondent of the *Inquirer*; and his letters, written in imitation of the letters of Horace Walpole, attracted attention. Notwithstanding all his hard work and his resolutely abstemious life, he was still a poor man. It was not till 1835 that he struck the vein which was to reward and enrich him. On May 6 of that year appeared the first number of a small one-cent paper, bearing the title of *New York Herald*, and issuing from a cellar, in which the proprietor and editor played also the part of salesman. "He started with a disclaimer of all principle, as it is called, all party, all politics;" and to this he certainly adhered. By his immense industry and practical sagacity, his unscrupulousness, variety of news, spicy correspondence, supply of personal gossip and scandal, the paper became a great commercial success. Bennett continued to edit the *Herald* till his death. The successful mission of Stanley to Central Africa in search of Dr. Livingstone, of whom nothing had long been heard, was undertaken by his desire and at his expense; and he thus showed in the last year of his life the inextinguishable spirit of enterprise which had animated him throughout his whole career. He died at New York, June 2, 1872.

BENNETT, John Hughes, for twenty-six years professor of the institutes of medicine at Edinburgh University, was born in London on the 31st August 1812. He was educated at Exeter, and being destined for the medical profession was articled to a surgeon in Maidstone. In 1833 he began his studies at Edinburgh, and in 1837 graduated with the highest honours. During the next four years he studied in Paris and Germany, and on his return to Edinburgh in 1841 published a work on cod-liver oil, the recommendation of which as a remedy in all consumptive diseases made his name widely known. In 1848 he obtained the chair of institutes of medicine, having already gained high reputation as an extra-academical lecturer and teacher. In 1871 his health gave way; he retired to the south of France, and in 1874 resigned his professorship. In August 1875 he was able to be present at the meeting of the British Medical Association in Edinburgh, on which occasion he received the degree of LL.D. The fatigue he then underwent brought on a relapse, and he was compelled to have the operation of lithotomy performed. He sank rapidly and died on the 25th September. Professor Bennett was an able teacher, and his original investigations entitle him to a high place in the history of medicine. His publications are very numerous, including many articles in medical journals and several exhaustive treatises. Of these the best known are *Clinical Lectures*, 1858 (5th ed., 1868); *Treatise on Physiology*, 1858, contributed to the 8th edition of the *Encyclopædia Britannica*; *Text-book of Physiology*, 1870.

BENNETT, Sir William Sterndale, was considered, for more than the last 20 years of his life, the head of the musical profession in England by the unanimous verdict of both English and foreign musicians. At his death he received the highest honour England can confer upon her sons—a grave in Westminster Abbey. He was born in 1816 at Sheffield, where his father was organist. Having lost his father at an early age, he was brought up at Cambridge by his grandfather, from whom he received his first musical education. In 1826 he entered the Royal Academy of Music, and remained a pupil of that institution for the next ten years, studying pianoforte and composition under Cipriani Potter, Dr. Crotch, W. H. Holmes, and C. Lucas. It was during this time that he wrote several of his most appreciated works, not uninfluenced it seems by the contemporary movement of musical art in Germany, which country he frequently visited during the years 1836–42. At one of the Rhenish musical festivals in Dusseldorf he made the personal acquaintance of Mendelssohn, and soon afterwards renewed it at Leipsic, where the talented young Englishman was welcomed by the leading musicians of the rising generation. He played at one of the celebrated Gewandhaus concerts his third pianoforte concerto, which was received by the public in a manner flattering both to the pianist and the composer. We still possess an enthusiastic account of the event from the pen of Robert Schumann, whose genial expansive nature was always open to new impressions. He never tired of Bennett's praise, whom he pronounced to be "the most musical of all Englishmen," and whom, in a private letter, he goes so far as to call "an angel of a musician." But even Schumann could not wholly conceal from himself the influence which Mendelssohn's compositions exercised on Bennett's mode of utterance, an influence which precluded the possibility of an original development to a degree almost unequalled in the history of music, excepting perhaps the case of the Danish composer Niels W. Gade, who like Bennett was attracted to Leipsic by the fame of Mendelssohn, and who like him offered his own artistic individuality at the shrine of the German composer's genius. According to a tradition, the late Professor Hauptmann, after listening to a composition by Gade, is said to have pronounced the sarcastic sentence, "This sounds so much like Mendelssohn, that one might

almost suppose it to be written by Sterndale Bennett." It would lead us too far on the present occasion to point out how, by this subserviency of the leading English musician to a foreign composer, the national development of English art was impeded in a deplorable manner. His great success on the Continent established Bennett's position in England. He settled in London, devoting himself chiefly to practical teaching. For a short time he acted as conductor of the Philharmonic Society, in which capacity, however, he earned little success. He was made musical professor at Cambridge in 1856, and in 1868 principal of the Royal Academy of Music. In 1871 he received the honour of knighthood. He died in 1875. Owing most likely to his professional duties his latter years were not fertile, and what he then wrote was not superior, scarcely equal, to the productions of his youth. The principal charm of Bennett's compositions (not to mention his absolute mastery of the musical form) consists in the tenderness of their conception, rising occasionally to sweetest lyrical intensity, but also bordering now and then on that excessive sentimentalism from which his master Mendelssohn kept not always aloof. It must, however, be acknowledged that Bennett's was a thoroughly refined nature, incapable of grand dramatic pathos, but also free from all inartistic pandering to the taste of the vulgar. Barring the opera, Bennett tried his hand at almost all the different forms of vocal and instrumental writing. As his best works in various branches of art, we mention, for pianoforte solo, and with accompaniment of the orchestra, his three sketches, *The Lake, the Millstream, and the Fountain*, and his 3d pianoforte concerto; for the orchestra, his Symphony in G minor, and his overture *The Naiads;* and for voices, his cantata *The May Queen*, written for the Leeds festival in 1858. He also wrote a sacred cantata, *The Woman of Samaria*, first performed at the Birmingham Musical Festival in 1867. Shortly before his death he produced a sonata called the *Maid of Orleans*, an elaborate piece of programme-music, descriptive of the deeds and sufferings and the final triumph of the French heroine according to Schiller's tragedy.

BENSERADE, Isaac de, a French poet, was born in 1612 at Lions-la-Forêt in Normandy. He made himself known at court by his verses and his wit, and had the good fortune to please the cardinals Richelieu and Mazarin. He wrote—1. A Paraphrase upon Job; 2. Verses for Ballets or Interludes; 3. Rondeaux upon Ovid; 4. Several Tragedies. A sonnet of his, which he sent to a young lady with his paraphrase on Job, having been placed in competition with the *Urania* of Voiture, a dispute on their relative merits long divided the whole court and the wits into two parties, who were respectively styled the *Jobelins* and the *Uranists*. Some years before his death in 1691 Benserade retired to Chantilly, and devoted himself to a translation of the Psalms, which he nearly completed.

BENSON, George, a learned dissenting minister, was born at Great Salkeld, in Cumberland, in 1699. His mental capacity was so precocious, that at 11 years of age he was able to read the Greek Testament. He afterwards studied at an academy at Whitehaven, whence he removed to the University of Glasgow. In 1721 he was chosen pastor of a congregation of dissenters at Abingdon, in Berkshire, where he continued till 1729, when he became the choice of a congregation in Southwark; and in 1740 he was appointed by the congregation of Crutched Friars colleague to the learned Dr Lardner. His *Defence of the Reasonableness of Prayer* appeared in 1731, and he afterwards published Paraphrases and Notes on the Epistles to the Thessalonians, Timothy, Titus, and Philemon, adding dissertations on several important subjects, particularly on inspiration. In 1735 he published his *History of the First Planting of Christianity*, in 2 vols. 4to, a work of great learning and ability. He also wrote the *Reasonableness of the Christian Religion*, the *History of the Life of Jesus Christ*, a Paraphrase and Notes on the Seven Catholic Epistles, and several other works, which gained him great reputation as a scholar and theologian. He died in 1763.

BENTHAM, Jeremy, was born on the 15th February 1748, in Red Lion Street, Houndsditch, London, in which neighbourhood his grandfather and father successively carried on business as attorneys. His father, who was a wealthy man, and possessed at any rate a smattering of Greek, Latin, and French, was thought to have demeaned himself by marrying the daughter of an Andover tradesman, who afterwards retired to a country house near Reading, where young Jeremy spent many happy days. The boy's talents justified the ambitious hopes which his parents entertained of his future. When three years old he read eagerly such works as Rapin's *History*, and began the study of Latin. A year or two later he learnt the violin and French conversation. At Westminster school he obtained a reputation for Greek and Latin verse writing; and he was only thirteen when he was matriculated at Queen's College, Oxford, where his most important acquisition seems to have been a thorough acquaintance with Sanderson's logic. He became a B.A. in 1763, and in the same year entered at Lincoln's Inn, and took his seat as a student in the Queen's Bench, where he listened with rapture to the judgments of Lord Mansfield. He managed also to hear Blackstone's lectures at Oxford, but says that he immediately detected the fallacies which underlay the rounded periods of the future judge.

Bentham's family connections would naturally have given him a fair start at the bar, but this was not the career for which he was preparing himself. He spent his time in making chemical experiments and in speculating upon legal abuses, rather than in reading Coke upon Littleton and the Reports. On being called to the bar he "found a cause or two at nurse for him, which he did his best to put to death," to the bitter disappointment of his father, who had confidently looked forward to seeing him upon the woolsack. The first fruits of Bentham's studies, the *Fragment on Government*, appeared in 1776. This masterly attack upon Blackstone's praises of the English constitution was variously attributed to Lord Mansfield, Lord Camden, and Lord Ashburton. One important result of its publication was that, in 1781, Lord Shelburne called upon its author in his chambers at Lincoln's Inn. Henceforth Bentham was a frequent guest at Bowood, where he saw the best society, and where he met Miss Caroline Fox, to whom he afterwards made a proposal of marriage. In 1785 Bentham started, by way of Italy and Constantinople, on a visit to his brother, Sir Samuel Bentham, who became a general in the Russian service; and it was in Russia that he wrote his *Defence of Usury*. Disappointed in the hope which he had entertained, through a misapprehension of something said by Lord Lansdowne, of taking a personal part in the legislation of his country, he settled down to the yet higher task of discovering and teaching the principles upon which all sound legislation must proceed. His fame spread widely and rapidly. He was made a French citizen in 1792; and his advice was respectfully received in most of the states of Europe and America, with many of the leading men of which he maintained an active correspondence. His ambition was to be allowed to prepare a code of law for his own or some foreign country. During nearly a quarter of a century he was engaged in negotiations with Government for the erection of a "Panopticon," which would render transportation unnecessary. The scheme was eventually abandoned, and Bentham received £23,000 by

way of compensation. In 1823 he established the *Westminster Review*. Some idea of the extent of Bentham's literary labours may be derived from the fact that his *Works*, as edited with biographical notices by Dr Bowring in 1843, fill eleven volumes octavo, of closely printed double columns. Bentham died on the 6th of June 1832, in his 85th year, at the house in Queen's Square Place, which he had occupied for fifty years. In accordance with his directions, his body, after being dissected in the presence of his friends, was embalmed, and is still preserved, seated in his wonted dress, in University College, London.

Bentham's life was a happy one of its kind. His constitution, weakly in childhood, strengthened with advancing years so as to allow him to get through an incredible amount of sedentary labour, while he retained to the last the fresh and cheerful temperament of a boy. An ample inherited fortune permitted him to pursue his studies undistracted by the necessity for making a livelihood, and to maximize the results of his time and labour by the employment of amanuenses and secretaries. He was able to gather around him a group of congenial friends and pupils, such as the Mills, the Austins, and Bowring, with whom he could discuss the problems upon which he was engaged, and by whom several of his books were practically rewritten, from the mass of rough though orderly memoranda which the master had himself prepared. Thus, for instance, was the *Rationale of Judicial Evidence* written out by J. S. Mill, and the *Book of Fallacies* by Bingham. The services which Dumont rendered in recasting, as well as translating, the works of Bentham were still more important.

The popular notion that Bentham was a morose visionary is far removed from fact. It is true that he looked upon general society as a waste of time, and that he disliked poetry as "misrepresentation"; but he intensely enjoyed conversation, gave good dinners, and delighted in music, in country sights, and in making others happy. These features of Bentham's character are illustrated in the graphic account given by the American minister, Mr Rush, of an evening spent at his house in the summer of the year 1818. "If Mr Bentham's character is peculiar," he says, "so is his place of residence. It was a kind of blind-alley, the end of which widened into a small, neat courtyard. There by itself stands Mr Bentham's house. Shrubbery graced its area, and flowers its window-sills. It was like an oasis in the desert. Its name is the Hermitage. Mr Bentham received me with the simplicity of a philosopher. I should have taken him for 70 or upwards. Everything inside the house was orderly. The furniture seemed to have been unmoved since the days of his fathers, for I learned that it was a patrimony. A parlour, library, and dining-room made up the suite of apartments. In each was a piano, the eccentric master of the whole being fond of music as the recreation of his literary hours. It is a unique, romantic-like homestead. Walking with him into the garden, I found it dark with the shade of ancient trees. They formed a barrier against all intrusion. The company was small, but choice. Mr. Brougham; Sir Samuel Romilly; Mr Mill, author of the well-known work on India; M. Dumont, the learned Genevan, once the associate of Mirabeau, were all who sat down to table. Mr. Bentham did not talk much. He had a benevolence of manner suited to the philanthropy of his mind. He seemed to be thinking only of the convenience and pleasure of his guests, not as a rule of artificial breeding as from Chesterfield or Madame Genlis, but from innate feeling. Bold as are his opinions in his works, here he was wholly unobtrusive of theories that might not have commended the assent of all present. When he did converse it was in simple language, a contrast to his later writings, where an involved style and the use of new or universal words are drawbacks upon the speculations of a genius original and profound, but with the faults of solitude. Yet some of his earlier productions are distinguished by classical terseness."—(*Residence at the Court of London*, p. 286.) Bentham's love of flowers and music, of green foliage and shaded walks, comes clearly out in this pleasant picture of his home life and social surroundings.

Whether or no he can be said to have founded a school, his doctrines have become so far part of the common thought of the time, that there is hardly an educated man who does not accept as too clear for argument truths which were invisible till Bentham pointed them out. His sensitively honourable nature, which in early life had caused him to shrink from asserting his belief in Thirty-nine articles of faith which he had not examined, was shocked by the enormous abuses which confronted him on commencing the study of the law. He rebelled at hearing the system under which they flourished described as the perfection of human reason. But he was no merely destructive critic. He was determined to find a solid foundation for both morality and law, and to raise upon it an edifice, no stone of which should be laid except in accordance with the deductions of the severest logic. This foundation is "the greatest happiness of the greatest number," a formula adopted from Beccaria. The pursuit of such happiness is taught by the "utilitarian" philosophy, a phrase used by Bentham himself in 1802, and therefore not invented by Mr J. S. Mill, as he supposed, in 1823. In order to ascertain what modes of action are most conducive to the end in view, and what motives are best fitted to produce them, Bentham was led to construct marvellously exhaustive, though somewhat mechanical, tables of motives. With all their elaboration, these tables are, however, defective, as they omit some of the highest and most influential springs of action. But most of Bentham's conclusions may be accepted without any formal profession of the utilitarian theory of morals. They are, indeed, merely the application of a rigorous common sense to the facts of society. That the proximate ends at which Bentham aimed are desirable hardly any one would deny, though the feasibility of the means by which he proposes to attain them may often be questioned; and much of the new nomenclature in which he thought fit to clothe his doctrines may be rejected as unnecessary. To be judged fairly, Bentham must be judged as a teacher of the principles of legislation. With the principles of private morals he really deals only so far as is necessary to enable the reader to appreciate the impulses which have to be controlled by law.

As a teacher of legislation he inquires of all institutions whether their utility justifies their existence. If not, he is prepared to suggest a new form of institution by which the needful service may be rendered. While thus engaged no topic is too large for his mental grasp, none too small for his notice; and, what is still rarer, every topic is seen in its due relation to the rest. English institutions had never before been thus comprehensively and dispassionately surveyed. Such improvements as had been necessitated were mere makeshifts, often made by stealth. The rude symmetry of the feudal system had been long ago destroyed by partial and unskilful adaptations to modern commercial life, effected at various dates and in accordance with various theories. The time had come for deliberate reconstruction, for inquiring whether the existence of many admitted evils was, as it was said to be, unavoidable; for proving that the needs of society may be classified and provided for by contrivances which shall not clash with one another because all shall be parts of a consistent whole. This task Bentham undertook, and he brought to it a mind absolutely free from professional or class feeling, or any other species of

prejudice. He mapped out the whole subject, dividing and subdividing it in accordance with the principle of "dichotomy." Having reached his ultimate subdivisions he subjects each to the most thorough and ingenious discussion. His earlier writings exhibit a lively and easy style, which gives place in his later treatises to sentences which are awkward from their effort after unattainable accuracy, and from the newly-invented technical nomenclature in which they are expressed. Many of Bentham's phrases, such as "international," "utilitarian," "codification," are valuable additions to our language; but the majority of them, especially those of Greek derivation, have taken no root in it. His neology is one among many instances of his contempt for the past and his wish to be clear of all association with it. His was, indeed, a typically logical, as opposed to an historical, mind. For the history of institutions, which in the hands of Sir Henry Maine is becoming a new and interesting branch of science, Bentham cared nothing. Had he possessed such a knowledge of Roman law as is now not uncommon in England, he must doubtless have taken a different view of many subjects. The logical and historical methods can, however, seldom be combined without confusion; and it is perhaps fortunate that Bentham devoted his long life to showing how much may be done by pursuing the former method exclusively. His writings have been and remain a storehouse of instruction for statesmen, an armoury for legal reformers. "Pillé par tout le monde," as Talleyrand said of him, "il est toujours riche." To trace the results of his teaching in England alone would be to write a history of the legislation of half a century. Upon the whole administrative machinery of government, upon criminal law, and upon procedure, both criminal and civil, his influence has been most salutary; and the great legal revolution which has just accomplished the fusion of law and equity is not obscurely traceable to the same source. Those of Bentham's suggestions which have hitherto been carried out have affected the matter, or contents, of the law. There seems at length some reason to hope that his suggestions for the improvement of its form and expression are about to receive the attention which they deserve. The services rendered by Bentham to the world would not, however, be exhausted even by the practical adoption of every one of his recommendations. There are no limits to the good results of his introduction of a true method of reasoning into the moral and political sciences.

The best edition of Bentham's works is that edited by Dr Bowring, in 11 vols. 8vo, the publication of which was completed in 1843. It contains a selection from his correspondence, and some biographical statements. (T. E. H.)

BENTINCK, Lord William George Frederick Cavendish, better known as Lord George Bentinck, the second son of the fourth duke of Portland, by Henrietta, sister to the Viscountess Canning, was born February 27, 1802. He was educated at home until he obtained his commission as cornet in the 10th Hussars, at the age of seventeen. On retiring from the army, he acted for some time as private secretary to his uncle Mr Canning, then prime minister; in which capacity he gave proofs of high ability for the conduct of public business. In 1828 he succeeded his uncle Lord William Bentinck as member for Lynn-Regis, and continued to represent that constituency during the remaining twenty years of his life. Till within three years of his death Lord George Bentinck was little known out of the sporting world. His early attempts at public speaking afforded no indication of the abilities which the subsequent course of political events served to develop so conspicuously. His failures in the House of Commons seem to have discouraged him from the attempt to acquire reputation as a politician. The natural energy of his character, however, found scope in another arena. As one of the leaders on "the turf," he was there distinguished by that integrity, judgment, and indomitable determination, which, when brought to bear upon matters of weightier importance, placed him, with a rapidity almost unexampled, in the foremost rank of British senators. On his first entrance into parliament he belonged to what may be called the moderate Whig party, and voted in favour of Catholic emancipation, as also for the Reform Bill, though he opposed some of its principal details. Soon after, however, he joined the ranks of the Opposition, with whom he sided up to the important era of 1846. When, in that year, Sir Robert Peel openly declared in favour of free trade, the advocates of the corn-laws, then without a leader, after several ineffectual attempts at organization, discovered that Lord George Bentinck was the only man around whom the several sections of the Opposition could be brought to rally. His sudden elevation to so prominent a position took the public mind by surprise; but he soon gave convincing evidence of powers so formidable, that the position of the Protectionist party at once assumed an imposing aspect. Towards Sir Robert Peel, in particular, his hostility was marked and uncompromising. Believing, as he himself expressed it, that that statesman and his political colleagues had "hounded to the death his illustrious relative" Mr Canning, he combined with his opposition as a political leader a degree of personal animosity that gave additional force to the poignancy of his invectives. On entering on his new position, he at once abandoned his favourite pursuits, disposed of his magnificent stud, forsook all connection with the turf, and devoted his whole time and energies to the laborious and trying duties of a parliamentary leader. Apart from the question of the corn-laws, his politics were strictly independent. In opposition to the rest of his party, he supported the bill for removing the Jewish disabilities, and was favourable to the scheme for the payment of the Roman Catholic clergy in Ireland by the landowners. As he had held no high office under Government, his qualifications as a statesman never found scope beyond the negative achievements of a leader of Opposition; but it may be safely affirmed that nothing but his untimely death could have debarred him from acquiring a distinguished position among the statesmen of Britain. This event, caused by the rupture of a vessel in the heart, took place suddenly on the 21st September 1848, while his lordship was proceeding on foot to visit a friend in the country.—(See *Lord George Bentinck; a Political Biography*, by B. Disraeli, 1851.)

BENTIVOGLIO, Giovanni, was born at Bologna about 1438, seven years before the murder of his father Annibale, then the chief magistrate of the republic. In 1462 Giovanni contrived to make himself master of the state, which he continued to rule with a stern sway for nearly half a century; but his encouragement of the fine arts, and his decoration of the city by sumptuous edifices, gilded his usurpation. He was finally expelled by Pope Julian II., in 1506, and died in the state of Milan at the age of seventy.

BENTIVOGLIO, Guido, Cardinal, an eminent statesman and historian, was born at Ferrara in 1579. After studying at Padua, he went to reside at Rome, and was received with great favour by Pope Clement VIII., who made him a prelate. He was sent as nuncio into Flanders, and afterwards to France; and when he returned to Rome he was entrusted by Louis XIII. with the management of the French affairs at that court. In 1621 he was made a cardinal, and in 1641 received the bishopric of Terracina. He was the intimate friend of Pope Urban VIII., and on the death of Urban public opinion marked out Bentivoglio

for his successor. He died suddenly, however, before the election took place. His principal works are, *Della Guerra di Fiandria*, 1632–39; *Relazioni di G. Bentivoglio in tempo delle sue Nunziature di Fiandria e di Francia*, 1631; *Memorie*, 1648; *Lettere*, 1631.

BENTLEY, Richard (born, 1662; died, 1742), was born at Oulton, a township in the parish of Rothwell, in the West Riding of Yorkshire. His grandfather had suffered in person and estate in the royal cause, and the family were in consequence in reduced circumstances. Bentley's mother, the daughter of a stonemason in Oulton, was a woman of excellent understanding and some education, as she was able to give her son his first lessons in Latin. From the grammar school of Wakefield Richard Bentley passed to St John's College, Cambridge, being admitted subsizar in 1676. He afterwards obtained a scholarship, but never succeeded to a fellowship, being appointed by his college, before he was twenty-one, head-master of Spalding grammar school. In this post he did not remain long, being selected by Dr Stillingfleet, Dean of St Paul's, to be domestic tutor to his son. This appointment introduced Bentley at once to the society of the most eminent men of the day, threw open to him the best private library in England, and brought him into familiar intercourse with Dean Stillingfleet, a man of sound understanding, who had not shrunk from exploring some of the more solid and abstruse parts of ancient learning. The example of such a patron seconding his natural inclinations drew Bentley into a course of thorough reading, which, however, took a philological rather than a philosophical direction. The six years which he passed in Stillingfleet's family were employed, with the restless energy characteristic of the man, in exhausting the remains of the Greek and Latin writers, and laying up those stores of knowledge upon which he afterwards drew for his various occasions.

In 1689 Stillingfleet became bishop of Worcester, and Bentley's pupil went to reside at Oxford in Wadham College, accompanied by his tutor. Bentley's introductions, and his own merits, placed him at once on a footing of intimacy with the most distinguished scholars in the university -Mill, Hody, Edward Bernard. Here he revelled in the MS. treasures of the Bodleian, Corpus, and other college libraries. He projected, and occupied himself with collections for, vast literary schemes. Among these are specially mentioned a *corpus* of the fragments of the Greek poets, and an edition of the Greek lexicographers. But his first publication was in connection with a writer of much inferior note. The Oxford press was about bringing out an edition (the *editio princeps*) of the *Chronicle of John Malalas*, from the unique MS. in the Bodleian; and the editor, Dr Mill, had requested Bentley to look through the sheets, and make any remarks on the text. This originated Bentley's *Epistola ad Millium*, which occupies less than one hundred pages at the end of the Oxford *Malalas* (*e Theatro Sheldoniano*, 1691, 8vo). This short tractate at once placed Bentley at the head of all living English scholars. The ease with which, by a stroke of the pen, he restores passages which had been left in hopeless corruption by the editors of the *Chronicle*, the certainty of the emendation, and the command over the relevant material, are in a style totally different from the careful and laborious learning of Hody, Mill, or Chilmead. To the small circle of classical students it was at once apparent that there had arisen in England a critic, whose attainments were not to be measured by the ordinary academical standard, but whom these few pages had sufficed to place by the side of the great Grecians of a former age. Unfortunately this mastery over critical science was accompanied by a tone of self-assertion and presumptuous confidence, which not only checked admiration, but was calculated to rouse enmity. Dr Monk, indeed, Bentley's biographer, has charged him with an indecorum of which he was not guilty. "In one place," writes Dr Monk, "he accosts Dr Mill as ὦ Ἰαννίδιον, an indecorum which neither the familiarity of friendship, nor the licence of a dead language, can justify towards the dignified head of a house." But the object of Bentley's apostrophe is not his correspondent Dr Mill, but his author John Malalas, whom in another place he playfully appeals to as "Syrisce." From this publication, however, dates the origin of those mixed feelings of admiration and repugnance which Bentley through his whole career continued to excite among his contemporaries.

In 1690 Bentley had taken deacon's orders in the Established Church. In 1692 he was nominated first Boyle lecturer, a nomination which was repeated in 1694. He was offered the appointment a third time in 1695, but declined it, being by that time involved in too many other undertakings. In these first series of lectures he endeavours to present the Newtonian physics in a popular form, and to frame them into a proof of the existence of an intelligent Creator. The second series, preached in 1694, has not been published, and is believed to be lost. Scarcely was Bentley in priest's orders before he was preferred to a prebendal stall in Worcester cathedral. And, in 1693, the keepership of the royal library becoming vacant by the death of Henri de Justel, great efforts were made by his friends to obtain the place for Bentley. But, though there was a High Church candidate (Edmund Gibson) backed by the archbishops, the court interest prevailed, and the place was given to Mr Thynne. Mr Thynne, however, wanted only the salary and not the office, and was prevailed on to cede the place to Bentley for an annuity of £130 for life, the whole emoluments being but £200 and apartments in St James's Palace. To these preferments were added, in 1695, a royal chaplaincy, and the living of Hartlebury. He was also about the same time elected a fellow of the Royal Society. And the recognition of Continental scholars came in the shape of a dedication, by Grævius (John George), prefixed to a dissertation of Albert Rubens, *De vita Th. Mallii*, published at Utrecht in 1694.

While these distinctions were being accumulated upon Bentley, his energy was making itself felt in many and various directions. His first care was the royal library, the queen's library, as it was commonly called. He made great efforts to retrieve this collection from the dilapidated condition into which it had been allowed to fall. He employed the mediation of the earl of Marlborough to beg the grant of some additional rooms in the palace for the books. The rooms were granted, but Marlborough characteristically kept them for himself. Bentley enforced the law against the publishers, and thus added to the library nearly 1000 volumes which had been neglected to be delivered. He was commissioned by the University of Cambridge to obtain Greek and Latin founts for their classical books, and he had accordingly cast, in Holland, those beautiful types which appear in the Cambridge books of that date. He assisted Evelyn in his *Numismata*. All Bentley's literary appearances at this time were of this accidental character. We do not find him settling down to the steady execution of any of the great projects with which he had started. He designed, indeed, in 1694, an edition of Philostratus, but easily abandoned it to Olearius, "to the joy," says F. A. Wolf, "of Olearius and of no one else." He supplied Grævius with collations of Cicero, and Joshua Barnes with a warning as to the spuriousness of the *Epistles of Euripides*, which was thrown away upon that blunderer, who printed the epistles and declared that no one could doubt their genuineness but a man "perfrictæ

frontis aut judicii imminuti." Bentley supplied to Græviu's *Callimachus* a masterly collection of the fragments.

The *Dissertation on the Epistles of Phalaris*, the work on which Bentley's fame in great part rests, originated in the same casual way. Wotton being about to bring out a second edition of his book on *Ancient and Modern Learning*, claimed of Bentley the fulfilment of an old promise to write a paper exposing the spuriousness of the *Epistles of Phalaris*. This paper was resented as an insult by the Christchurch editor of Phalaris, Hon. Charles Boyle, afterwards earl of Orrery. Assisted by his college friends, Boyle wrote a reply, "a tissue," says Mr Dyce, "of superficial learning, ingenious sophistry, dexterous malice, and happy raillery." The reply was hailed by the public as crushing, and went immediately into a second edition. It was incumbent on Bentley to rejoin. This he did, in what Porson styles "that immortal dissertation," to which no answer was, or could be, given.

In the year 1700, Bentley, then in his 38th year, received that main preferment which, says De Quincey, "was at once his reward and his scourge for the rest of his life." The six commissioners of ecclesiastical patronage unanimously recommended Bentley to the Crown for the headship of Trinity College.

Trinity College, the most splendid foundation in the University of Cambridge, and in the scientific and literary reputation of its fellows the most eminent society in either university, had, in 1700, greatly fallen from its high estate. It was not that it was more degraded than the other colleges, but its former lustre made the abuse of endowments in its case more conspicuous. The eclipse had taken place during the reaction which followed 1660, and was owing to causes which were not peculiar to Trinity, but which influenced the nation at large. The names of Pearson and Barrow, and, greater than either, that of Newton, adorn the college annals of this period. But these were quite exceptional men. They had not inspired the rank and file of fellows of Trinity with any of their own love for learning or science. Indolent and easy-going clerics, without duties, without a pursuit, or any consciousness of the obligation of endowments, they haunted the college for the pleasant life and the good things they found there, creating sinecure offices in each other's favour, jobbing the scholarships, and making the audits mutually pleasant. Any excuse served for a banquet at the cost of "the house," and the celibate imposed by the statutes was made as tolerable as the decorum of a respectable position permitted. To such a society Bentley came, obnoxious as a Johnian and an intruder, unwelcome as a man of learning, whose interests lay outside the walls of the college. Bentley replied to their concealed dislike with open contempt, and proceeded to ride roughshod over their little arrangements. He inaugurated many beneficial reforms in college usages and discipline, executed extensive improvements in the buildings, and generally used his eminent station for the promotion of the interests of learning, both in the college and in the university. But this noble energy was attended by a domineering temper, an overweening contempt for the feelings, and even for the rights, of others, and an unscrupulous use of means when a good end could be obtained. Bentley, at the summit of classical learning, disdained to associate with men whom he regarded as illiterate priests. He treated them with contumely, while he was diverting their income to public purposes. The continued drain upon their purses—on one occasion the whole dividend of the year was absorbed by the rebuilding of the chapel—was the grievance which at last roused the fellows to make a resolute stand. After ten years of stubborn, but ineffectual resistance within the college, they had recourse, in 1710, to the last remedy—an appeal to the visitor. Their petition is an ill-drawn invective, full of general complaints, and not alleging any special delinquency. Bentley's reply (*The Present State of Trinity College, &c.*, 8vo, Lond. 1710) is in his most crushing style. The fellows amended their position, and put in a fresh charge, in which they articled fifty-four separate breaches of the statutes as having been committed by the master. Bentley, called upon to answer, demurred to the bishop of Ely's jurisdiction, alleging that the Crown was visitor. He backed his application by a dedication of his Horace to the lord treasurer (Harley). The Crown lawyers decided the point against him; the case was heard, and a sentence of ejection from the mastership ordered to be drawn up, but before it was executed the bishop of Ely died, and the process lapsed.

This process, though it had lasted nearly five years, was only a prologue to the great feud, the whole duration of which was twenty-nine years. Space will not allow of its vicissitudes being here followed. It must suffice to say that Bentley was sentenced by the bishop of Ely (Greene) to be ejected from the mastership, and by Convocation to be stripped of his degrees, and that he foiled both the visitor and the university.

Bentley survived the extinction of this thirty years' war, two years. Surrounded by his grandchildren, he experienced the joint pressure of age and infirmity as lightly as is consistent with the lot of humanity. He continued to amuse himself with reading; and though nearly confined to his arm-chair, was able to enjoy the society of his friends, and several rising scholars, Maitland, John Taylor, his nephews Richard and Thomas Bentley, with whom he discussed classical subjects. He was accustomed to say that he should live to be 80, adding that a life of that duration was long enough to read everything worth reading. He fulfilled his own prediction, dying, of a pleurisy, 14th July 1742, when he was a few months over 80. Though accused by his enemies of being grasping, he left not more than £5000 behind him. A few Greek MSS., brought from Mount Athos, he left to the college library; his books and papers to his nephew, Richard Bentley. Richard, who was a fellow of Trinity, at his death in 1786, left the papers to the college library. The books were acquired, by purchase, by the British Museum.

Of his personal habits some anecdotes are related by his grandson, Richard Cumberland, in vol. i. of his *Memoirs* (Lond. 1807). The hat of formidable dimensions, which he always wore during reading to shade his eyes, and his preference of port to claret, are traits embodied in Pope's caricature (*Dunciad*, b. 4), which bears in other respects little resemblance to the original. He did not take up the habit of smoking till he was 70. He held the archdeaconry of Ely with two livings, but never obtained higher preference in the church. He was offered the (then poor) bishopric of Bristol, but refused it, and being asked what preferment he would consider worth his acceptance, replied, "That which would leave him no reason to wish for a removal."

Dr Bentley married, in 1701, Joanna, daughter of Sir John Bernard of Brompton. Their union lasted forty years. Mrs Bentley died in 1740, leaving a son, Richard, and two daughters, one of whom married, in 1728, Mr Denison Cumberland, grandson of Richard Cumberland, bishop of Peterborough, and father of Richard Cumberland the dramatic author.

The *Life of Richard Bentley*, by Bishop Monk (4to, Lond. 1830; 2d ed., 2 vols. 8vo, 1833), gives in full detail an interesting account of the Trinity College feud, and the other incidents of his hero's life. But, though himself a Greek scholar of celebrity and an editor of Euripides, Dr Monk appears to have had but an imperfect compre-

hension of the consummate genius and vast acquirements of the subject of his biography. He regrets that Bentley wasted his time upon conjectural criticism, instead of applying himself to the deistical controversy. The *Remarks upon a late Discourse of Freethinking*, by Phileleutherus Lipsiensis, 8vo, 1713, to which Dr Monk alludes, is indeed a very characteristic piece of writing; but it gives no more idea of what Bentley was as a master of ancient learning than does his pamphlet, *The Present State of Trinity College*, quoted before. Indeed, of all Bentley's publications there is not one which can be taken as an adequate sample of the critic, as a work at once monumental and characteristic. Bentley is most imperfectly represented by any one of his books. They have all the same occasional stamp. This is the case not only with the most popular of these, the *Dissertation on Phalaris*. The *Horatius* of 1712 was brought out to propitiate public opinion at a critical period of the struggle with the fellows of Trinity; the proposals for a recension of the New Testament text, 1720, had a similar origin; the *Terentius* of 1725 was occasioned by his resentment of Hare's conduct. The *Milton* was undertaken at the request of Queen Caroline, but also at an anxious conjuncture of the great quarrel. Nearly all his lesser performances were called forth by friends invoking his aid for their own schemes. What he wrote, he wrote with rapidity, rather with precipitation. If we try to form our idea of the man, not from this or that extempore effusion, but from all that he did or was, we shall find that Bentley was the first, perhaps the only Englishman who can be ranked with the great heroes of classical learning. Before him we have only Selden to name, or, in a more restricted field, Gataker and Pearson. But Selden, with stupendous learning, wanted that which Bentley shared with Scaliger or Wolf, the freshness of original genius and confident mastery over the whole region of his knowledge. "Bentley is not," says Mahly, "one among the great classical scholars, but he inaugurates a new era of the art of criticism. He opened a new path. With him criticism attained its majority. When scholars had hitherto offered suggestions and conjectures, Bentley, with unlimited control over the whole material of learning, gave decisions." The modern German school of philology, usually so unjust to foreigners, yet does ungrudging homage to the genius of this one Englishman. Bentley, says Bunsen, "was the founder of historical philology." And Bernays says of his corrections of the *Tristia*, "corruptions which had hitherto defied every attempt even of the mightiest, were removed by a touch of the fingers of this British Samson." The English school of Hellenists, by which the 18th century was distinguished, and which contains the names of Dawes, Markland, Taylor, Toup, Tyrwhitt, Porson, Dobree, Kidd, and Monk, was the creation of Bentley. And even the Dutch school of the same period, though the outcome of a native tradition, was in no small degree stimulated and directed by Bentley's example. Ruhnken has recorded the powerful effect produced upon the young Hemsterhuys by Bentley's letter to him on the occasion of his *Pollux;* at first humiliated to despair by the revelation to him of his own ignorance; then stimulated to higher effort by the consideration that commendation from such a man was not words of mere compliment.

Bentley was a source of inspiration to a following generation of scholars. Himself, he sprang from the earth without forerunners, without antecedents. Self-taught, he created his own science. It was his misfortune that there was no contemporary guild of learning in England by which his power could be measured, and his eccentricities checked. In the *Phalaris* controversy his academical adversaries had not sufficient knowledge to know how absolute their defeat was. Garth's couplet—

"So diamonds take a lustre from their foil,
And to a Bentley 'tis we owe a Boyle"—

expressed the belief of the wits, or literary world, of the time. It was not only that he had to live with inferiors, and to waste his energy in a struggle forced upon him by the necessities of his official position, but the wholesome stimulus of competition and the encouragement of a sympathetic circle were wanting. In a university where the instruction of youth, or the religious controversy of the day, were the only known occupations, Bentley was an isolated phenomenon, and we can hardly wonder that he should have flagged in his literary exertions after his appointment to the mastership of Trinity. All his vast acquisitions and all his original views seem to have been obtained before 1700. After this period he acquired little, and made only spasmodic efforts—the *Horace*, the *Terence*, and the *Milton*. The prolonged mental concentration, and mature meditation, of which alone a great work can be born, were wanting to him.

BENZOIC ACID, an organic acid present in large quantity in gum benzoin, and found also in dragon's blood (the resin of *Calamus Draco*) and some allied substances. It is, besides, prepared by numerous reactions from organic substances, being now largely made from naphthalin, one of the products of the distillation of coal tar. Benzoic acid is extracted from gum benzoin by the process of sublimation. The resin, coarsely powdered, is submitted to a heat of 300° Fahr. in a close vessel, by which the acid is expelled and may be condensed in receivers. By the sublimation process the acid carries away with it a small portion of essential oil, which gives its peculiar sweet odour to sublimed benzoic acid. It may also be separated from gum benzoin by boiling the powdered gum in lime, filtering off the compound of resin and lime, and concentrating the remaining solution of benzoate of calcium, from which benzoic acid is precipitated by hydrochloric acid. The benzoic acid may then be purified by sublimation, but thus prepared it is destitute of odour. It crystallizes into beautiful white silky flexible needles, and yields on heating an acrid, irritating vapour which excites coughing. It is distinguished from the closely allied substance, cinnamic acid, by withstanding the action of boiling dilute nitric acid, which changes the other into bitter almond oil, the hydride of benzoyl. Benzoic acid is rarely employed in medicine alone, but in composition as benzoate of ammonia it acts as a stimulant of mucous membranes, and is occasionally given in chronic bronchial affections. It is an

ingredient in some officinal tinctures, such as the compound tincture of camphor, and ammoniated tincture of opium.

BENZOIN, GUM, sometimes called GUM BENJAMIN, a fragrant gum-resin obtained from *Styrax Benzoin*, a tree of considerable size, a native of Sumatra and Java, and introduced into Siam, Borneo, &c. The gum-resin is obtained by making incisions in the bark of trees after they have attained six years of age, when the benzoin exudes, and after hardening in the air is carefully scraped off with a knife. A tree produces on an average about 3 lb annually for 10 or 12 years. The produce of the first three years is known as "head" benzoin, and is esteemed the finest and most valuable; that produced in later years goes by the name of "belly" benzoin; and after the trees are cut down a small quantity of a dark-coloured and very inferior quality is obtained, which is called "foot" benzoin. In commerce the gum-resin is distinguished as Siam or Sumatra benzoin, according to the localities from which it is derived. Siam benzoin is generally regarded as the best, and of it two varieties are distinguished. The finest quality is Siam benzoin "in tear," it being in small flattened drops, from the size of an almond kernel downwards. "Lump" Siam benzoin consists of agglutinated masses of such tears, or of tears imbedded in a darker coloured resinous matrix. Tear benzoin varies in colour from a pale yellow to a reddish-brown colour, and lump benzoin has a conglomerate-like structure from the dissemination of almond-shaped tears throughout the substance. Sumatra benzoin has neither so strong nor so agreeable an odour as that of Siam, but the finest qualities are not found in the English market, being bought up for use in the religious rites of the Greek Church in Russia. Sumatra benzoin occurs in larger rectangular masses of a greyish tint, with few large tears in it, but containing small white opaque pieces, with chips of wood and other impurities, in a translucent matrix. Benzoin is composed of a mixture of three resins, distinguished by their behaviour towards solvents, and of benzoic acid, with sometimes cinnamic acid in addition; in some specimens of Sumatra benzoin cinnamic acid has been found entirely replacing benzoic acid. Usually benzoin contains from 12 to 18 per cent. of benzoic acid, the opaque white portions containing less than the brown resinous substance. It also contains traces of a highly odorous essential oil, like styrol, the aromatic oil present in storax. The quantity of benzoin exported from Sumatra in 1871 was about 16,000 cwt., while Siam sent out only 405 cwt., but very great quantities are used as incense in the religious ceremonies of the East, which indeed is the principal object for which it is brought into the commerce of Western nations. In medicine benzoin is seldom administered except as an adjunct to pectoral medicines. A compound tincture of benzoin is applied to flabby ulcers, and to excised wounds after the edges have been brought together. In these connections benzoin has a popular reputation under the name of Friars' or Monks' Balsam, which is a compound tincture of benzoin, and it forms an ingredient in court or black sticking-plaster. Benzoin diminishes the tendency towards rancidity in fats, a circumstance turned to account in the *Adeps benzoatus* of pharmacy.

BÉRANGER, PIERRE JEAN DE, the national song-writer of France, was born at Paris on the 19th August 1780. The aristocratic particle before the name was a piece of groundless vanity on the part of his father, which the poet found useful as a distinction. He was descended, in truth, from a country innkeeper on the one side, and, on the other, from a tailor in the Rue Montorgueil Of education, in the narrower sense, he had but little From the roof of his first school he beheld the capture of the Bastille, and this stirring memory was all that he acquired. Later on he passed some time in a school at Péronne, founded by one Bellenglise on the principles of Rousseau, where the boys were formed into clubs and regiments, and taught to play solemnly at politics and war. Béranger was president of the club, made speeches before such members of Convention as passed through Péronne, and drew up addresses to Tallien or Robespierre at Paris. In the meanwhile he learned neither Greek nor Latin—not even French, it would appear; for it was after he left school, from the printer Laisney, that he acquired the elements of grammar. His true education was of another sort. In his childhood, shy, sickly, and skilful with his hands, as he sat at home alone to carve cherry stones, he was already forming for himself those habits of retirement and patient elaboration which influenced the whole tenor of his life and the character of all that he wrote. At Péronne he learned of his good aunt to be a stout republican; and from the doorstep of her inn, on quiet evenings, he would listen to the thunder of the guns before Valenciennes, and fortify himself in his passionate love of France and distaste for all things foreign. Although he could never read Horace save in a translation, he had been educated on *Telemaque*, Racine, and the dramas of Voltaire, and taught, from a child, in the tradition of all that is highest and most correct in French.

After serving his aunt for some time in the capacity of waiter, and passing some time also in the printing office of one Laisney, he was taken to Paris by his father. Here he saw much low speculation and many low royalist intrigues. In 1802, in consequence of a distressing quarrel, he left his father and began life for himself in the garret of his ever memorable song. For two years he did literary hackwork, when he could get it, and wrote pastorals, epics, and all manner of ambitious failures. At the end of that period (1804) he wrote to Lucien Bonaparte, enclosing some of these attempts. He was then in bad health, and in the last state of misery. His watch was pledged. His wardrobe consisted of one pair of boots, one greatcoat, one pair of trousers with a hole in the knee, and "three bad shirts which a friendly hand wearied itself in endeavouring to mend." The friendly hand was that of Judith Frère, with whom he had been already more or less acquainted since 1796, and who continued to be his faithful companion until her death, three months before his own, in 1857. She must not be confounded with the Lisette of the songs; the pieces addressed to her (*La Bonne Vieille*, *Maudit Printemps*, &c.) are in a very different vein. Lucien Bonaparte interested himself in the young poet, transferred to him his own pension of 1000 francs from the Institute, and set him to work on a *Death of Nero*. Five years later, through the same patronage, although indirectly, Béranger became a clerk in the university at a salary of another thousand.

Meanwhile he had written many songs for convivial occasions, and "to console himself under all misfortunes;" some, according to M. Boiteau, had been already published by his father; but he set no great store on them himself and it was only in 1812, while watching by the sick-bed of a friend, that it occurred to him to write down the best he could remember. Next year he was elected to the *Caveau Moderne*, and his reputation as a song-writer began to spread. Manuscript copies of *Les Gueux*, *Le Sénateur*, above all of *Le Roi d'Yvetot*, a satire against Napoleon, whom he was to magnify so much in the sequel, passed from hand to hand with acclamation. It was thus that all his best works went abroad; one man sang them to another over all the land of France. He was the only poet of modern times who could altogether have dispensed with printing.

His first collection escaped censure. "We must pardon

many things to the author of the *Roi d'Yvetot*," said Louis XVIII. The second (1821) was more daring. The apathy of the Liberal camp, he says, had convinced him of the need for some bugle call of awakening. This publication lost him his situation in the university, and subjected him to a trial, a fine of 500 francs, and an imprisonment of three months. Imprisonment was a small affair for Béranger. At Sainte Pélagie he occupied a room (it had just been quitted by Paul Louis Courier), warm, well-furnished, and preferable in every way to his own poor lodging, where the water froze on winter nights. He adds, on the occasion of his second imprisonment, that he found a certain charm in this quiet, claustral existence, with its regular hours and long evenings alone over the fire. This second imprisonment of nine months, together with a fine and expenses amounting to 1100 francs, followed on the appearance of his fourth collection The Government proposed through Laffitte that, if he would submit to judgment without appearing or making defences, he should only be condemned in the smallest penalty. But his public spirit made him refuse the proposal; and he would not even ask permission to pass his term of imprisonment in a *Maison de Santé*, although his health was more than usually feeble at the time "When you have taken your stand in a contest with Government, it seems to me," he wrote, "ridiculous to complain of the blows it inflicts on you, and impolitic to furnish it with any occasion of generosity." His first thought in La Force was to alleviate the condition of the other prisoners.

In the revolution of July he took no inconsiderable part. Copies of his song, *Le Vieux Drapeau*, were served out to the insurgent crowd. He had been for long the intimate friend and adviser of the leading men; and during the decisive week his counsels went a good way towards shaping the ultimate result. "As for the republic, that dream of my whole life," he wrote in 1831, "I did not wish it should be given to us a second time unripe." Louis Philippe, hearing how much the song-writer had done towards his elevation, expressed a wish to see and speak with him; but Béranger refused to present himself at court, and used his favour only to ask a place for a friend, and a pension for Rouget de l'Isle, author of the famous *Marseillaise*, who was now old and poor, and whom he had been already succouring for five years.

In 1848, in spite of every possible expression of his reluctance, he was elected to the assembly, and that by so large a number of votes (4471) that he felt himself obliged to accept the office. Not long afterwards, and with great difficulty, he obtained leave to resign. This was the last public event of Béranger's life He continued to polish his songs in retirement, visited by nearly all the famous men of France. He numbered among his friends Chateaubriand, Thiers, Laffitte, Michelet, Lamennais, Mignet. Nothing could exceed the amiability of his private character; so poor a man has rarely been so rich in good actions; he was always ready to receive help from his friends when he was in need, and always forward to help others. His correspondence is full of wisdom and kindness, with a smack of Montaigne, and now and then a vein of pleasantry that will remind the English reader of Charles Lamb. He occupied some of his leisure in preparing his own memoirs, and a certain treatise on *Social and Political Morality*, intended for the people, a work he had much at heart, but judged at last to be beyond his strength. He died on the 16th July 1857. It was feared that his funeral would be the signal for some political disturbance; but the Government took immediate measures, and all went quietly. The streets of Paris were lined with soldiers and full of townsfolk, silent and uncovered. From time to time cries arose:—"*Honneur, Honneur à Béranger!*"

The songs of Béranger would scarcely be called songs in England. They are elaborate, written in a clear and sparkling style, full of wit and incision. It is not so much for any lyrical flow as for the happy turn of the phrase that they claim superiority. Whether the subject be gay or serious, light or passionate, the medium remains untroubled. The special merits of the songs are merits to be looked for rather in English prose than in English verse. He worked deliberately, never wrote more than fifteen songs a year and often less, and was so fastidious that he has not preserved a quarter of what he finished. "I am a good little bit of a poet," he says himself, "clever in the craft, and a conscientious worker, to whom old airs and a modest choice of subjects (*le coin ou je me suis confiné*) have brought some success." Nevertheless, he makes a figure of importance in literary history. When he first began to cultivate the *chanson*, this minor form lay under some contempt, and was restricted to slight subjects and a humorous guise of treatment. Gradually he filled these little chiselled toys of verbal perfection with ever more and more of sentiment. From a date comparatively early he had determined to sing for the people. It was for this reason that he fled, as far as possible, the houses of his influential friends, and came back gladly to the garret and the street corner. Thus it was, also, that he came to acknowledge obligations to Emile Debraux, who had often stood between him and the masses as interpreter, and given him the key-note of the popular humour. Now, he had observed in the songs of sailors, and all who labour, a prevailing tone of sadness; and so, as he grew more masterful in this sort of expression, he sought more and more after what is deep, serious, and constant in the thoughts of common men. The evolution was slow; and we can see in his own works examples of every stage, from that of witty indifference in fifty pieces of the first collection, to that of grave and even tragic feeling in *Les Souvenirs du Peuple* or *Le Vieux Vagabond*. And this innovation involved another, which was as a sort of prelude to the great romantic movement. For the *chanson*, as he says himself, opened up to him a path in which his genius could develop itself at ease; he escaped, by this literary postern, from strict academical requirements, and had at his disposal the whole dictionary, four-fifths of which, according to La Harpe, were forbidden to the use of more regular and pretentious poetry. If he still kept some of the old vocabulary, some of the old imagery, he was yet accustoming people to hear moving subjects treated in a manner more free and simple than heretofore; so that his was a sort of conservative reform, preceding the violent revolution of Victor Hugo and his army of uncompromising romantics. He seems himself to have had glimmerings of some such idea; but he withheld his full approval from the new movement on two grounds:—first, because the romantic school misused somewhat brutally the delicate organism of the French language; and second, as he wrote to Sainte-Beuve in 1832, because they adopted the motto of "Art for art," and set no object of public usefulness before them as they wrote. For himself (and this is the third point of importance) he had a strong sense of political responsibility. Public interest took a far higher place in his estimation than any private passion or favour. He had little toleration for those erotic poets who sing their own loves and not the common sorrows of mankind, "who forget," to quote his own words, "forget beside their mistress those who labour before the Lord." Hence it is that so many of his pieces are political, and so many, in the later times at least, inspired with a socialistic spirit of indignation and revolt. It is by this socialism that he becomes truly modern, and touches hands with Burns.

The following books may be consulted:—*Ma Biographie* (his own memoirs); *Vie de Béranger*, by Paul Boiteau, 1861; *Correspondance de Béranger*, edited by Paul Boiteau, 4 vols., 1860; *Béranger et Lamennais* (by Napoléon Peyrat), 1857; *Quarante-Cinq lettres de Béranger publiées par Madame Louise Colet* (almost worthless), 1857; *Béranger ses amis, ses ennemis, et ses critiques*, by A. Arnould, 2 vols., 1864; J Janin, *Béranger et son Temps*, 2 vols., 1866; also Sainte-Beuve's *Portraits Contemporains*, vol. i. (R. L S.)

BERAR, a province of British India, forming a Commissionership, is situated between 19° 30′ and 21° 46′ N. lat., and 76° and 79° 13′ E. long. Area, about 17,500 square miles; population, 2¼ millions. The province consists of the districts assigned to the British Government by his Highness the Nizám of Haidarábád, under the treaties of 1853 and 1861. These districts are Amráotí, Elichpur, Wún, Akolá, Buldáná, and Básim. Berar province is bounded on the N. and E. by the Central Provinces, on the S. by the Nizám's dominions, and on the W. by the Nizám's territory, the Bombay district of Khandesh, and by the Central Provinces. The Ajantá range intersects the whole province from W. to E., and divides it into two distinct sections—the Payanghát or lowland country, bounded on the N. by

the Gáwilgarh range of the Sátpurá hills, which form the northern boundary between Berar and the Central Provinces, and on the S. by the Ajantá range, and the Bálághát or upland country of the Ajantá hills, occupying the whole southern part of the province. The Payangbát is a wide valley running up eastward between the Ajantá range and the Gáwilgarh hills, from 40 to 50 miles in breadth. This tract contains all the best land in Berar, it is full of deep, rich, black alluvial soil, called *regár*, of almost inexhaustible fertility, and it undulates just enough to maintain a natural system of drainage. Here and there are barren tracts where the hills jut out far into the plain, covered with stones and scrub jungle, or where a few isolated flat-topped hills occur. There is nothing picturesque about this broad strip of alluvial country, it is destitute of trees except near the villages close under the hills; and apart from the Púrná, which intersects it from east to west, it has hardly a perennial stream. In the early autumn it is one sheet of cultivation, but after the beginning of the hot season, when the crops have been gathered, its monotonous plain is relieved by neither verdure, shade, nor water. The aspect of the country above the passes which lead to the Bálághát is quite different. The trees are finer and the groves more frequent than in the valley below; water is more plentiful and nearer to the surface. The highlands fall southwards towards the Nizám's country by a gradual series of ridges or steppes. The principal rivers of the province are the Taptí, which forms a portion of its north-western boundary; the Púrná, which intersects the valley of the Payanghát; the Wardhá, forming the whole western boundary line; and the Páin-gangá, marking the southern boundary for nearly its whole distance. The only natural lake is the Salt Lake of Sunár. There are no large tanks or artificial reservoirs.

The total area of the province in 1869-70 was returned at between 17,000 and 18,000 square miles, of which about one-half is cultivated, one-fourth cultivable but not cultivated, and the remaining one-fourth uncultivable waste. The great crops are cotton of a superior quality, and *joár* or millet. The acreage under the different crops in 1869-70 is thus returned—*Joár*, 1,812,698 acres; cotton, 1,409,430; wheat, 478,438; pulses, 493,009; *bajrá*, 117,273; rice, 44,793; linseed, 61,394; hemp, 8978; *kardi*, 57,192; tobacco, 32,284; castor oil, 2605; sugar cane, 7947; opium, 247; other crops, 829,992; total, 5,356,275 acres, or 8369 square miles. The uncultivated products consist of dyes, gums, fruits and roots of various trees and creepers, honey and beeswax, and jungle fibres. The land settlement of the province is now being made for a period of thirty years, based upon the Bombay system of survey and settlement according to fields. Manufactures are very few, and consist principally of cotton cloth, mostly of coarse quality, stout carpets, saddlery, and a little silk weaving. In 1869-70 the total value of the imports was returned at £7,350,085, and the exports at £5,755,399. For internal communication six first-class roads have been constructed out of the general revenues of the province:—(1), From Amráotí to Elichpur, 31 miles; (2), from Badnerá to Morsi, 38½; (3), from Karinjá to Murtizápur, 21; (4), from Badnerá to Amráotí, 5; (5), from Akolá to Básim, 50; (6), from Akolá to Akot, 31 miles. The Nágpur branch of the Great Indian Peninsular Railway traverses the province from east to west for about 150 miles, with short off-shoots to the great cotton marts of Khamgáon and Amráotí.

The census of 1867 returned the total population of Berar province at 2,231,565 souls, dwelling in 495,760 houses, comprising 5694 towns and villages; average density of population, 128 per square mile; average number of persons per house, 4·5; proportion of males in total population, 51·7 per cent. Classified according to religion, the Hindus number 1,912,561, or 85·70 per cent. of the total population; Mahometans, 154,951, or 6·94 per cent.; aborigines, 163,059, or 7·36 per cent.; Christians, 903; Parsís, 75; and Jews, 16. The Mahometan population of the province is descended from the men who originally accompanied from the north the Musalmán invaders of the Deccan. Among the aboriginal tribes, the most numerous are the Gonds, Ands, Korkus, Kolis, and Koláms. The principal towns in the province are—(1.) Elichpur, the capital of the old kingdom, and still the most populous town, although not a place of any commercial importance, population 27,782; (2.) Amráotí, the richest town in the province, and a rising and flourishing seat of commerce, pop. 23,410; (3.) Akolá, pop. 12,236; (4.) Akot, a large cotton mart, pop. 14,606; (5.) Karinjá, pop. 11,750; (6.) Khamgáon, a large and prosperous cotton mart, pop. 9432.

The total imperial revenue of Berar province in 1869-70 amounted to £704,109, of which the land revenue gave £457,348; excise, £114,513; salt wells, £650; miscellaneous, £39,413; stamps, £45,947; forests, £18,462; and customs (salt), £27,780. Local funds and cesses amounted to £132,229, or a total revenue from imperial and local sources for the province of £836,338. For the protection of person and property Berar province contains 67 police stations, with 61 outposts—total strength of regular police, 2613 of all ranks, exclusive of the village watch. The only troops located in the province are those of the Haidarábád contingent. At Elichpur a regiment of infantry with a detachment of cavalry and a battery of artillery is stationed; infantry detachments are also stationed at Amráoti and Akolá. The provision for education consisted in March 1870 of 341 schools, attended by 14,898 pupils. Of these 2 are high schools, one at Akolá and one at Amráotí, with 217 pupils; 44 middle-class schools with 3747 pupils; 267 primary schools with 10,148 pupils; 27 female schools with 730 pupils; and 1 Normal school for the training of masters.

The climate of Berar differs very little from that of the Deccan generally, except that in the Payanghát valley the hot weather is exceptionally severe. Here the freshness of the cold season vanishes after the crops have been taken off the ground, but the heat does not very sensibly increase until the end of March. From May 1st, until about the middle of June when the rain sets in, the sun is very powerful, but without the scorching winds of upper India. The nights are comparatively cool. During the rains the air is moist and cool. In the Bálághát country above the Ajantá hills the thermometer always stands much lower than in the valley. The average rainfall for the whole province is said to be about 27 inches in the valley, and above 30 inches in the Bálághát highlands. In 1869 the rainfall registered in each of the six districts averaged 33 inches for the whole province. The average mean temperature registered at Akolá in the same year was nearly 81° Fahr.

The early history of Berar belongs to that of the Deccan. The province suffered repeated invasions of Mahometans from the north, and on the collapse of the Báhmani dynasty in 1526, Berar formed one of the five kingdoms under independent Mahometan princes, into which the Deccan split up. In the beginning of the seventeenth century the province was invaded by Prince Murad Mirza, son of the Emperor Akbar, and annexed to the Dehli empire. It did not long enjoy the blessings of tranquillity, for on the rise of the Marhattá power about 1650, the province became a favourite field of plunder. In 1671 the Marhattá general, Pratáp Ráo, extended his ravages as far east as Karinjá, and exacted from the village officers a pledge to pay *chauth*. In 1704 things had reached their worst; the Marhattás swarmed through Berar "like ants or locusts," and laid bare whole districts. They were expelled in 1704 by Zulfikár Khan, one of Aurangzeb's best generals, but they returned incessantly, levying black-mail in the shape of *chauth* and *sardeshmukhí*, with the alternative of fire and sword. Upon the death of Aurang zeb the Marhattás consolidated their predominance in Berar, and in 1817 their demand for *chauth*, or a fourth, and *sardeshmukhí*, or a tenth of the revenue of the province, was conceded by the governor. But in 1720-24 the viceroy of the Deccan, under the title of Nizám-ul-mulk, gained his independence by a series of victories over the imperial generals, and from that time till its cession to England in 1853, Berar was always nominally subject to the Haidarábád dynasty. The Mahrattá rulers posted their officers all over the province, they occupied it with their troops, they collected more than half the revenue, and they fought among themselves for possession of the right to collect; but, with the exception of a few *parganás* ceded to the Peshwá, the Nizám maintained his title as *de jure* sovereign of the country, and it was always admitted by the Marhattás. In the Marhattá war of 1803, the British under General Wellesley, afterwards the duke of Wellington, assisted by the Nizám, crushed the Marhattá power in this part of the country, by utterly defeating them at Argáon on the 28th November 1803, and a few days afterwards at Gáwilgarh. On the 19th December

1803 the Marhattá chief signed a treaty, in which he resigned all claim to territory and revenue west of the Wardhá, but retained Narnálá and Gáwilgarh in his possession. By this treaty the whole of Berar was made over in perpetual sovereignty to the Nizám. From that time till 1848 the history of the province consists of a long list of internal dissensions and civil wars. These troubles reduced the state to the verge of bankruptcy. The pay of the Nizám's irregular force, maintained under the treaty of 1800, fell into arrears, and had to be advanced by the British Government There were also other unsatisfied claims of the Government on the Nizám, and in 1853 his whole debt amounted to £450,000. Accordingly, in that year a new treaty was concluded with the Nizám, under which the existing Haidarábad contingent force is maintained by the British Government, in lieu of the troops which the Nizám had been previously bound to furnish on demand in time of war; while for the payment of this contingent and other claims on the Nizám, districts then yielding a gross revenue of £500,000 per annum, including the present province of Berar, were assigned to our Government. By this treaty his highness was released from the obligation of furnishing a large force in time of war; the contingent ceased to be a part of the Nizám's army, and became an auxiliary force kept up by the British Government for the Nizám's use. The treaty was revised in 1860, and as a reward for services rendered by the Nizam in 1857, two of the districts formerly assigned to us were restored to him, and the territory of the Rájá of Surápur, which had been confiscated in consequence of the rebellion of the chief, was added to the Nizám's dominions.

BÉRARD, Frédéric, a French physician and writer on psychology, was born at Montpellier in 1789. He was educated at the famous medical school of that town, and afterwards proceeded to Paris, where he was for some time employed in connection with the *Dictionnaire des Sciences Médicales*. He returned to his native city in 1816, and published a work upon the principles of the school of Montpellier. In 1823 he was called to a chair of medicine at Paris, which he held for three years, being then nominated professor of hygiene at Montpellier. His health gave way under his labours, and he died, in 1828, at the early age of 39. A posthumous work, *Esprit des Doctrines Médicales de Montpellier*, was printed in 1830. Bérard's most important production is his treatise, *Des Rapports du Physique et du Moral*. According to him, consciousness or internal perception reveals to us the existence of an immaterial thinking, feeling, and willing subject, the self or soul. Alongside of this there is the vital force, the nutritive power, which uses the physical frame as its organ. The soul and the principle of life are in constant reciprocal action, and the first owes to the second, not the formation of its faculties, but the conditions under which they are evolved. (See Damiron, *Phil. en France au XIX^me Siècle*.)

BERBER, or El-Mecheref, a town of considerable size on the east bank of the Nile, some distance below the confluence of the Atbara, in about 18° N. lat. and 34° E. long. It is of importance as one of the main stations on the direct route from Khartoum to Cairo, and as the starting place of caravans for Suakin, on the eastern coast.

BERBERA, one of the most important seaports on the coast of the Somali country, in East Africa, 160 miles E.S.E. of Zeyla, and nearly opposite Aden, in 10° 26′ N. lat. and about 45° 4 E. long. It seems at one time to have been a town of some size, as there are still remains of an aqueduct extending inland for several miles; but its permanent inhabitants have for a long period been very few. From November to April, however, it becomes the general resort of from ten to twenty thousand persons from all the neighbouring countries. The Habr-auel-Somali, in whose district the town is situated, come down to the place in the beginning of October, with poles and mats and skins, and of these slight materials erect huts and warehouses, which are rented from them by the merchants, who begin to arrive as soon as the south-west monsoon changes into the north-east wind. The chief disadvantage of the locality is that water has to be brought a distance of several miles from the wells of Baraka. (See *J. R. G. Soc.*, 1849, p. 54, *et seq.*; Petermann's *Mittheil.* 1860, p. 427, and 1873, p. 40; *Bollet. d. Soc. Geogr. Ital.*, 1873.)

BERBICE, the eastern division of British Guiana. See Guiana.

BERCHEM, or Berghem, Nicholas, an eminent painter, born at Haarlem in 1624. He received instruction from his father, and from the painters Van Goyen, Wils, and Weeninx. His pictures, of which he produced an immense number, were in great demand, as were also his etchings and drawings. His landscapes are highly esteemed; and many of them have been finely engraved by John Visscher, an eminent artist in his own line. The distinguishing characteristics of Berchem's works are—breadth and just distribution of lights, grandeur of the masses of shadow, truth and simplicity of the figures, just gradation of distances, brilliancy and transparency of colouring, correctness of design, and elegance of composition. He died in 1683.

BERCHTESGADEN, or Berchtolsgaden, a small town, beautifully situated on the south-eastern confines of Bavaria, and long celebrated for its extensive mines of rock-salt, which were worked as early as 1174. Fresh water is brought into the mine, and, acting upon the salt rock, becomes brine. It is then run off in pipes to a reservoir in the vicinity; whence, by two hydraulic machines, it is raised 1500 feet, and conducted to Traunstein and Rosenheim, about forty miles farther inland. The town contains three old churches, and some good houses. Its inhabitants, amounting to 1760, are principally employed in the mines and in the manufacture of salt, while others are engaged in making those toys and other small articles of wood, horn, and ivory, for which the place has long been famous. The vicinity comprehends the most picturesque portion of Bavaria. The district of Berchtesgaden was formerly an independent spiritual principality, founded in 1109, and secularized in 1803. The abbey is now a royal castle, and in the neighbourhood a hunting-lodge was built by King Max II. in 1852.

BERDIANSK, a seaport town of Russia, in the government of Taurida, situated on the north-west shore of the Sea of Azoff, near the entrance of the River Berdianka into the Berdiansk Gulf, in 46° 45′ N. lat. and 36° 47′ E. long. Berdiansk was founded in 1827, at the suggestion of Vorontzoff, and by the following year was a regular settlement, which in 1835 was recognized as a town, and raised in 1842 to be capital of a circle. In 1838 its population was 3200, which had, in spite of the damage done to the town in 1855 by the English fleet, increased in 1860 to 9762. At that time it possessed two Greek churches and one Lutheran, and a Jewish and a Karaite synagogue. Its secular buildings comprised a custom-house, a hospital, a public library, and a theatre. The principal industries of the place are the making of bricks and tiles, the boiling of tallow, and the manufacture of macaroni. As a port it is of great importance. The roads are protected from every wind, except the south, which occasions a heavy surf; but this disadvantage has been lessened by the formation of a mole in 1863. Another inconvenience of the situation, however, is the rapid filling up of the port, which renders necessary

the removal of the wharves from time to time nearer to the sea. The chief articles of export are wheat, barley, linseed, rapeseed, rye, and oats; and the imports include hardwares, fruits, oil, and petroleum, the last-named being used for the lighting of the town. Large deposits of coal exist in the basin of the Azoff, and Berdiansk would afford the greatest facilities for its exportation. In the immediate neighbourhood are valuable salt-lagoons. Population in 1867, 12,223.

BERDICHEFF, a town of Russian-Poland, in the government of Kieff, 24 miles from Jitomir, on the Gniloppyat, and not far from the borders of Volhynia, to which it historically belongs. It consists of about a dozen main streets and a large number of cross lanes, by far the largest proportion of the houses being built of wood or brick. Besides the cathedral of the Assumption, finished in 1832, there are three or four other Greek churches, several synagogues, and places of worship for Roman Catholics and others, besides a Carmelite convent. The market, the exchange, the theatre, the Jewish almshouse, and the Elizabeth hospital, are among the most important secular buildings. A large number of schools are maintained. An extensive trade is carried on, both with the surrounding country and with Germany, in peltry, silk goods, iron and wooden wares, salt-fish, grain, cattle, and horses. Five great markets are held yearly, the most important being on 12th June and 15th August. Among numerous minor industries may be mentioned the manufacture of tobacco, soap, candles, oil, bricks, and leather. The population amounted in 1867 to 52,563, the Jews forming about 50,000 of the whole number.

Berdicheff is a place of some antiquity. In the treaty of demarcation between the Lithuanians and the Poles in 1546, it is assigned to the former. In the 16th century the Kievan waiwode, Yanut Teeshkevitch, built a castle in the village; and in 1627 he founded a monastery for Carmelite monks, to which he shortly afterwards presented the castle. The monks built themselves a crypt, and, as Berdicheff was subject to the incursions of Cossacks and Tatars, surrounded their monastery with rampart and ditch. In 1647, however, it was taken and plundered by Chmelnetzki, and the monks who had escaped did not return till 1663, and only obtained possession of their former property in 1717. In 1765 Stanislas Augustus, at the request of Prince Radzevil, allowed the city to hold ten yearly markets, and from that date its commercial prosperity began. In 1768 Casimir Pulavski, leader of the confederacy of Barr, fled, after the capture of that city, to Berdicheff, and there, with 700 men, maintained himself during a siege of 25 days. During the Polish domination, Berdicheff was in the Vratislau waiwodeship; after its annexation to Russia it was assigned to Jitomir and Volhynia; and in 1845 it was raised to be capital of a circle. In the beginning of the 18th century it had passed from the Teeshkevitch to the Zavpsh family, and from them was transferred by a marriage settlement to the Radzevils.

BERENGARIUS, a celebrated mediæval theologian, was born at Tours, 998 A.D. He was educated in the famous school of Fulbert of Chartres, and early acquired a great reputation for learning, ability, and piety. Appointed in 1031 superintendent of the cathedral school of his native city, he taught with such success as to attract pupils from all parts of France, and powerfully contributed to diffuse an interest in the study of logic and metaphysics, and to introduce that dialectic development of theology which is designated the scholastic. The earliest of his writings of which we have any record is an *Exhortatory Discourse* to the hermits of his district, written at their own request and for their spiritual edification. It shows a clear discernment of the dangers of the ascetic life, and a deep insight into the significance of the Augustinian doctrine of grace. About 1040 Berengar was made archdeacon of Angers. It was shortly after this that rumours began to spread of his holding heretical views regarding the sacrament of the supper. He had submitted the doctrine of transubstantiation (already generally received both by priests and people, although it had been first unequivocally taught and reduced to a regular theory by Paschasius Radbert only in 831) to an independent examination, and had come to the conclusion that it was contrary to reason, unwarranted by Scripture, and inconsistent with the teaching of men like Ambrose, Jerome, and Augustine. He did not conceal this conviction from his scholars and friends, and through them the report spread widely that he denied the common doctrine respecting the Eucharist. His early friend and school companion, Adelmann, archdeacon of Liége, wrote to him letters of expostulation on the subject of this report in 1046 and 1048; and a bishop, Hugo of Langres, wrote (about 1049) a refutation of the views which he had himself heard Berengar express in conversation. Berengar's belief was not shaken by their arguments and exhortations, and hearing that Lanfranc, the most celebrated theologian of that age, strongly approved the doctrine of Paschasius and condemned that of Ratramnus, he wrote to him a letter expressing his surprise, and urging him to reconsider the question. The letter arriving at Bec when Lanfranc was absent at Rome, was sent after him, but was opened before it reached him, and brought under the notice of Pope Leo IX. Because of it Berengar was condemned as a heretic, without being heard, by a synod at Rome and another at Vercelli, both held in 1050. His enemies in France cast him into prison; but the bishop of Angers and other powerful friends, of whom he had a considerable number, had sufficient influence to procure his release. At the Council of Tours (1054) he found a protector in the Papal legate, the famous Hildebrand, who, satisfied himself with the fact that Berengar did not deny the real presence of Christ in the sacramental elements, succeeded in persuading the assembly to be content with a general confession from him that the bread and wine, after consecration, were the body and blood of the Lord, without requiring him to define how. Trusting in Hildebrand's support, and in the justice of his own cause, he presented himself at the Synod of Rome in 1059, but found himself surrounded by fierce and superstitious zealots, who forced him by the fear of death to signify his acceptance of the doctrine "that the bread and wine, after consecration, are not merely a sacrament, but the true body and the true blood of Christ, and that this body is touched and broken by the hands of the priests, and ground by the teeth of the faithful, not merely in a sacramental but in a real manner." He had no sooner done so than he bitterly repented his weakness; and acting, as he himself says, on the principle that "to take an oath which never ought to have been taken is to estrange one's self from God, but to retract what one has wrongfully sworn to, is to return back to God," when he got safe again into France he attacked the transubstantiation theory more vehemently than ever. He continued for about sixteen years to disseminate his views by writing and teaching, without being directly interfered with by either his civil or ecclesiastical superiors, greatly to the scandal of the multitude and of the zealots, in whose eyes Berengar was "ille apostolus Satanæ," and the academy of Tours the "Babylon nostri temporis." An attempt was made at the Council of Poitiers in 1075 to allay the agitation caused by the controversy, but it failed, and Berengar narrowly escaped death in a tumult raised by fanatics. Hildebrand, now Gregory VII., next summoned him to Rome, and, in a synod held there in 1078, tried once more to obtain a declaration of his orthodoxy by means of a confession of faith drawn up in general terms; but even this strong-minded and strong-willed Pontiff, although sincerely anxious to befriend the persecuted theologian, and fully alive to the monstrous character of the dogma of transubstantiation as propounded by Pope Nicholas II. and

Cardinal Humbert at the synod held in 1059, was at length forced to yield to the demands of the multitude and its leaders; and in another synod at Rome (1079), finding that he was only endangering his own position and reputation, he turned unexpectedly upon Berengar and commanded him to confess that he had erred in not teaching a change *as to substantial reality* of the sacramental bread and wine into the body and blood of Christ. "Then," says Berengar, "confounded by the sudden madness of the Pope, and because God in punishment for my sins did not give me a steadfast heart, I threw myself on the ground, and confessed with impious voice that I had erred, fearing the Pope would instantly pronounce against me the sentence of condemnation, and, as a necessary consequence, that the populace would hurry me to the worst of deaths." He was kindly dismissed by the Pope not long after, with a letter recommending him to the protection of the bishops of Tours and Angers, and another pronouncing anathema on all who should do him any injury or call him a heretic. He returned home overwhelmed with shame and bowed down with sorrow for having a second time been guilty of a great impiety. He immediately recalled his forced confession, and besought all Christian men "to pray for him, so that his tears might secure the pity of the Almighty." He now saw, however, that the spirit of the age was against him, and hopelessly given over to the belief of what he had combated as a delusion. He withdrew, therefore, into solitude, and passed the rest of his life in retirement and prayer on the island of St Côme near Tours. He died there in 1088. In Tours his memory was held in great respect, and a yearly festival at his tomb long commemorated his saintly virtues.

Berengar left behind him a considerable number of followers. All those who in the Middle Ages denied the substantial presence of the body and blood of Christ in the Eucharist were commonly designated Berengarians. These so-called Berengarians differed, of course, in many respects from one another, even in regard to the nature of the supper. Berengar's own views on the subject may be thus summed up:—1. That bread and wine should become flesh and blood and yet not lose the properties of bread and wine was, he held, contradictory to reason, and therefore irreconcilable with the truthfulness of God. A change which would leave behind the properties or predicates of bread and wine, yet take away their substances, the subjects of these predicates, seemed to him inherently incredible. In working out the proof of this position he showed very considerable dialectical skill. At the same time he employed so many arguments, based on what is called nominalism, that his theory of the Eucharist has been described by M. de Remusat as "nominalism limited to a single question." 2. He admitted a change (*conversio*) of the bread and wine into the body of Christ, in the sense that to those who receive them they are transformed by grace into higher powers and influences—into the true, the intellectual, or spiritual body of Christ—so as to sustain and impart the life eternal. Christ does not descend from heaven to be portioned out by the hands of priests and received into the mouths of communicanes, but the hearts of true believers ascend to Christ in heaven, receive into themselves his true and imperishable body, and partake thereof in a spiritual manner. The unbelieving receive the external sign or *sacramentum;* but the believing receive in addition, truly although invisibly, the reality represented by the sign, the *res sacramenti*. Berengar draws his reasons for this view from Scripture. In confirmation of its correctness he adduces the testimonies of the earlier church teachers. 3. He rejected the notion that the sacrament of the altar was a constantly renewed sacrifice, and held it to be merely a commemoration of the one sacrifice of Christ. 4. He dwelt strongly on the importance of men looking away from the externals of the sacrament to the spirit of love and piety which they presuppose, and the divine power and grace, through the operation of which alone they can become channels of religious life. The transubstantiation doctrine seemed to him full of evil, from its tendency to lead men to overvalue what was sensuous and transitory in the sacrament, and to neglect what was spiritual and eternal. 5. He rejected with indignation the miraculous stories told to confirm the doctrine of transubstantiation. He saw in these legends unworthy inventions originated to awe and influence ignorant and superstitious minds. On this account he was falsely accused of denying miracles altogether. 6. Reason and Scripture seemed to him the only grounds on which a true doctrine of the Lord's supper could be rested. He had a confidence in reason very rare in the 11th century, but was no rationalist. He attached little importance to mere ecclesiastical tradition or authority, and none to the voice of majorities, even when sanctioned by the decree of a Pope. In this, as in other respects, he was a precursor of Protestantism.

The opinions of Berengar are to be ascertained from the works written in refutation of them by Adelmann, Lanfranc, Guilmund, &c.; from the fragments of the *De sacr. cœna adv. Lanfr. liber*, edited by Staudlin (1820-29); and from the *Liber posterior*, edited by A. F. and F. T. Vischer (1834). See also the *Berengarius Turonensis* of Lessing (1770), and especially of Sudendorf (1850); the *Church Histories* of Gieseler, ii. 396-411 (Eng. transl.), and Neander, vi. 221-260 (Engl. transl.); Prantl's *Geschichte der Logik*, ii. 70-75, and Hauréau's *Histoire de la Philosophie Scolastique*, i. 225-238. (R. F.)

BERENICE, an ancient city on the western shore of the Red Sea, in 23° 56′ N. lat. and 35° 34′ E. long., near the head of the *Sinus Immundus* or Foul Bay. It was founded or enlarged by Ptolemy II., and grew into great importance as an entrepôt for the trade between Asia and Africa. Its harbour was sheltered on the north-east by an island that had topaz deposits, and in the neighbourhood were emerald mines. The ruins of a temple in the Egyptian style, but with Greek ornaments, are among the most important discovered on the site.

BERENICE, the name of several Egyptian and Jewish princesses. The two most generally known are—

1. Berenice, the daughter of Magus, king of Cyrene, and the wife of Ptolemy Euergetes, of Egypt. During her husband's absence on an expedition to Syria, she dedicated her hair to Venus for his safe return, and placed it in the temple of the goddess at Zephyrium. The hair having by some unknown means disappeared, Conon, the mathematician, explained the phenomenon in courtly phrase, saying that it had been carried to the heavens and placed among the stars. The name *Coma Berenices*, applied to a constellation, commemorates this incident. Only a few lines remain of the poem in which Callimachus celebrated the transformation, but there is a fine translation of it by Catullus.

2. Berenice, daughter of Agrippa I., king of Judæa, and born probably about 28 A.D. She was first married to her uncle, Herod, after whose death she lived for some years with her brother Agrippa, not without scandal. Her second husband was Polemo, king of Cilicia, but she soon deserted him, and returned again to Agrippa, with whom she was living when Paul appeared before him at Cæsarea. During the devastation of Judæa by the Romans, she fascinated Titus, whom she accompanied to Rome, and who would willingly have married her had it not been for the hatred cherished by the people against the Jewish race.

BEREZINA, a river of Russia, in the government of Minsk, forming a tributary of the Dnieper. It rises in the marshes of Boresoff, and has a course of more than 330 miles, for the most part through low-lying but well-

wooded country. Its width increases from 40 or 60 feet near Bobruisk to 100 feet at the mouth of the Svesloch, one of its western tributaries. As a navigable river, and forming a portion of the great canal system which unites the Black Sea with the Baltic, it is of great importance for the commerce of the country, but unfortunately it is subject to severe floods. The principal ports along its course are Boresoff, Berezino, Yakshetzec, Bobruisk, and Parichi. In history the river has been rendered famous by the crossing of the army of Napoleon in 1812. See Stuckenberg's *Hydrographie*, iii., and *Canäle;* Guldenstadt's *Reise*.

BEREZOFF, a town of Asiatic Russia, capital of a circle in Tobolsk, 700 miles N. of that city, situated on three hills on the left bank of the Sosna, 13 miles above its mouth, and on the Bogul, a tributary of the Sosna, in 63° 55′ N. lat. and 64° 7′ E. long., at a height of 297 feet above the sea-level. Berezoff was founded in 1593 for the collection of taxes near the Ostyak settlement of Sûmgût-Bozh, which means in Russian *Berezovi-Gorod*, or Birch-town. Berezoff was more than once exposed to destructive conflagrations, as, for example, in 1719 In the second quarter of the 18th century Berezoff was appointed a place of banishment for certain important royal families. In 1727 Prince Menschikoff was sent thither with his sons and two daughters, of whom the eldest, Mary, was the first bride of Peter II.; and in 1730 he was followed by Prince Ivan Dolgoruki, with his wife, father, mother, three brothers and three sisters, of whom Catherine was the second bride of Peter II. In 1742 General Osterman was sent to Berezoff with his wife, and died there in 1747. In 1782 the town was raised to the rank of chief town of a district of the Tobolsk government. In 1808 it was again burned down. In 1860 it had two stone churches, a cathedral called the Resurrection of the Lord, near which lie buried Mary Menschikoff and some of the Dolgorukis, and the church of Our Lady's Conception, built on the site of the Menschikoff building. There are in the town a departmental school, a lazaretto, and a strangers' hospital. The trade, which is of considerable importance, consists of furs, mammoth bones, dried and salted fish, &c. There is a yearly market, in which the transactions amount to £9000. Population in 1860, 1462.

BERG (*Ducatus Montensis*), a former duchy of Germany, on the right bank of the Rhine, bounded on the N. by the duchy of Cleves, E. by the countship of Mark and duchy of Westphalia, and on the S. and W. by the bishopric of Cologne. Its area was about 1188 square miles. The district was raised in 1108 to the rank of a countship, but did not become a duchy till the 14th century, after it had passed into the possession of the Julich family. On the extinction of this house in 1609, Austria laid claim to the duchy as an imperial fief; but, in keeping with the wishes of the inhabitants, it was administered conjointly by the electors of Saxony and Brandenburg and the Elector Palatine till 1624, when by the Düsseldorf treaty the last of the three obtained the sole authority. In 1806 it was bestowed by Napoleon, along with the duchy of Cleves and other possessions, on Murat, who bore the title of grand duke of Berg; and after Murat's elevation to the throne of Naples, it was transferred to Louis, the son of the king of Holland. By the Congress of Vienna in 1815 it was made over to Prussia, and now forms a flourishing part of her territory.

BERGAMA, a town of Asia Minor, with 2500 inhabitants. See PERGAMUS.

BERGAMO, a northern province of Italy, bounded on the N. by Sondrio, E. by Tyrol and Brescia, S. by Cremona, and W. by Milan and Como. The northern portion is mountainous and well wooded, while the southern belongs to the alluvial plain of Lombardy. To the N. and W. of Lake Iseo there are numerous mineral wells, the most important of which are those of Trescoro. Marble is abundant in the mountains, and there are valuable iron mines. At an early period the wealth of the capital appears to have been increased by the working of copper mines in the district. (See Finazzi, *Sulle antiche miniere di Bergamo*, Milan, 1860.) The vine and flax are largely grown, and the culture of the silk-worm is extensively carried on. The people speak a rough dialect, and are liable to be laughed at by the other Italians. The two stock characters of popular Italian comedy, Harlequin or Truffaldino and the sly Brighella, were both at one time represented as natives of the Bergamo district.

BERGAMO, the capital of the above province, is situated between the Brembo and Serio, two tributaries of the Adda, 39 miles N.E. of Milan, on the railway that runs from Venice to the Lake of Como. It consists of a new and an old town, the latter known as the *Città*, or city, being built on a hill, while the former, or *Borgo S. Leonardo*, occupies the level ground below. On the eastern side there are also two important suburbs, *S. Caterina* and *Palazzo*. Bergamo is the seat of a bishop and a prefect, and possesses a school of art known as the Accademia Carrara, a museum, a lyceum, a library contained in the Palazzo Vecchio or Broletto, a musical institute, two theatres, and various scientific societies. There are also a lunatic asylum, a hospital, and other charitable institutions. Among its numerous churches may be mentioned S. Maria Maggiore, which dates from 1173, and the neighbouring Colleoni chapel, the old Arian church of San Alessandro della Croce, S. Bartolommeo, and S. Grata. The principal objects of industry in the city are silk, cotton, and woollen goods, iron-wares, waxcloth and wax candles, and playing cards. A large fair, called the Fiera di S. Alessandro, is annually held in the new town. It dates from the 10th century, and is of great importance, especially for the silk trade. Bergamo, or *Bergomum*, was a municipal town during the Roman empire, and, after being destroyed by Attila, became one of the most flourishing cities of the Lombard kings, who made it the capital of a duchy. In the 15th century it was appropriated and fortified by the Venetians. In 1509 it was occupied by Louis XII. of France, who retained it for seven years, and then restored it to Venice. In 1796 the French again made themselves masters of the city, and constituted it the capital of their department of Serio. Bergamo was the birthplace of Tiraboschi, Rubini, and Donizetti. Population, 37,363.

BERGAMOT, OIL OF, an essential oil obtained from the rind of the fruit of a species of *Citrus*, regarded by Risso as *C. bergamia*, but not generally believed to constitute a distinct species. The bergamot is a small tree with leaves and flowers like the bitter orange, and a round fruit nearly 3 inches in diameter, with a thin lemon-yellow smooth rind. The tree is cultivated in the neighbourhood of Reggio, in Calabria, whence the entire supply of bergamot oil is drawn. The oil is contained in small vesicles in the rind, from which it can be expressed by simple pressure in the hand. An old method of obtaining the oil, now almost superseded, is by skinning the fruit, and pressing the outside of the rind against a sponge. The rind being turned over so that the outside becomes concave, the vesicles are easily ruptured by hand pressure against the sponge, which absorbs the oil as it escapes. The oil is now obtained by placing several fruits in a saucer-shaped apparatus, the surface of which is cut into radiating sharp-edged grooves. Against the sharp edges of this dish the fruits are rapidly revolved by means of a heavy cover placed above it, which is moved by a cog wheel. The oil vessels are ruptured by pressure against the knife edges, and the oil which exudes falls through small perforations in the bottom into a vessel

placed underneath. It is allowed to rest till a greasy substance—bergamot camphor—deposits, after which it is bottled for use. Bergamot oil is a limpid greenish-yellow fluid of a specific gravity of 0·869, of a powerful but pleasant citrine odour and an aromatic bitterish taste. It consists of a mixture of two essential oils, the most volatile of which is a pure hydrocarbon isomeric with oil of turpentine; the other, containing oxygen, being regarded as a hydrate of lemon oil. The chief use of bergamot oil is in perfumery, and as a flavouring material in cookery.

BERGEN, a city and seaport on the west coast of Norway, capital of the province of South Bergen, in 5° 29′ E. long. and 60° 23′ N. lat. It is situated on a rocky promontory at the head of a deep bay called the Vaag, has a fine harbour with two good entrances, and is surrounded by hills, some of which attain the height of 2000 feet. Towards the sea it is defended by the ancient fortress of Bergenhuus, the citadels of Frederiksberg and Sverresberg, and some lesser works The appearance of the town, which rises in the form of an amphitheatre and is generally well built, is decidedly picturesque, with its wooden houses painted of various colours. It contains a cathedral, several churches, of which the oldest, St Mary's, dates from the 12th century, hospitals, a lazaretto, a national museum, a diocesan college, a naval academy, a school of design, public libraries, various charitable institutions, and a theatre. It is the seat of a bishopric, and possesses a tribunal of secondary jurisdiction and one of the three public treasuries of Norway. Bergen has a considerable export trade, which consists of stockfish, lobsters, fish-roes, herrings, whale oil, horns, skins, rock moss, and timber, and is chiefly carried on with the northern countries of Europe. In 1867 the number of steamships that entered the port was 164, with a tonnage of 28,454. The imports of that year amounted to £92,600, and the exports to £344,000. Bergen was founded in the 11th century by Olaf the Peaceful, king of Norway. In 1445 the Hanseatic League established a factory in the city, and continued to have almost the sole control of the trade till 1558, when it was expelled by the Norwegians, who found its presence oppressive. There is still a kind of German colony in the place, which keeps up the Hanseatic tradition, and the old German church, hospital, and "factory" or *contor* are still extant, the latter furnishing excellent warehouse accommodation. A large part of the town was burnt down in 1855, and has since been rebuilt in a more regular and open manner. It is the second largest town in Norway Population (1870), 30,252.

BERGEN-OP-ZOOM, a town of Holland, in the province of North Brabant, situated on both sides of the River Zoom, near its confluence with the East Scheldt, in 51° 29′ N. lat., and 4° 17′ E. long. It is about 15 miles N. of Antwerp, and 22 W.S.W. of Breda. The houses are well built, the market-places and squares handsome and spacious. It possesses a port and an arsenal, and contains a town-house, a Latin school, and an academy of design and architecture. The tower of the old castle is remarkable for an increase of its breadth from the bottom upwards, and for its liability to be rocked when struck by a strong wind. There are numerous tile-works and potteries of fine ware; and a considerable trade is carried on in anchovies caught in the Scheldt.

In the 13th century Bergen-op-Zoom became the seat of Count Gerhard of Wesemael, who surrounded it with walls In 1533 it was erected by Charles V. of Germany into a marquisate, which was successively held by the families of Berghes, Merode, Witthem, s'Heerenbergh, Hohenzollern, Tour d'Auvergne, and Sulzbach, and thus passed to the house of Bavaria, which, however, in 1801 abdicated its rights in favour of the Dutch republic. In 1576 the town joined the United Netherlands, and was shortly afterwards fortified. In 1588 it was unsuccessfully besieged by the duke of Parma (see Motley's *United Netherlands*, chap. xx.), and in 1605 it was suddenly attacked by Du Terail (*Ibid.* chap. xliv.) In 1622 it defied the utmost attempts of Spinola, who was forced to abandon the enterprise after a siege of ten weeks and the loss of 1200 men. Its fortifications were greatly strengthened in 1688 by Coehorn, who, it was believed, had almost rendered it impregnable: and in 1725 they were further extended, In 1747, however, the town was taken by the French general Lowendal. Restored at the end of the war, it was again in 1795 taken by Pichegru. The English, under Sir Thomas Graham, afterwards Lord Lynedoch, in March 1814 made an attempt to take it by a *coup de main*, but were driven back with great loss by the French, who, however, surrendered the place by the treaty of peace in the following May.

BERGERAC, the chief town of an arrondissement in the department of Dordogne, in France, situated in a fertile plain, 30 miles S.S.W. of Périgueux, on both banks of the Dordogne, which is here crossed by a fine bridge of five arches and rendered navigable by a large dam. The town is rather poorly built, and, in spite of its age, contains no monuments of antiquarian interest. It is, however, a place of great industrial activity, has a communal college, tribunals of primary jurisdiction and commerce, and a public library; and manufactures paper, iron and copper wares, hats, hosiery, and leather. The wines of the neighbourhood are in good repute, and form an important article in the trade of the town, which is principally carried on with Bordeaux and Libourne. Bergerac owes its origin to the abbey of St Martin, which was founded in 1080, and during the English invasions it played an important part as a fortress. In the 16th century it was a very flourishing and populous place, but most of its inhabitants having embraced Calvinism it suffered greatly during the religious wars. Its fortifications and citadel were demolished by Louis XIII. in 1621, and it was injuriously affected by the revocation of the Edict of Nantes. Population in 1872, 8679.

BERGMANN, Torbern Olof, Swedish chemist and naturalist, was born at Catherinberg, West Gothland, in 1735. At the age of seventeen he entered the University of Upsala, and distinguished himself by extraordinary assiduity in study, directing his attention more particularly to the natural sciences. During a residence at home rendered necessary by his weak health, he employed himself in collecting specimens of insects and plants, which he forwarded to Linnæus, who was much pleased with them. In 1756 he gained great reputation by his memoir on the *Coccus aquaticus*, which, contrary to the opinion of Linnæus, he proved to be nothing but the ovum of a certain species of leech. Some years later he was made professor of physics at Upsala, and published numerous scientific memoirs. In 1767 the chair of chemistry and mineralogy having become vacant through the resignation of Wallerius, Bergmann resolved to become a candidate. He had not hitherto devoted special attention to chemistry, but in a very short period by incredible application he produced as evidence of his fitness for the post a paper on the composition of alum, which is still regarded as a masterpiece. He was appointed to the chair, which he held till his death in 1784. In 1776 he had declined an offer from the king of Prussia inviting him to settle in Berlin. Bergmann was an unusually acute and sagacious analytical chemist, and made extensive and constant use of the laboratory He described very carefully the properties of carbonic acid gas, and gave a valuable analysis of mineral waters. His researches in mineralogy, to which he applied his geometrical knowledge, were even more important, and led the way to Hauy's discovery and classification. The theory of elective or chemical affinities, which he worked out very fully, has had great influence in the history of chemistry. A collection of Bergmann's papers was published from 1779 to 1781, *Opuscula Physica et Chemica*, 6 vols. They have been translated into French, German, and English.

BERKELEY, a market-town in the county of Gloucester, near the River Severn, on the Midland Railway. It is pleasantly situated on a gentle eminence, in a rich pastoral vale to which it gives name, and which is celebrated for its dairies, producing the famous cheese known as "double Gloucester." The town has a handsome church, a grammar school, a town-hall, a market-house, and some trade in coal, timber, malt, and cheese. Berkeley was the birthplace of the celebrated Dr Jenner, whose remains are interred in the church. Berkeley castle, on an eminence S.E. of the town, was built in the reign of Henry I. out of the ruins of a nunnery which had been in existence some time before the Conquest. It suffered considerably during the civil wars of the 17th century, but is still one of the noblest baronial castles existing in England. It is noted as the scene of the barbarous murder of Edward II. Since the time of Henry II. it has been in the hands of the Berkeley family. Population of the parish in 1871, 4607,—about a fourth of the number being in the town.

BERKELEY, George, bishop of Cloyne, one of the most subtle and original English metaphysicians, was born on the 12th March 1685, at Dysert castle, on the banks of the Nore, about two miles below Thomastown, Ireland. Not much is known of his family, who seem to have been connected with the noble English house of the same name. His father, William Berkeley, was an officer of customs, and appears to have had at one time the rank of captain in the army. We know next to nothing of the mental character of either him or his wife. George, their eldest son, was entered in 1696 at the famous Kilkenny school, of which he was not the only pupil afterwards distinguished. He was remarkably well advanced in studies for his years, and in 1700 was qualified to matriculate at Trinity College, Dublin. There, for the first time, we begin to have a fair knowledge of the circumstances in which he was placed, and of the peculiar mental qualities with which he was endowed. From his own account, and from the few notices of contemporaries, we can gather that his was a mind of peculiar subtilty, keen to probe to the very foundation any fact presented to it, and resolutely determined to rest satisfied with no doctrine which had only the evidence of authority or custom, and was not capable of being realized in consciousness. This turn of mind naturally led him somewhat off the beaten track of university studies; he was not understood by his college companions, and began to be looked upon as either the greatest dunce or the greatest genius in the university. To such a reputation his eccentricity of manner, which seems to have resulted from his occasional absorption or passionate enthusiasm, largely contributed. Of the greatest importance for the development of his rare powers in a definite direction was the general condition of thought at the time of his residence at Dublin. The older text-books of physics and philosophy were no doubt in use (Dublin in this respect has always been conservative), but alongside of them the influences of the new modes of thinking were streaming in. The opposed physical systems of Descartes and Newton had begun to be known; the new and powerful calculus was being handled; the revolution in metaphysical speculation inaugurated by Descartes had reached Dublin; and, above all, the first great English work on pure philosophy, the *Essay* of Locke, had been translated into Latin, and its doctrines were being eagerly and minutely discussed by the young Trinity College students. Add to this the undoubted influence exercised by the presence in Dublin of such men as the university provost, Peter Browne, afterwards bishop of Cork, and King, archbishop of Dublin from 1703, and it will readily be seen that Berkeley, to use Professor Fraser's words, "entered an atmosphere which was beginning to be charged with the elements of reaction against traditional scholasticism in physics and in metaphysics."

Although more competent than any man of his time to appreciate these new movements of thought, Berkeley did not neglect the routine work of the university. He had a distinguished career, was made scholar in 1702, took his B.A. degree in 1704, and obtained a fellowship in 1707. That his interest, however, was mainly directed towards subjects purely philosophical, is evidenced partly by the share he took in setting afloat a speculative society in which the problems suggested by Descartes and Locke seem to have been discussed with infinite vigour, but, above all, by his *Common Place Book*, containing his thoughts on physics and philosophy from about the year 1703. This curious document, one of the most valuable autobiographical records in existence, throws a flood of light on the growth of Berkeley's own conceptions, and enables us to understand, far more clearly than we otherwise could, the significance of his first published works. In the *Common Place Book*, if in any writing, is to be found the keen consciousness of possessing a fresh, creative thought, the application of which will change the whole aspect of speculative science. The very first sentences refer to some new principle, and the whole book thereafter is occupied turning over and over again the new conception, showing the different aspects it assumes, and the various applications it has, bringing it face to face with possible objections, and critically considering the relation in which it stands to the fundamental thoughts of his great predecessors, Descartes, Malebranche, and Locke. So far as reading goes, the *Common Place Book* shows but a slight acquaintance with ancient or scholastic philosophies; it is evident that the author does not appreciate Spinoza; he does not refer to Leibnitz; Malebranche is frequently mentioned, but hardly in such a way as to manifest sympathetic understanding of him; Norris, the English follower of Malebranche, seems to be unnoticed; More and the Mystics, when referred to, are quoted on isolated points, and to their system the young philosopher evidently felt no attraction. Descartes and Locke, above all the latter, are his real masters in speculation, and it is from the careful consideration of their systems that the new principle has sprung to light. And what is this principle? As Professor Fraser has said, there are many ways of expressing it, and Berkeley himself has never given any very definite enunciation. To put it in a form as nearly as possible resembling the statements in the *Common Place Book*, it may be expressed in the proposition that no existence is conceivable and therefore possible which is not either conscious spirit or the ideas (*i.e.* objects) of which such spirit is conscious. Existing things consist of ideas or objects perceived or willed, while perception and volition are inconceivable and impossible save as the operations of mind or spirit. In the language of a later philosophy, the principle is that of the absolute synthesis of subject and object; no object exists apart from mind. Mind is therefore the deepest reality; it is the *prius* both in thought and in existence, if for the moment we assume the popular distinction between these two. From this primitive truth, which, it seems to Berkeley, merely requires careful consideration in order to be at once accepted, he never wavers. Let attention be but confined to the only possible *meaning* which existence can have, and, Berkeley thinks, the principle must appear self-evident. Thus he puts in a new light the perennial problems of philosophy, and instead of discussing the nature and relations of assumed entities, such as matter, substance, or cause, would ask us to consider whether or not these have any significance apart from the perceptions or volitions of conscious spirit, what in that case they do mean, and whether the supposed difficulties connected with them do

not vanish when their true interpretation is thoroughly grasped. Of all these difficulties that concerned with the nature of matter is of greatest importance to Berkeley. From misconceptions of the true nature of material substance have flowed, according to him, the materialism, scepticism, and infidelity which disfigured the age; and all these are completely banished by the new principle. The applications of his principle and his own inclinations led Berkeley into other departments of science which he was not so well qualified to handle. The first result of the principle, as he conceived it, is undoubtedly empiricism in the theory of cognition. The ultimate elements of knowledge are the minima of consciousness, presentative or representative; pure thought and abstract ideas are not capable of being realized by the mind, and are therefore impossible. The only mathematical processes to which these minima can be subjected are addition and subtraction; and consequently great part of the *Common Place Book* is occupied with a vigorous and in many points exceedingly ignorant polemic against the fundamental conceptions of the fluxional and infinitesimal calculus, a polemic which Berkeley carried on to the end of his days.

He soon began to appear as an author. In 1707 he published two short tracts on mathematics, and in 1709 the *New Theory of Vision*, in which he applied his new principle, though without stating it explicitly. The new theory is a critical examination of the true meaning of the externality which is apparently given in visual consciousness, and which, to the unphilosophical mind, is the strongest evidence of the independent existence of outer objects. Such visual consciousness is shown to be ultimately a system of arbitrary signs, symbolizing for us certain actual or possible tactual experience—in fact, a language which we learn through custom. The difference between the contents of the visual and the tactual consciousness is absolute; they have no element in common. The visible and visual signs are definitely connected with tactual experiences, and the association between them, which has grown up in our minds through custom or habit, rests upon, or is guaranteed by, the constant conjunction of the two by the will of the Universal Mind. But this synthesis, whether on the objective side as the universal thought or course of nature, or on the subjective side as mental association, is not brought forward prominently by Berkeley. It was at the same time perfectly evident that a quite similar analysis might have been applied to tactual consciousness, which does not give externality in its deepest significance any more than visual; but it was with deliberate purpose that Berkeley at first drew out only one side of his argument. In 1710 the new doctrine received its full statement in the *Principles of Human Knowledge*, where externality in its ultimate sense as independence of all mind is considered; where matter, as an abstract, unperceived substance or cause, is shown to be an impossible and unreal conception; where true substance is affirmed to be conscious spirit, true causality the free activity of such a spirit, while physical substantiality and causality in their new meaning are held to be merely arbitrary but constant relations among phenomena connected subjectively by suggestion or association, conjoined objectively in the Universal Mind. In ultimate analysis, then, nature is conscious experience, and forms the sign or symbol of a divine, universal intelligence and will.

In the preceding year Berkeley had been ordained as deacon, and in 1711 he delivered his *Discourse on Passive Obedience*, in which he deduces moral rules from the intention of God to promote the general happiness, thus working out a theological utilitarianism, which may with advantage be compared with the later expositions of Austin and Mill. From the year 1707 he had been engaged as college tutor; in 1712 he paid a short visit to England, and in April of the following year he was presented by Swift at court. His splendid abilities and fine courteous manners, combined with the purity and uprightness of his character, made him a universal favourite. While in London he published his *Dialogues* (1713), a more popular exposition of his new theory; for exquisite facility of style these are perhaps the finest philosophical writings in the English language. In November of the same year he became chaplain to Lord Peterborough, whom he accompanied on the Continent, returning in August 1714. He travelled again in 1715 as tutor to the son of Dr Ashe, and was absent from England for five years. On his way home he wrote and sent to the French Academy the essay *De Motu*, in which is given a full account of his new conception of causality, the fundamental and all-comprehensive thought in his philosophy. In 1721, during the disturbed state of social relations consequent on the bursting of the great South Sea bubble, he published an *Essay towards preventing the Ruin of Great Britain*, which shows the intense interest he took in all practical affairs. In the same year he returned to Ireland as chaplain to the duke of Grafton, and was made divinity lecturer and university preacher. In 1722 he was appointed to the deanery of Dromore, a post which seems to have entailed no duties, as we find him holding the offices of Hebrew lecturer and senior proctor at the university. The following year brought him an unexpected addition of fortune, Miss Vanhomrigh, Swift's Vanessa, having left him half her property. It would appear that he had only met her once at dinner. In 1724 he was nominated to the rich deanery of Derry, but had hardly been appointed before he was using every effort to resign it in order to devote himself to his enthusiastically conceived scheme of founding a college in the Bermudas, and extending its benefits to the Americans. With infinite exertion he succeeded in obtaining from Government a promise of £20,000, and, after four years spent in preparation, sailed in September 1728, accompanied by some friends and by his wife, daughter of Judge Forster, whom he had married in the preceding month. Their destination was Rhode Island, where they resolved to wait for the promised grant from Government. Three years of quiet retirement and study were spent in the island. Berkeley bought a farm, made many friends, and endeared himself to the inhabitants. But it gradually became apparent that Government would never hand over the promised grant, if indeed they had ever seriously contemplated doing so. Berkeley was therefore compelled reluctantly to give up his cherished plan. Soon after his return he published the fruits of his quiet studies in *Alciphron, or the Minute Philosopher* (1733), a finely written work in the form of dialogue, critically examining the various forms of freethinking in the age, and bringing forward in antithesis to them his own theory, which shows all nature to be the language of God. The work was extremely popular. In 1734 he was raised to the bishopric of Cloyne, and at once went into residence. The same year, in his *Analyst*, he attacked the higher mathematics as leading to freethinking; this involved him in a hot controversy. The *Querist*, a practical work in the form of questions on what would now be called social or economical philosophy, appeared in three parts, 1735, 1736, 1737. In 1744 was published the *Siris*, partly occasioned by the controversy with regard to tar-water, but rising far above the petty circumstance from which it took its rise, and in its chain of reflections revealing the matured thoughts and wide reading of its author, while opening up hidden depths in the Berkeleian metaphysics. In 1751 his eldest son died, and in 1752 he removed with his family to Oxford for the sake of his son George, who was studying there. On the even-

ing of the 14th January 1753, he expired suddenly and painlessly in the midst of his family. And thus quietly closed one of the purest and most beautiful lives on record. His remains were deposited in Christ Church, Oxford.

Although Berkeley's new principle is susceptible of brief statement, it is by no means equally possible to give in short compass an adequate account of its systematic application to the several problems of philosophy. It may be sufficient here to indicate generally the relation of the new conception to preceding systems, and to inquire how far the principle is metaphysically justifiable. In the philosophies of Descartes and Locke a large share of attention had been directed to the idea of matter, which was held to be the abstract, unperceived background of real experience, and was supposed to give rise to our ideas of external things through its action on the sentient mind. Knowledge being limited to the ideas produced could never extend to the unperceived matter, or substance, or cause which produced them, and it became a problem for speculative science to determine the grounds for the very belief in its existence. Philosophy seemed about to end in scepticism or in materialism. Now Berkeley put this whole problem in a new light by pointing out that a preliminary question must be raised and answered. Before we deduce results from such abstract ideas as cause, substance, matter, we must ask what in reality do these mean,—what is the actual content of consciousness which corresponds to these words? Do not all these ideas, when held to represent something which exists absolutely apart from all knowledge of it, involve a contradiction? Are they not truly, when so regarded, inconceivable, and mere arbitrary figments which cannot possibly be realized in consciousness? In putting this question, not less than in answering it, consists Berkeley's distinct originality as a philosopher. The essence of the answer, as has been already seen, is that the universe is inconceivable apart from mind,—that existence, as such, denotes conscious spirits and the objects of consciousness. Matter and external things, in so far as they are thought to have an existence beyond the circle of consciousness, are impossible, inconceivable, absurd. External things are things known to us in immediate perception. To this conclusion Berkeley seems, in the first place, to have been led by the train of reflection that naturally conducts to subjective or egoistic idealism. It is impossible to overstep the limits of self-consciousness; whatever words I use, whatever notions I have, must refer to and find their meaning in facts of consciousness. And there can be no doubt that in certain earlier aspects of his theory, where, for example, it appears as a mere analysis of what is meant by *reality*, it does not rise above this subjective stand-point. But this is by no means the whole or even the principal part of Berkeley's philosophy; it is essentially a theory of causality, and this is brought out gradually under the pressure of difficulties in the first solution of the early problem. To merely subjective idealism, sense percepts differ from ideas of imagination in degree, not in kind; both belong to the individual mind. To Berkeley, however, the difference is fundamental; sense ideas are not due to our own activity, they do not result from our will; they must therefore be produced by some other will,—by the divine intelligence. Sense experience is thus the constant action upon our minds of supreme active intellect, and is not the consequence of dead inert matter. It might appear, therefore, that sensible things had an objective existence in the mind of God; that an idea so soon as it passes out of our consciousness passes into that of God. This is an interpretation, frequently and not without some justice, put upon Berkeley's own expression. But it is not a satisfactory account of his theory. Berkeley is compelled to see that an immediate perception is not a *thing*, and that what we consider permanent or substantial is not a sensation but a group of qualities, which in ultimate analysis means sensations either immediately felt or such as our experience has taught us would be felt in conjunction with these. Our belief in the reality of a thing may therefore be said to mean assurance that this association in our minds between actual and possible sensations is somehow guaranteed. Further, Berkeley's own theory would never permit him to speak of possible sensations, meaning by that the ideas of sensations called up to our minds by present experience. He could never have held that these afforded any explanation of the permanent existence of real objects. His theory is quite distinct from this, which really amounts to nothing more than subjective idealism. External things are produced by the will of the divine intelligence; they are caused, and caused in a regular order; there exist in the divine mind archetypes, of which sense experience may be said to be the realization in our finite minds. Our belief in the permanence of something which corresponds to the association in our minds of actual and possible sensations means belief in the orderliness of nature; and *that* is merely assurance that the universe is pervaded and regulated by mind. Human science is occupied in endeavouring to decipher the divine ideas which find realization in our limited experience, in trying to interpret the divine language of which natural things are the words and letters, and in striving to bring human conceptions into harmony with the divine thoughts. Instead, therefore, of fate or necessity, or matter, or the unknown, a living, active mind is looked upon as the centre and spring of the universe, and this is the essence of the Berkeleian metaphysics.

It may be safely said that the deeper aspects of Berkeley's new thought have been almost universally neglected or misunderstood. Of his spiritual empiricism only one side has been accepted by later thinkers, and has been looked upon as the whole. The subjective mechanism of association which with Berkeley is but part of the true explanation, and is dependent on the objective realization in the divine mind, has been received as in itself a satisfactory theory. *Sunt Cogitationes* has been regarded by thinkers who profess themselves Berkeleians as the one proposition warranted by consciousness; the empiricism of his philosophy has been eagerly welcomed, while the spiritual intuition, without which the whole is to Berkeley meaningless, has been cast aside. For this he is himself in no small measure to blame. The deeper spiritual intuition, present from the first, was only brought into clear relief in order to meet difficulties in the earlier statements; and the extension of the intuition itself beyond the limits of our own consciousness, which completely removes his position from mere subjectivism, rests on foundations uncritically assumed, and at first sight irreconcilable with certain positions of his system. The necessity and universality of the judgments of causality and substantiality are taken for granted; and there is no investigation of the place held by these notions in the mental constitution. The relation between the divine mind and finite intelligence, at first thought as that of agent and recipient, is complicated and obscure when the necessity for explaining the permanence of real things comes forward. The divine archetypes, according to which sensible experience is regulated and in which it finds its real objectivity, are different in kind from mere sense ideas, and the question then arises whether in these we have not again the "things as they are," which Berkeley at first so contemptuously dismissed. He leaves it undetermined whether or not our knowledge of sense things, which is never entirely presentative, involves some reference to this objective course of nature or thought of the divine mind. And if so, what is the nature of the notions necessarily implied in the simplest knowledge of a *thing*, as distinct from mere sense feeling? That in knowing objects certain thoughts are implied which are not presentations or their copies, is at times dimly seen by Berkeley himself; but he was content to propound a question with regard to those notions, and to look upon them as merely Locke's ideas of relation. Such ideas of relation are in truth the stumbling-block in Locke's philosophy, and Berkeley's empiricism is equally far from accounting for them.

With all these defects, however, Berkeley's new conception marks a distinct stage of progress in human thought. His true place in the history of speculation may be seen from the simple observation that the difficulties or obscurities in his scheme are really the points on which later philosophy has turned. He once for all lifted the problem of metaphysics to a higher level, and, in conjunction with his great successor, Hume, determined the form into which later metaphysical questions have been thrown.

The classical edition of Berkeley's works is that by Professor Fraser (4 vols.—vols. i.-iii., *Works*; vol. iv., *Life, Letters, and Dissertation on his Philosophy*, Clarendon Press, 1871), who has been the first, there and in various essays, to exhibit the true form of Berkeley's philosophy. See also Ueberweg's notes to his translation of the *Principles* (1869); Krauth's American edition of the *Principles*, with Prof. Fraser's introduction and notes, and a translation of those of Ueberweg; Collyns Simon, *Universal Immaterialism* (1847); *Nature and Elements of the External World* (1862); Friedrich, *Ueber Berkeley's Idealismus* (1870). Discussions on various points of Berkeley's doctrine will be found in Fichte's *Zeitschrift*, vol. lvi. *sqq.*; Mill's *Dissertations*, vols. ii. and iv.; Huxley, *Critiques and Addresses*, p. 320, *sqq.*; Ferrier, *Remains*, vol. ii. Two adverse views of the *Theory of Vision* may also be noted—Bailey, *Review of Berkeley's Theory of Vision* (1842); and Abbot, *Sight and Touch* (1864); with the last may be compared Monck, *Space and Vision*. (R. AD.)

BERKHAMPSTEAD, Great, a market-town of England, in the county of Herts, 26 miles N.W. of London, on the Junction Canal and the North-Western Railway. It has a spacious cruciform church, with a tower of the 16th century, a market-house, erected in 1860, which includes a corn exchange and a library, a grammar school, a free school, several almshouses, a jail, &c. Straw-plaiting and the manufacture of small wooden wares are the principal industries. The town is of considerable antiquity, and was one of the royal residences under the Mercian kings, a distinction which it again enjoyed under Henry II. The castle, at that time a fortress of some importance, was bestowed on the Black Prince, and since then the manor has remained an apanage of the successive princes of

Wales. The poet Cowper was born in the rectory in 1731. Population in 1872, 4083.

For Map, see Oxford.
BERKSHIRE, one of the south-eastern counties of England, bounded on the N.E. by Buckinghamshire, from which it is separated by the Thames; N. by Oxfordshire and a small portion of Gloucester; W. by Wilts; S. by Hants; and S.E. by Surrey. It is of a very irregular figure, extending from east to west fully 60 miles; while from north to south, in its widest part, it is about 35 miles, and in its narrowest part, at Reading, not more than 7. Area, 450,132 acres.

In respect to the character of its surface and soil, the county may be conveniently regarded as consisting of two divisions—the eastern, containing the six districts east and inclusive of Bradfield, and the western, embracing the remaining six districts. The surface of the eastern division is partly level and partly undulating, and in many places, as at Windsor, it is beautifully wooded. The highest ground is at Bagshot Heath, a sandy plateau 460 feet high, at the south-east corner of the county. The character of the soil in the eastern division is considered poorer than in the west, and consists mostly of blue clay and gravel, resting on a chalk formation. In this division, tillage, dairy farming, and manufacturing are more extensively pursued than in the other, and it is consequently more thickly populated. The western or upland division contains a large proportion of elevated ground, and its soil is a reddish gravelly loam. Here a line of chalk hills, reaching from Aldworth to Ashbury (which includes the Ilsley Downs), runs east and west, separating the two fertile valleys of the Kennet and the Thames. Another range of chalk downs, known as the Cuckamsley Hills, extends from the neighbourhood of Wantage to the border of Wiltshire, the highest point being White-Horse Hill, 893 feet high. In this part of the county the rearing of sheep is largely carried on, while in the district of Hungerford, which is situated in the basin of the Kennet, the soil allows a large breadth of tillage, and a greater number of persons are engaged in agricultural pursuits there than any other district in the county.

Wheat and beans are extensively cultivated; and a species of peat found on the banks of the Kennet yields ashes that are of great value to the soils near that river In the vales of Kennet and White-Horse dairy farming predominates. Near Faringdon pigs are extensively reared, and the breed is celebrated. The estate of Pusey, in the district of Faringdon, presents one of the best examples of high class farming, while in the eastern division the model farms in the district of Wokingham, the property of John Walter, Esq., M.P. for the county, may be referred to as the best specimens of the recent improvements in agriculture. Mr Walter's mansion at Bearwood, too, is an instance of a baronial residence seldom equalled in extent and admirable disposition.

Few parts of England are better supplied with the facilities of water communication than the county of Berks. It is connected by means of the Thames with London on the one hand, and on the other with the Severn at two separate points on that river;—one through the Thames and Severn canal, some miles below Gloucester the other through the River Kennet and the Kennet and Avon canal by Bath and Bristol. Besides the navigable rivers, it enjoys the benefit of the Wilts and Berks canal, which connects the Thames at Abingdon with the Avon at Trowbridge in Wiltshire, and communicates with the Kennet and Avon canal. The other rivers, which all finally fall into the Thames, are the Ock, the Loddon, the Enborne, and the Lambourn.

The turnpike roads are generally good. The principal of these are the roads from London to Bath and Oxford, both of which enter the county at Maidenhead, and soon afterwards separate, the former running S.W. to Reading, the latter nearly N.W. to Henley. Eight branches of railway intersect the county, viz., the Great Western, from Maidenhead to Reading, and from Reading to Shrivenham; the branch from Didcot to Hincksey and Oxford; the Berks and Hants railway branches from Reading to Mortimer and Basingstoke, and from Reading to Newbury and Hungerford; the Reading, Guildford, and Reigate line; and the Reading, Wokingham, and Staines branch of the South-Western Railway.

Berkshire is not a manufacturing county, although the woollen manufacture was introduced here as long ago as the time of the Tudors. There are some paper-mills, particularly in the neighbourhood of Newbury, and an extensive biscuit manufactory at Reading. The chief trade consists in agricultural produce.

From its vicinity to the metropolis, the salubrity of the climate, and the general beauty of the country, few counties have more numerous seats of the nobility and gentry than are to be found in Berkshire. Among these stands preeminent the royal castle of Windsor, the favourite residence of our monarchs during many centuries. There may also be mentioned Wytham Abbey (earl of Abingdon); Ashdown Park and Hamstead Marshall (earl of Craven); Coleshill (earl of Radnor); Shrivenham House (Viscount Barrington); Easthampstead Park (marquis of Downshire); Englefield House (R. Benyon, Esq., M.P.); Aldermaston House (Higford Burr, Esq.); South Hill Park (Rt. Hon. Sir W. G. Hayter, Bart.); Pusey House (Sydney Bouverie Pusey, Esq.); Bearwood (John Walter, Esq., M.P.); and Lockinge House (Col. Loyd Lindsay, V.C., M.P.)

The county comprises 20 hundreds, 6 municipal boroughs, and 142 parishes, besides 14 others chiefly or partially included in Berks. The county is in the diocese of Oxford and the ecclesiastical province of Canterbury. It forms an archdeaconry by itself, and is divided into the four rural deaneries of Abingdon, Newbury, Reading, and Wallingford. It is in the Oxford circuit, and the assizes are held at Reading. County courts are held at Abingdon, Faringdon, Hungerford, Maidenhead, Newbury, Reading, Wallingford, Wantage, Windsor, and Wokingham.

Berkshire returns 3 members to parliament for the county 2 for the borough of Reading, and 1 for each of the boroughs of Abingdon, Wallingford, and Windsor.

At the three decennial enumerations the population of the county was as follows:—

	Houses.	Population.	Increase per cent.
1851	35,075	170,065	5
1861	37,324	176,256	4
1871	41,821	196,475	10

The chief increase has taken place in the eastern division of the county, where the density of the population amounted in 1871 to about 1 person to 1·5 acre, while in the western it was 1 person to 3·5 acres. The principal towns in the county are Reading (pop. 32,324), Windsor (11,769), Newbury (6602), Maidenhead (6173), Abingdon (5799), Wantage (3295), and Wallingford (2972). The population of the parliamentary districts differs from the above, as these districts include persons located beyond the boundaries of the boroughs.

Antiquities, both Roman and Saxon, are numerous in various parts of this county. Watling Street enters Berkshire from Bedfordshire at the village of Streatley, and leaves it at Newbury. Another Roman road passes from Reading to Newbury, where it divides into two branches, one passing to Marlborough in Wiltshire, and the other to Cirencester in Gloucestershire. A branch of Icknield Street passes from Wallingford to Wantage. Near Wan-

tage is a Roman camp, of a quadrangular form; and there are other remains of encampments at East Hampstead near Wokingham, at Pusey, on White-Horse Hill, and at Sinodun Hill, near Wallingford. At Lawrence Waltham there is a Roman fort, and near Denchworth a fortress said to have been built by Canute the Dane, called Cherbury Castle. Barrows are very numerous in the downs in the N.W. of the county, particularly between Lambourn and Wantage. Dragon Hill is supposed to have been the burying-place of a British prince called Uther Pendragon, and near to it is Uffington Castle, supposed to be of Danish construction. On White-Horse Hill, in the same vicinity, is the rude figure of what is called a horse, although it bears a greater resemblance to a greyhound. It has been formed by cutting away the turf and leaving the chalk bare. It occupies nearly an acre of land, and is said to have been executed by Alfred to celebrate a victory over the Danes in the reign of his brother Ethelred, in the year 872. This memorial, not having been "scoured" for many years, is nearly obliterated by the growth of the turf over the chalk. It is part of the property of the earl of Craven.

Berkshire comprehended the principality inhabited by the *Atrebates*, a tribe of people who originally migrated from Gaul. Under the Romans it formed part of *Britannia Prima*, and during the Saxon heptarchy was included in the kingdom of the West Saxons. When Alfred divided the country into shires, hundreds, and parishes, it obtained the name of *Berocsoire*, which was subsequently changed to that which it now bears. It was frequently the scene of military operations from the time of Offa down to the troubles in the reign of Charles I. During the civil war two battles were fought at Newbury. In 1643, after a siege, Reading was taken by the Parliamentary forces, and the Royalist party were expelled from the whole of the county except Wallingford.

BERLIN is the chief city of the province of Brandenburg, the capital of the kingdom of Prussia, and since 1871 the metropolis of the German empire. It is situated in 52° 30′ 16″ N. lat. and 13° 23′ 16″ E. long., and lies about 120 feet above the level of the Baltic. Its longest day is 16 hours 47 minutes; its shortest day is 7 hours 36 minutes. Its average annual temperature is 48 2° Fahr., the maximum recorded heat being 99 5° in 1819, and the maximum cold − 16 1° Fahr. in 1823. The average rainfall is 21 74 Prussian inches, and Berlin has on the average 120 rainy, 29 snowy, and 17 foggy days in a year.

The city is built on what was originally in part a sandy and in part a marshy district on both sides of the River Spree, not far from its junction with the Havel, one of the principal tributaries of the Elbe. By its canals it has also direct water communication with the Oder. The Spree rises in the mountain region of Upper Lusatia, is navigable for the last 97 English miles of its course, enters Berlin on the S.E. as a broad sluggish stream, retaining an average width of 420 feet, and a depth of 6 or 7 feet, until it approaches the centre of the city, where it has a sudden fall of 4 feet, and leaves the city on the N.W., after receiving the waters of the Panke, again as a dull and sluggish stream, with an average width of only 160 feet, but with its depth increased to from 12 to 14 feet. Within the boundaries of the city it feeds canals, and divides into branches, which, however, reunite. The river, with its canals and branches, is crossed by about 50 bridges, of which very few have any claim to architectural beauty. Among these latter may be mentioned the Schlossbrücke, built after designs by Schinkel in the years 1822-24, with its eight colossal figures of white marble, representing the ideal stages of a warrior's career. The statues are for the most part of high artistic merit. They stand on granite pedestals, and are the work of Drake, Wolff, and other eminent sculptors. The Kurfürstenbrücke is another bridge which merits notice, on account of the equestrian bronze statue of the Great Elector by which it is adorned.

The etymology of the word "Berlin" is doubtful. Some derive it from Celtic roots—*ber*, small, short, and *lyn*, a lake. Others regard it as a Wend word, meaning a free, open place. Others, again, regard it as coming from the word *werl*, a river island. Professor Paul Cassel, in a recently published dissertation, derives it from the German word "Brühl," a marshy district, and the Slavonic termination "in;" thus Bruhl, by the regular transmutation Bürhl (compare Germ. *bren*-nen and Eng. burn), Burhlin. The question is likely to remain in the stage of more or less probable conjecture. Name.

Similar obscurity rests on the origin of the city. The hypotheses which carried it back to the early years of the Christian era have been wholly abandoned. Even the Margrave Albert the Bear (d. 1170) is no longer unquestionably regarded as its founder, and the tendency of opinion now is to date its origin from the time of his great-grandsons, Otho and John. When first alluded to, what is now Berlin was spoken of as two towns, Coln and Berlin. The first authentic document concerning the former is from the year 1237, concerning the latter from the year 1244, and it is with these dates that the trustworthy history of the city begins. Fidicin, in his *Diplomatische Beiträge zur Geschichte der Stadt Berlin*, vol. iii., divides the history of the town, from its origin to the times of the Reformation into three periods. The first of these, down to the year 1307, is the period during which the two towns had a separate administration; the second from 1307 to 1442, dates from the initiation of the joint administration of the two towns to its consummation. The third period extends from 1442 to 1539, when the two towns embraced the reformed faith. Origin.

In the year 1565 the town had already a population of 12,000. About ninety years later, after the close of the Thirty Years' War, it had sunk to 6000. At the death of the Great Elector in 1688, it had risen to 20,000. The Elector Frederick III., afterwards King Frederick I., sought to make it worthy of a royal "residence," to which rank it had been raised in 1701. From that time onwards Berlin grew steadily in extent, splendour, and population. Frederick the Great found it, at his accession in 1740, with 90,000 inhabitants. At the accession of Frederick William IV. in 1840 it had 331,894, and in the month of July 1874, thirty-four years later, the population had nearly trebled, the exact numbers in that year being 949,144. The two original townships of Coln and Berlin have grown into the sixteen townships into which the city is now divided, covering about 25 English square miles of land, and Berlin now takes its place as the fourth, perhaps the third, greatest city in Europe, surpassed only by London, Paris, and possibly Vienna. Its importance is now such that a bill, at present submitted by the Government to the consideration of the Legislature, proposes to raise it to the rank of a province of the kingdom. Progress.

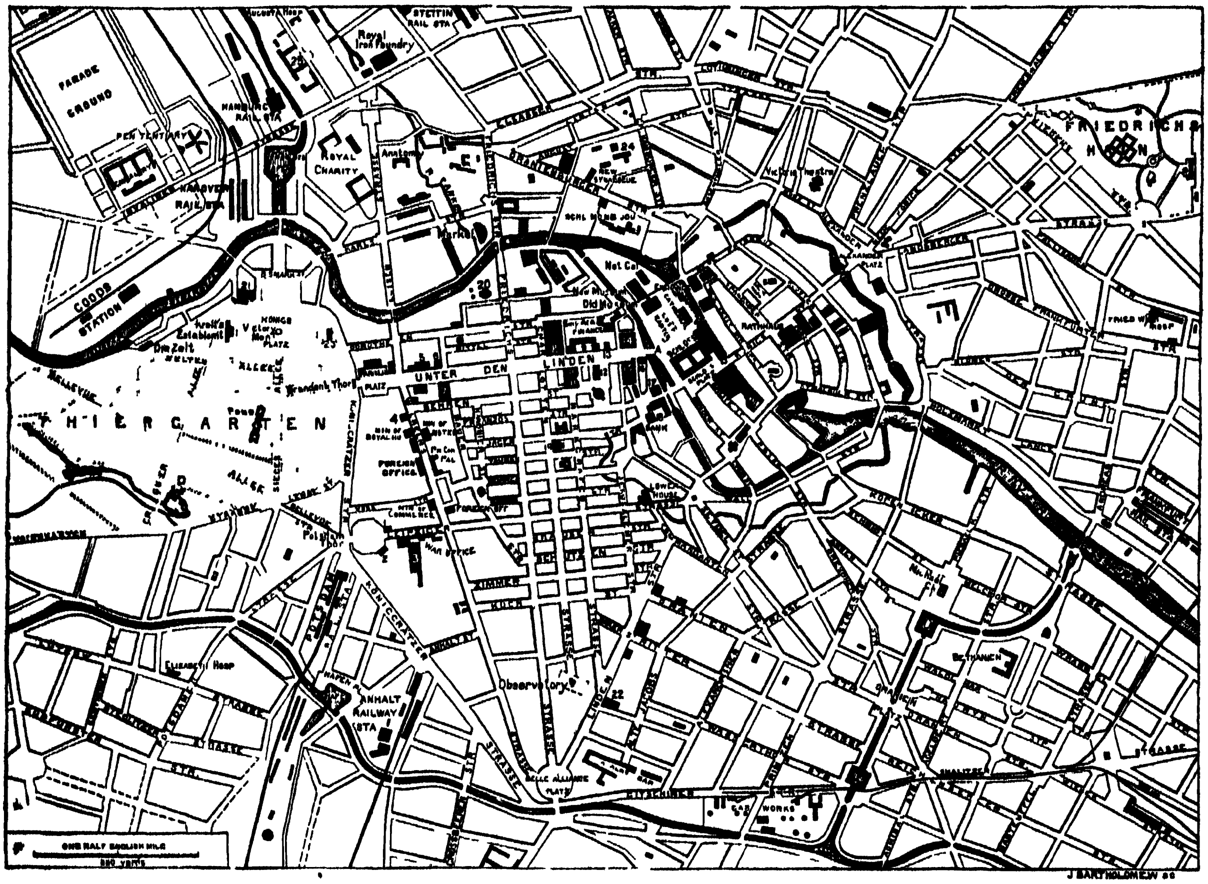
Progress and prosperity have, however, been chequered by reverses and humiliations. The 17th century saw the Imperialists and Swedes, under Wallenstein and under Gustavus Adolphus, as enemies, within its walls; the 18th century, the Austrians and Russians, during the Seven Years' War; the 19th century, Napoleon I and the French; and the year 1848 witnessed the bloody scenes of the March Revolution. But the development of constitutional government, and the triumphs of 1866 and 1870, have wiped out the memory of these dark spots in the history of the Prussian capital.

The town has grown in splendour as it has increased in numbers. Daniel, in the fourth volume of his *Handbook*

Public buildings.

of Geography, gives the number of its public buildings as 700. Of these, its churches are the structures which lay claim to the highest antiquity, four of them dating from the 13th and 14th centuries. But in respect of its churches, both in their number and their beauty, Berlin is, relatively speaking, probably the poorest of the capitals of Christendom. It has only 48 churches and chapels belonging to the State Church, 5 Roman Catholic churches and chapels, 8 foreign and free chapels, and 3 synagogues, to satisfy the religious wants of a million of people. Nor are these over-filled. Dr Schwabe, the statistician, fixes the number of actual worshippers in all the churches on an average Sunday at less than 2 per cent. of the entire population. On the 1st of December 1871 the different creeds were found to be represented in the following proportions:—732,351 were Protestants of the State Church, 2570 Dissenters, 51,517 Roman Catholics, 36,015 Jews, 34 of non-Christian creeds, 3854 persons whose creed was uncertain.

In secular public buildings Berlin is very rich. Entering the city at the Potsdam Gate, traversing a few hundred yards of the Leipzigerstrasse, turning into the Wilhelmstrasse, and following its course until it reaches the street Unter den Linden, then beginning at the Brandenburg Gate and going along the Unter den Linden until its termination, there will be seen within the limits of half an hour's walk the following among other buildings, many of them of great architectural merit:—The Admiralty, the Upper House of the Prussian Legislature, the Imperial Parliament, the War Office, the residence of the Minister of Commerce, the palaces of Prince Carl and the Princes Pless and Radziwill, the Foreign Office, the Imperial Chancery, the palaces of the Ministers of the Royal House and of Justice, the palaces of the Princes Alexander and George, the Brandenburg Gate, the Royal School of Artillery and Engineering, the residences and offices of the Ministers of the Interior and of Worship, the Russian Embassy, the Great Arcade, the Netherland Palace and the palace of the Emperor, the Royal Academy, the University, the Royal Library, the Opera, the Arsenal, the palace of the Crown Prince, the palace of the Commandant of Berlin, the Castle Bridge, the Academy of Architecture, the Castle, the Cathedral, the Old and New Museums, and the National Gallery. At a short distance from this line are the Exchange, the Rathhaus, the Mint, the Bank, and the Royal Theatre. Further away are the various barracks, the palace of the general staff, and the eight railway termini. Berlin differs from other great capitals in this respect, that with the exception of the castle,—a large building enclosing two courts, and containing more than 600 rooms, and which dates back in its origin to the 16th century,—all its public buildings are comparatively modern, dating in their present form from the 18th and 19th centuries. The public buildings and monuments which render it famous, such as the palaces, museums, theatre, exchange, bank, rathhaus, the Jewish synagogue, the monuments and columns of victory, date almost without exception from later



Plan of Berlin.

A, Schloss Brücke (Castle Bridge).
B, Lange or Kurfürsten Brücke.
C, Monument to Frederick the Great.
D, Monument to Frederick William III.
1. British Embassy
2. Admiralty
3. Industrial (Gewerbe) Museum.
4 Palace of Princes Alexander and George.
5. Ministry of the Interior.
6. Aquarium
7. Russian Embassy.
8. Royal Academy.
9 University.
10 Palace of the Emperor.
11 Royal Library
12 Opera
13 Königswache.
14. Zeughaus (Arsenal)
15 Palace of the Crown Prince.
16. Palace of the Commandant of Berlin.
17. Bauakademie (Architecture).
18. Münze (Mint).
19 Royal Theatre.
20 Circus (Renz)
21 Palace of the General Staff.
22 Kammergericht (Chamber).
23. Count Raczynski's Picture Gallery.
24 Catholic Hospital.
25. Infirmary.

than 1814, the close of the great conflict with Napoleon I. The Exchange, finished in 1863, at a cost of £180,000 sterling; the Synagogue, a proud building in Oriental style, finished in 1866, at a cost of £107,000; and the Rathhaus, finished in 1869, at a cost of £500,000 sterling, including the land on which it stands, are the most recent of its great buildings. The New National Gallery is nearly completed, and the Imperial Bank is being rebuilt. It is probable that no city in the world can show so large a number of fine structures so closely clustered together.

Up to a very recent date Berlin was a walled city. Those of its nineteen gates which still remain have only an historical or architectural interest. The principal of these is the Brandenburg Gate, an imitation of the Propylæa at Athens. It is 201 feet broad and nearly 65 feet high. It is supported by twelve Doric columns, each 44 feet in height, and surmounted by a car of victory, which, taken by Napoleon to Paris in 1807, was brought back by the Prussians in 1814. It has recently been enlarged by two lateral colonnades, each supported by 16 columns.

Streets. The streets, about 520 in number, are, with the exception of the districts in the most ancient part of the city, long, straight, and wide, lined with high houses, for the old typical Berlin house, with its ground floor and first floor, is rapidly disappearing. The Unter den Linden is 3287 feet long by 160 broad The new boulevard, the Königgratzerstrasse, is longer still, though not so wide. The Friedrichstrasse and the Oranienstrasse exceed 2 English miles in length. The city has about 60 squares. It has 25 theatres and 14 large halls for regular entertainments. It has an aquarium, zoological garden, and a floral institution, with park, flower, and palm houses.

Hospitals. It has several hospitals, of which the largest is the Charité, with accommodation for 1500 patients. The Bethany, Elizabeth, and Lazarus hospitals are attached to establishments of Protestant deaconesses. The St Hedwig's hospital is under the care of Roman Catholic sisters. The Augusta hospital, under the immediate patronage and control of the empress, is in the hands of lady nurses, who nurse the sick without assuming the garb and character of a religious sisterhood. The people's parks are the Humboldt's Hain, the Friedrich's Hain, the Hasenheide, and, above all, the Thiergarten, a wood covering 820 Prussian acres of ground, and reaching up to the Brandenburg Gate.

Statistics of population. As has been seen, the population has trebled itself within the last 34 years, naturally not so much by the excess of births over deaths, as by an unbroken current of immigration. In 1873 the births were 35,954, the deaths 26,427, leaving an excess of 8527 births. But the increase in the population of the city in the same year was 50,184, leaving 41,657 as the increase through the influx from without. It will thus be seen at a glance that only a minority of the population are native Berliners. In the census of 1867 it was found that, taking the population above 20 years of age, only one-third were natives of the city. The immigration is almost exclusively from the Prussian provinces, and among these principally from Brandenburg and from the eastern and north-eastern provinces. In 1871 it was found that out of every 10,000 inhabitants, 9725 were Prussian subjects, 165 were from other German states, 55 from foreign lands, and 47 were of a nationality not ascertained. The foreign element almost vanishes, and the German element is represented principally by the north, so that in blood and manners Berlin remains essentially a north-eastern German city, *i.e.*, a city in which German, Wend, and Polish blood flows commingled in the veins of the citizens. In past times Berlin received a strong infusion of foreign blood, the influence of which is perceptible to the present day in its intellectual and social life. Such names as Savigny, Lancizolle, De la Croix, De le Coq, Du Bois-Reymond, tell of the French refugees who found a home here in the cold north when expelled from their own land. Daniel, in his *Geography*, vol. iv. p. 155, says that there was a time when every tenth man in the city was a Frenchman. Flemish and Bohemian elements, to say nothing of the banished Salzburgers, were introduced in a similar manner. Add to these the 36,013 Jews now resident in the city, and the picture of the commingled races which make up its population is pretty complete.

The 826,341 inhabitants of the city were found at the census of 1871 to be living in 14,478 dwelling-houses, and to consist of 178,159 households. These numbers show that the luxury of a single house for a single family is rare, and this holds good also of the wealthier classes of the people. These numbers fall far short of the present (1875) number of houses and of households, as will be seen from the fact that the value of the household property of the city in 1874 exceeded that of 1871 by £18,000,000 sterling, of which the greatest part falls to newly-built houses or houses enlarged. In 1871 the average number of persons comprised in a household was found to be 4·6, the number of households dwelling in a house 12·3, and the number of persons dwelling in a house 57·1. These numbers throw light on the moral and social life of the city, and compared with the past, show the change in the domestic habits of the people. In 1540 the average number of inmates in a house was 6, in 1740 it was 17, in 1867 it had risen to 32, and in 1871 to 57. Between the years 1864 and 1871 the one-storied houses of the city decreased 8 per cent., the two and three-storied houses 4½ per cent., while the number of four-storied houses increased 11 per cent., and the five-storied and higher houses 50 per cent. With the increase of high houses, the underground cellar dwellings, which form so striking a feature in the house architecture of the city, increase in a like proportion, and these and the attics are the dwellings of the poor. In 1867 there were 14,292 such cellar dwellings, in 1871 they had increased to 19,208. Taking the average of 1867—4 inmates to a cellar dwelling—we get 76,832 persons living under ground. In 1871 there were 4565 dwellings which contained no room which could be heated. This class of dwelling had doubled between the two census years of 1867 and 1871. Taking 3 inmates (the ascertained average of 1867) to such a dwelling, we have 13,695 persons who pass the winter in unheated dwellings, in a climate where the cold not unfrequently sinks below the zero of Fahrenheit. Of the remaining dwellings of the city, 95,423 had only one room which could be heated. This number, at 4 persons to a dwelling, give us an insight into the domestic life of 381,692 of the inhabitants of the city; that is, with the 13,695 persons mentioned above, of nearly half the population. Such dwellings engender no feeling of home, and the habits of the people are in a certain sense nomadic. In 1872, 74,568 changes of dwelling took place, involving an expense at a very moderate calculation of £158,900. In the poorer townships there were 70 removals to every 100 dwellings!

The rate of mortality is high. In 1873, a favourable year, it was 28 to every 1000 of the population. Taking the deaths as a whole, 58 per cent. were of children under 10 years of age. The rate of mortality is on the increase. Professor Virchow, in a report to the municipal authorities, stated that, dividing the last 15 years into periods of 5 years each, the general mortality in each of the three periods was as 5, 7, 9. The mortality of children under 1 year in the same three periods was as 5, 7, 11; that is, it had more than doubled. In the year 1872, out of 27,800 deaths, 11,136 were of children under 1 year.

The city is well supplied with water by works constructed by an English company, which have now become

the property of the city. English and German companies supply the city with gas. A system of underground drainage is at present in process of construction. Internal communication is kept up by means of tramways, omnibuses, and cabs. In 1873 there were 54 tram-carriages, 185 omnibuses, and 4424 cabs licensed, served by 10,060 horses.

Police.

Berlin is governed by the president of police, by the municipal authorities, and in military matters by the governor and commandant of the city. The police president stands under the minister of the interior, and has the control of all that stands related to the maintenance of public order. The municipal body consists of a burgomaster-in-chief, a burgomaster, a body of town councillors (Stadträthe), and a body of town deputies (Stadtverordnete). For municipal purposes the city is divided into 16 townships and 210 districts. For police purposes the *work* is divided into six departments, and an extra department for the fire brigade and street cleaning, and the *town* into six larger and fifty smaller districts. At the head of each larger district is a police captain, at the head of each smaller district a police lieutenant.

Schools.

With the exception of a few of the higher schools, which are under the direct supervision of the provincial authorities, the Berlin schools are either under the direct supervision of the municipal body or of its committee for school purposes. The schools, public and private, are divided into higher, middle, and elementary. In 1872 there were 24 higher public schools. Of these, 10 were gymnasia or schools for the highest branches of a learned education. In these schools there were 138 classes and 5073 pupils, of whom 2142 were over, and 2931 under, 14 years of age. The second class of high schools, the so-called Realschulen, give instruction in Latin, but otherwise devote almost exclusive attention to the departments of mathematics, science, history, modern languages, and the requirements of the higher stages of general or commercial life. Of this class of school there were also 10, with 143 classes, 5770 pupils, of whom 1931 were over, and 3839 under, 14 years of age. The remaining 4 high schools were for girls, with 54 classes, 2522 pupils, of whom 529 were over, and 1993 under, 14 years of age. In addition to these public schools there were 7 higher schools for boys, with 55 classes and 2098 pupils, and 36 higher schools for girls, with 243 classes and 6629 pupils.

Within the last five years (1875) no new school of this class has been established, but several are in process of erection. Between 1869 and 1873 the city voted about £328,747 sterling for the purchase of sites, and for enlarging and rebuilding schools of this class; and the sum still required for schools of this class, up to 1877, is £352,500 sterling.

The total number of schools of all sorts, higher, middle, and elementary, public and private, in 1872, was 232, with 1072 boys' classes, 1009 girls' classes, and 4 mixed classes—together, 2085; attended by 50,316 boys, 44,959 girls—together, 95,275 children, of whom 7309, or 7·35 per cent., were over 14 years of age. The extent to which the schools are used under the law of compulsory education is very difficult to determine. In 1867 there were 103,383 children of the school age, but only 71,814, or 69·5 per cent., were in the schools. Dr Schwabe, by a criticism of these numbers, reduces the percentage of non-attendance to 13 per cent., and maintains that even these are not all to be regarded as absolutely without instruction. In 1871 it was found that out of every 10,000 persons of 70 years of age and upwards, there were 1529 who could neither read nor write; and that out of a like number from 60 to 70, there were 860; 50 to 60, 446; 40 to 50, 234; 30 to 40, 158; 25 to 30, 155; 20 to 25, 71; 15 to 20, 58; and from 10 to 15, 48.

The scholastic life of Berlin culminates in its university, which is of course not a municipal, but a national institution. It is, with the exception of Bonn, the youngest of the Prussian universities, but the first of them all in influence and reputation. It was founded in 1810. Prussia had lost her celebrated university of Halle, when that city was included by Napoleon in his newly created "kingdom of Westphalia." It was as a weapon of war, as well as a nursery of learning, that Frederick William III., and the great men whose names are identified with its origin called it into existence, for it was felt that knowledge and religion are the true strength and defence of nations. William v. Humboldt was at that time at the head of the educational department of the kingdom, and men like Fichte and Schleiermacher worked the popular mind. It was opened on the 15th of October 1810. Its first rector was Schmalz; its first deans of faculty, Schleiermacher, Biener, Hufeland, and Fichte. Within the first ten years of its existence it counted among its professors such names as De Wette, Neander, Marheineke; Savigny, Eichhorn; Bockh, Bekker, Hegel, Raumer, Wolff, Niebuhr and Buttmann. Later followed such names as Hengstenberg and Nitzsch; Homeyer, Bethman-Hollweg, Puchta, Stahl, and Heffter; Schelling, Trendelenburg, Bopp, the brothers Grimm, Zumpt, Carl Ritter; and at the present time it can boast of such names as Twesten and Dorner, Gneist and Hinschius; Langenbeck, Bardeleben, Virchow, and Du Bois-Reymond; von Ranke, Mommsen, Curtius, Lepsius, Hoffman the chemist, and Kiepert the geographer. Taking ordinary, honorary, and extraordinary professors, licensed lecturers (*privatdocenten*), and readers together, its present professorial strength consists of 15 teachers in the faculty of theology, 14 in the faculty of law, 63 in the faculty of medicine, and 96 in the faculty of philosophy—together, 188. The number of matriculated and unmatriculated attendants on the various lectures averages 3000 in the summer term, and 3500 in the winter. During the last two or three years, however, the number has been steadily decreasing. Berlin, in point of numbers, still stands at the head of the Prussian universities, but no longer of the German universities, being now outstripped by Leipsic.

In addition to its schools and its university, Berlin is rich in institutions for the promotion of learning, science, and the arts. It has a Royal Academy of Sciences, with 46 members, 23 in the class of physics and mathematics, and 23 in the class of philosophy and history. It was founded on the 11th of June 1700, and the name of Leibnitz is associated with its foundation. It was raised to the rank of a Royal Academy by Frederick the Great in 1743. Berlin has also a Royal Academy of Arts, consisting of 39 ordinary members (1875), under the immediate protection of the king, and governed by a director and a senate, composed of 15 members in the departments of painting, sculpture, architecture, and engraving, and 4 members in the section for music. Berlin has also its academy for vocal music, and its royal high school for music in all its branches, theoretical and applied, and learned bodies and associations of the most various kinds. It has 9 public libraries, at the head of which stands the royal library, with 710,000 volumes and 15,000 manuscripts. In addition to these, there are 15 people's libraries established in various parts of the city.

Berlin possesses eight public museums, in addition to the Royal Museums and the National Gallery. The Royal Museums are the Old and the New Museums. The former, which stands on the north-east side of the Lustgarten, facing the castle, is the most imposing building in Berlin. It was built in the reign of Frederick William III., from designs by Schinkel. Its portico, supported by 18 colossal Ionic columns, is reached by a wide flight of steps. The museum covers 47,000 square feet of ground, and is 276

feet long, by 170 feet wide and 61 feet high. The back and side walls of the portico are covered with frescoes, from designs by Schinkel, executed under the direction of Cornelius, and representing, in mythical and symbolical figures, the world's progress from shapeless and chaotic to organic and developed life. The sides of the flight of steps support the well-known equestrian bronze groups of the Amazon by Kiss, and the Lion-slayer by Albert Wolff. Under the portico are monuments of the sculptors Rauch and Schadow, the architect Schinkel, and the art critic Winckelmann. The interior consists of a souterrain, containing the collection of antiquities, and of a first floor, entered from the portico through bronze doors of artistic merit, made after designs by Stüler, weighing 7½ tons, and executed at a cost of £3600. This floor consists of a rotunda, and of halls and cabinets of sculpture. The second floor, in a series of cabinets running round the entire building, contains the national collection of paintings. These are divided into three classes,—the Italian, French, and Spanish; the Dutch, Flemish, and German; and the Byzantine, Italian, Dutch, and German pictures down to the end of the 15th century—each of the classes being chronologically arranged. The gallery, then containing 1300 paintings, was enriched in 1874 by the valuable pictures of the Suermondt gallery, purchased by the nation at a cost of £51,000. The Suermondt gallery was rich in pictures of the old Netherland and German schools, and of the Dutch and Flemish schools. It also contained a few Spanish, Italian, and French pictures.

The New Museum is connected with the Old Museum by a covered corridor. In its interior arrangements and decoration it is undoubtedly the most splendid structure in the city. Like the Old Museum, it has three floors. The lowest of these contains the Ethnographical and Egyptian Museums and the Museum of Northern Antiquities. In the first floor, plaster casts of ancient, mediæval, and modern sculpture are found in thirteen halls and in three departments. On the walls of the grand marble staircase, which rises to the full height of the building, Kaulbach's renowned cyclus of stereochromic pictures is painted, representing the six great epochs of human progress, from the confusion of tongues at the Tower of Babel and the dispersion of the nations to the Reformation of the 16th century. The uppermost story contains the collection of engravings and the gallery of curiosities.

The National Gallery is an elegant building, after designs by Stüler, situated between the New Museum and the Spree, and is intended to receive the collection of modern paintings now exhibited provisionally in the apartments of the Academy.

Monuments. The public monuments are the equestrian statues of the Great Elector on the Lange Brucke, erected in 1703, Rauch's celebrated statue of Frederick the Great, "probably the grandest monument in Europe," opposite the emperor's palace, Unter den Linden; and the statue of Frederick William III. in the Lustgarten. In the Thiergarten is Drake's marble monument of Frederick William III.; and in the neighbouring Charlottenburg, Rauch's figures of the same king and the Queen Louise in the mausoleum in the Park. A second group of monuments on the Wilhelm's Platz commemorates the generals of the Seven Years' War; and a third, in the neighbourhood of the Opera, the generals who fought against Napoleon I. On the Kreuz berg, the highest spot in the neighbourhood of Berlin, a Gothic monument in bronze was erected by Frederick William III. to commemorate the victories of 1813–15; and in the Königsplatz the present emperor has erected a column of victory in honour of the triumphs of 1864, 1866, and 1870. This monument rises to the height of 197 feet, the gilded figure of Victory on the top being 40 feet high. Literature, science, and art are represented in different parts of the city by statues and busts of Rauch, Schinkel, Thaer, Beuth, Schadow, Winckelmann, Schiller, Hegel, Jahn; while the monuments in the cemeteries and churches bear the names of distinguished men in all departments of political, military, and scientific life.

Publications. Next to Leipsic, Berlin is the largest publishing centre in Germany. In the year 1872 there were 1540 works published in Berlin, of which 20 per cent. had to do with literature, 15 per cent. with philology and pedagogy, 14 per cent. with law and politics, 7 per cent. with history, 6 per cent. were military works, 5 per cent. theological, 5 per cent. had to do with agriculture, and 4 per cent. with medicine. Turning to journals and periodical literature, 265 newspapers and magazines, daily, weekly, or monthly, appeared in the same year. The political journals in Berlin do not, however, sustain the same relation to the political life of Germany as do the political journals of London and Paris to that of England and France.

Manufactures. Berlin is not only a centre of intelligence, but is also an important centre of manufacture and trade. Its trade and manufactures appear to be at present in a transition state—old branches are dying out, and new branches are springing into existence. Direct railway communication between the corn lands of north-eastern Germany, Poland, and Russia on the one hand, and the states of Central and Western Germany on the other, have deprived Berlin of much of its importance as a centre of trade in corn and flour. In like manner the spirit trade and manufacture have suffered. The 20,892,493 litres exported in 1870 had sunk to 9,737,597 litres in 1872. On the other hand, for petroleum, Berlin has become an emporium for the supply of the Mark of Brandenburg, part of Posen, Silesia, Saxony, and Bohemia. Silk and cotton manufacture, which in former times constituted a principal branch of Berlin manufacture, has died out. As late as 1849 Berlin had 2147 silk looms; now it has few or none. Woollen manufacture maintained its ground for a time, occupying about 8000 looms and 11,404 workmen as late as 1861. In 1874 the number of hands employed in spinning and weaving in all branches had sunk to 2918. The chief articles of manufacture and commerce are locomotives and machinery; carriages; copper, brass, and bronze wares; porcelain; and the requisites for building of every description. The manuufacture of sewing-machines has assumed large proportions, from 70,000 to 75,000 being manufactured annually. According to the report of the Government inspector of factories for the city of Berlin, presented to the minister of trade and commerce, the number of persons employed in all the Berlin factories in the year 1874 was 64,466. By a "factory" was understood any wholesale manufacturing establishment employing more than 10 persons. In 1874 there were 1906 such factories at work, employing 51,464 males and 11,004 females above 16 years of age; 1137 males and 760 females under 16 and above 14 years of age; and 66 male and 14 female children under 14 years of age. The manufacture of steam-engines and machinery occupied 14,737 persons; brass-founding, metallic belt and lamp manufacture, 9074; carpentry, joinery, and wood-carving, 4548; printing, 3620; spinning and weaving, 2918; sewing-machines and telegraphic apparatus, 2788; the finer qualities of paper, 2585; porcelain and ware, 1741; dyeing, 1712; gas-works, 1518; tobacco and cigars, 1477; manufacture of linen garments, 1355; pianos and harmoniums, 1198, dressmaking and artificial flowers, 1127; brewing, 1061. None of the other branches found occupation for 1000 persons. The value of the annual exports to the United States of articles of Berlin manufacture has risen to about £1,000,000 sterling. The exports to the Brazils, the Argentine Republic, and

Japan are also increasing. Berlin is growing in importance as a money market and centre of industrial undertakings. The Berlin Cassenverein, through which the banking houses transact their business, passed £1,351,988,967 sterling through its books in 1872, as compared with £644,431,255 sterling in 1871. In 1872, 23 new banking establishments were enrolled in the trade register, with a capital of £7,565,000 sterling, and in the same year 144 new joint-stock companies were enrolled, representing a capital of £18,000,000 sterling Since that time the tide of enterprise has ebbed, but the majority of these undertakings continue to exist.

In the progress of its growth Berlin has lost much of its original character. The numerical relations of class to class have been greatly modified. New political institutions have sprung into existence, of which the Berlin of the early years of Frederick William IV. had not a trace. It has become the seat of a parliament of the realm, and of a parliament of the empire. Manufacture and trade have come to absorb 70 per cent. of the entire population. But these have also changed their character; old branches which constituted a marked feature of its commercial and manufacturing activity have almost suddenly died out, while new branches have with equal rapidity more than supplied their place. While the commercial and manufacturing element has thus increased, other elements have undergone a relative decline. The learned professions and the civil service numbered in 1867 7·9 per cent. of the population. In 1871 the proportion had sunk to 6·11, and since then the percentage has gone on decreasing. In this altered state of affairs Berlin will have to cherish and nurture the scientific, educational, ethical, and religious elements in her life with double care, not only to keep up her old reputation abroad, but also for the purpose of preventing the degeneration of her people at home.

BERLIOZ, HECTOR, by far the most original composer of modern France, was born in 1803 at Côte-Saint-André, a small town near Grenoble, in the department of Isère. His father was a physician of repute, and by his desire our composer for some time devoted himself to the study of the same profession. At the same time he had music lessons, and, in secret, perused numerous theoretical works on counterpoint and harmony, with little profit it seems, till the hearing and subsequent careful analysis of one of Haydn's quartets opened a new vista to his unguided aspirations. A similar work written by Berlioz in imitation of Haydn's masterpiece was favourably received by his friends. From Paris, where he had been sent to complete his medical studies, he at last made known to his father the unalterable decision of devoting himself entirely to art, the answer to which confession was the withdrawal of all further pecuniary assistance. In order to support life Berlioz had to accept the humble engagement of a singer in the chorus of the Gymnase theatre. Soon, however, he became reconciled to his father and entered the Conservatoire, where he studied composition under Reicha and Lesueur. His first important composition was an opera called *Les Francs-Juges*, of which, however, only the overture remains extant. In 1825 he left the Conservatoire, disgusted, it is said, at the dry pedantry of the professors, and began a course of autodidactic education, founded chiefly on the works of Beethoven, Gluck, Weber, and other German masters. About this period Berlioz saw for the first time on the stage the talented Irish actress Miss Smithson, who was then charming Paris by her impersonations of Ophelia, Juliet, and other Shakespearean characters. The young enthusiastic composer became deeply enamoured of her at first sight, and tried, for a long time in vain, to gain the responsive love or even the attention of his idol. To an incident of this wild and persevering courtship Berlioz's first symphonic work, *Episode de la Vie d'un Artiste*, owes its origin. It describes the dreams of an artist who, under the influence of opium, imagines that he has killed his mistress, and in his vision witnesses his own execution. It is replete with the spirit of contemporary French romanticism and of self-destructive Byronic despair. A written programme is added to each of the five movements to expound the imaginative material on which the music is founded. By the advice of his friends Berlioz once more entered the Conservatoire, where, after several unsuccessful attempts, his cantata *Sardanapalus* (1830) gained him the first prize for foreign travel, in spite of the strong personal antagonism of one of the umpires. During a stay in Italy Berlioz composed an overture to *King Lear*, and *Le Retour à la Vie*,—a sort of symphony, with intervening poetical declamation between the single movements, called by the composer a melologue, and written in continuation of the *Episode de la Vie d'un Artiste*, along with which work it was performed at the Paris Conservatoire in 1832. Paganini on that occasion spoke to Berlioz the memorable words: "Vous commencez par où les autres ont fini." Miss Smithson, who also was present on the occasion, soon afterwards consented to become the wife of her ardent lover. The artistic success achieved on that occasion did not prove to be of a lasting kind. Berlioz's music was too far remote from the current of popular taste to be much admired beyond a small circle of esoteric worshippers. It is true that his name became known as that of a gifted though eccentric composer; he also received in the course of time his due share of the distinctions generally awarded to artistic merit, such as the ribbon of the Legion of Honour and the membership of the Institute. But these distinctions he owed, perhaps, less to a genuine admiration of his compositions than to his influential position as the musical critic of the *Journal des Débats* (a position which he never used or abused to push his own works), and to his successes abroad. In 1842 Berlioz went for the first time to Germany, where he was hailed with welcome by the leading musicians of the younger generation, Robert Schumann foremost amongst them. The latter paved the way for the French composer's success, by a comprehensive analysis of the *Episode* in his musical journal, the *Neue Zeitschrift für Musik*. Berlioz gave successful concerts at Leipsic and other German cities, and repeated his visit on various later occasions—in 1852, by invitation of Liszt, to conduct his opera, *Benvenuto Cellini* (hissed off the stage in Paris), at Weimar; and in 1855 to produce his oratorio-trilogy, *L'Enfance du Christ*, in the same city. This latter work had been previously performed at Paris, where Berlioz mystified the critics by pretending to have found one part of it, the "Flight into Egypt," amongst the manuscript scores of a composer of the 17th century, Pierre Ducré by name. Berlioz also made journeys to Vienna (1866) and St Petersburg (1867), where his works were received with great enthusiasm. He died in Paris, March 9, 1869.

Berlioz has justly been described as the French representative of musical *Romanticism*, and his works are in this respect closely connected with the contemporary movement in literature known by that name. The affinity between him and Victor Hugo, for instance, is undeniable, and must be looked for deeper than in the fantastic eccentricities and breaches of the established form common

to both. His ready acknowledgment of congenial aspirations in foreign countries, so adverse to French natural prejudice, may be cited as another essentially "romantic" feature in Berlioz's character. In his case, however, the predilection for English literature, as shown in the choice of several of his most important subjects from Shakespeare, Byron, and Walter Scott, may be to some extent explained from his connection with Miss Smithson, a striking instance of the relation between life and art in a man of high creative faculty.

The second powerful element in Berlioz's compositions is the influence of Beethoven's gigantic works. The grand forms of the German master's symphonies impressed him with competitive zeal, and what has been described as the "poetical idea" in Beethoven's creations soon began to run riot in the enthusiastic mind of the young medical student. But, in accordance with the aversion of his national character to indistinct ideal notions, he tried to condense the poetical essence of his inspiration in the tangible shape of a story, and in this manner became the father of what is generally called "programme-music." Whether the author of such works as *Harold en Italie*, or the *Episode de la Vie d'un Artiste*, may lay claim to the prophet's cloak is difficult to decide; he must at any rate be accepted as a man strong in his own convictions, "a swallower of formulas," and faithful ally in the great cause of nature *versus* traditional artificiality, of Shakespeare against pseudo-classicism. Under such circumstances we can hardly be surprised at seeing Berlioz appreciated sooner and more lastingly in Germany than in his own country. Schumann and Liszt were, as we have mentioned, at various periods amongst the foremost promoters of his music. We subjoin a list of the more important works by Berlioz not mentioned above, viz., the symphonies *Roméo et Juliette* (1834), and *Damnation de Faust* (1846); the operas *Béatrice et Bénédict* (1862), and *Les Troyens* (1866); a Requiem, and *Tristia*, a work for chorus and orchestra, written on the death of his wife. Of his spirited literary productions we mention his *Voyage musical en Allemagne et en Italie* (1845), *Les Soirées d'Orchestre* (1853), *A travers Chant* (1862), and his incomparable *Traité d'Instrumentation* (1844). The characteristics of Berlioz's literary style are French *verve* and *esprit*, occasionally combined with English humour and German depth of idea. The time has hardly yet arrived for judging finally of Berlioz's position in the history of his art. His original ideas, his poetical intentions, nobody can deny; the question is whether he possesses genuine creative power to carry out those intentions, and, first of all, that broad touch of nature which leads from suggestive feeling to objective rendering, and which alone can establish a lasting *rapport* between a great artist and posterity. To decide this question the performances of his works have as yet, unfortunately, been too few and far between. In England, particularly, only a very small fraction of his compositions has been heard. (F. H.)

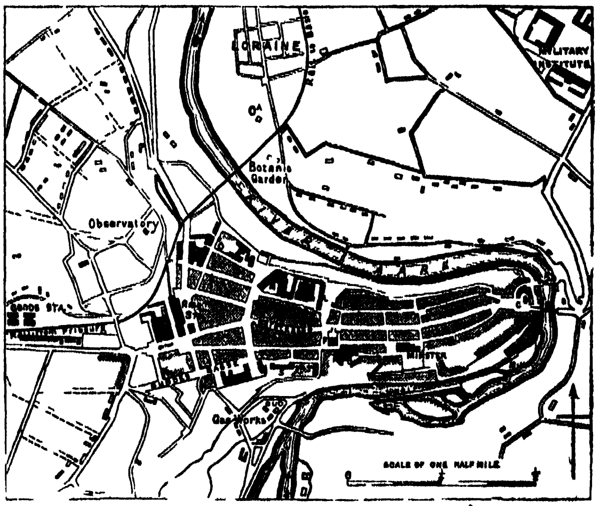
BERMUDAS, Somers's Islands, or Summer Islands, a group in the Atlantic Ocean, the seat of a British colony, in lat. 32° 20′ N. and long. 64° 50′ W., about 600 miles E. by S. from Cape Hatteras on the American coast. They lie to the south of a coral reef or atoll, which extends about 24 miles in length from N.E. to S.W., by 12 in breadth. The largest of the series is Great Bermuda, or Long Island, enclosing on the east Harrington or Little Sound, and on the west the Great Sound, which is thickly studded with islets, and protected on the north by the islands of Somerset, Boaz, and Inland. The remaining members of the group, St George's, Paget's, Smith's, St David's, Cooper's, Nonsuch, &c., lie to the east, and form a semicircle round Castle Harbour. The islands are wholly composed of a white granular limestone of various degrees of hardness, from the crystalline "base rock," as it is called, to friable grit. It seems that they are in a state of subsidence and not of elevation. The caves which usually appear in limestone formations are well represented, many of them running far into the land and displaying a rich variety of stalagmites and stalactites. Among the less ordinary geological phenomena may be mentioned the "sand glacier" at Elbow Bay. The surface soil is a curious kind of red earth, which is also found in ochre-like strata throughout the limestone. It is generally mixed with vegetable matter and coral sand. There is a total want of streams and wells of fresh water, and the inhabitants are dependent on the rain, which they collect and preserve in tanks. The climate of the Bermudas has a reputation for unhealthiness which is hardly borne out, for the ordinary death-rate is only 22 per 1000. Yellow fever and typhus, however, have on some occasions raged with extreme violence, and the former has appeared four times within the space of thirty years. The maximum reading of the thermometer is about 85·8, and its minimum 49,—the mean annual temperature being 70° Fahr., and that of March 65°. Vegetation is very rapid, and the soil is clad in a mantle of almost perpetual green. The principal kind of tree is the so-called "Bermudas cedar," really a species of juniper, which furnishes timber for small vessels. The shores are fringed with the mangrove; the prickly pear grows luxuriantly in the most barren districts; and wherever the ground is left to itself the sage-bush springs up profusely. The citron, sour orange, lemon, and lime grow wild; but the apple and peach do not come to perfection. The loquat, an introduction from China, thrives admirably. The gooseberry, currant, and raspberry, all run to wood. The oleander bush, with all its beauty, is almost a nuisance. The soil is very fertile in the growth of esculent plants and roots; and a considerable trade has grown up within recent years between Bermudas and New York, principally in arrowroot, of excellent quality, onions, Irish potatoes, and tomatoes. Regular steam communication between the island and that city is maintained, the Government subsidizing the vessels. The total value of the export of these articles in 1872 was £64,030. Medicinal plants, as the castor-oil plant, aloe, and jalap, come to great perfection without culture; and coffee, indigo, cotton, and tobacco are also of spontaneous growth. Tobacco curing ceased about 1707. Few oxen or sheep are reared in the colony, a supply being obtained from North America; but goats are kept by a large number of the inhabitants. The ass is the usual beast of burden. The indigenous Mammalia are very few, and the only Reptilia are a small lizard and the green turtle. Birds, however, especially aquatic species, are very numerous,—one of the commonest being the cardinal-grosbeak. The list includes the cat-bird, blue-bird, kingfisher, ground-dove, blue heron, sandpiper, moorhen, tropic bird, and Carolina crake. Insects are comparatively few; but ants swarm destructively in the heat of the year, and a species of ant-lion, a cicada (scissor-grinder), and the chigre or jigger, are common. Fish are plentiful round the coasts, and the whale-fishery was once an important industry. Gold-fish, introduced from Demerara, swarm in the ditches.

There are two towns in the Bermudas, St George's, founded in 1794, and Hamilton, founded in 1790, and incorporated in 1793. The former was the capital till the senate and courts of justice were removed by Sir James Cockburn to Hamilton, which being centrally situated, is much more convenient. The streets of St George's are close and narrow, and the drainage bad. It is a military station, the barracks lying to the east of the town. The population is about 2000. Hamilton, in the Great Bermuda, at the bottom of a bay which is entered by Trenblin's Narrows, consists of an irregular half-street fronting a line of wharves. Its principal buildings include a court-house, a legislative assembly house, a council room, a library (1839), a jail, and a large church. About a mile from the town is Langton, the governor's residence. In Inland Island is situated the royal dockyard and naval establishment. A hospital stands on the highest point, and a lunatic asylum has also been built. The bay is defended by a breakwater. On Boaz Island there is a convict station. A causeway, opened in 1871, runs from St George's through Longbird Island westward, across Castle Harbour. The harbour of St George's has space enough to accommodate the whole British navy; yet, till deepened by blasting, the entrance was so narrow as to render it almost useless. A marine slip was constructed in 1865, with a capacity of 1200 tons. The chief military establishment is at Prospect

Hill. The Government consists of a governor appointed by the Crown, and a privy council of nine members appointed by the governor. The House of Assembly consists of thirty-six members, who receive salaries. The Acts are usually passed for a definite period, and require to be renewed from time to time. Much of the judicial administration is left to unpaid magistrates. The currency of the colony, which had formerly twelve shillings to the pound sterling, was assimilated to that of England in 1842. The colony is ecclesiastically attached to the bishopric of Barbados. Both Presbyterians and Wesleyans are endowed. There are numerous schools, and in 1847 an educational board was established, but the general educational condition is unsatisfactory. Of 2600 children between the ages of five and six, only about 1500 attend school. Sunday schools are of much greater importance than in England, and most of them have libraries. The revenue of the islands in 1872 was £33,256, inclusive of £1500 raised by loan; the gross expenditure was £32,236; and the public debt amounted to £17,330. The population in 1850 was 11,092, of whom 4669 were whites; by the census of 1871 it had increased to 12,121.

The discovery of the Bermudas resulted from the shipwreck of Juan Bermudez, a Spaniard (whose name they now bear), when on a voyage from Spain to Cuba with a cargo of hogs, about the year 1522. Henry May, an Englishman, suffered the same fate in 1593; and lastly, Sir George Somers shared the destiny of the two preceding navigators in 1609. Sir George was the first who established a settlement upon them, but he died before he had fully accomplished his design. In 1612 the Bermudas were granted to an offshoot of the Virginia Company, which consisted of 120 persons, 60 of whom, under the command of Mr Henry More, proceeded to the islands; and an accession of inhabitants was gained during the civil wars, many having sought a refuge from the tyranny of the ruling party in this distant sanctuary. Into the details of the history we cannot enter, but the following items are important. The first source of colonial wealth was the growing of tobacco, which, as already mentioned, grows wild in the islands. In 1726 Berkeley chose the Summer Islands as the seat of his projected missionary establishment. The first newspaper, the *Bermuda Gazette*, was published in 1784. See W. F. Williams, *Hist. and Stat. Account of the Bermudas*, 1848; Godet, *Bermuda, its History, &c.*, 1860.

BERN, or BERNE, a canton of Switzerland, situated between 46° 19′ and 47° 30′ N. lat., and between 6° 50′ and 8° 28′ E. long. It extends from the French and Alsace frontier south-east through the heart of the Confederacy to Valais, by which it is bounded on the S., while it has the cantons of Basel, Soleure, Aargau, Lucerne, Unterwalden, and Uri on the E., and Vaud, Freiburg, Neufchâtel on the W. Bern is the second largest canton of Switzerland, its surface being estimated at 2562 square miles. The population in 1870 amounted to 506,465, of whom 436,304 were Protestants, and 66,015 Catholics, while 1401 were Jews. German was spoken in 83,693 families, and French in 16,646, the latter language prevailing in the N.W. The canton is naturally divided into three regions, in which the climate varies with the elevation. The southern part, called the Oberland, is for its scenery the most attractive part of all Switzerland. Many of the grandest mountains of the Alpine system—such as the Grimsel, the Finsteraarhorn, the Schreckhorn, the Wetterhorn, the Eiger, and the Jungfrau—lie along the frontier chain, and numerous offshoots and valleys of great beauty stretch northward towards the central part of the canton. This latter district consists for the most part of an undulating plain, interspersed with lesser chains and hills,—the soil being fertile and well cultivated. The north is occupied with the ranges of the Jura system. The principal river in the canton is the Aar, which drains by far the larger proportion of its surface, either directly or by means of its numerous tributaries. Of these, the most important are the Saane, from the S.; the Thiele, which forms the outlet of the lakes of Bienne and Neufchâtel; and the Emme, which gives its name to the beautiful Emmenthal. The northern corner of the canton is divided between the basins of the Rhone and the Rhine. On the upper course of the Aar are the two lakes of Brienz and Thun. The mineral wealth of the country is neither extensive nor varied; but iron-mines are worked, and gold is found in the River Emme. Quarries of sandstone, marble, and granite are abundant. The pastures in the Oberland and the Emmenthal are excellent, and cattle and horses of the best description are largely reared. The latter district also produces cheese of excellent quality, which is exported to Germany and Italy. Fruit is extensively cultivated in the central region and in the neighbourhood of the lakes of Brienz and Thun; the vine is principally grown to the north of Lake Bienne. In the forests, which are of considerable importance, the prevailing trees are the fir, the pine, and the beech. The industrial productions of the canton are cotton, woollen and flaxen stuffs, leather, watches, and wooden wares of all kinds. Bern is divided into thirty bailiwicks or prefectures, each with a local administrator. The capital is Bern, and the other chief towns are Bienne or Biel, Thun, Burgdorf or Berthoud, Porrentruy or Pruntruit, and Délémont or Delsberg. The highest legislative authority is the Great Council, the members of which are chosen in proportion to the number of the people; and the executive power is in the hands of a lesser council of nine members, chosen by the Great Council for a space of four years. The educational institutions in the canton comprise a university and two gymnasiums in the capital, and progymnasiums and colleges at Biel, Thun, Burgdorf, Neuenstadt, Porrentruy, and Délémont. There is a deaf and dumb institution at Frienisberg, and a cantonal lunatic asylum at Waldau, about a mile from Bern.



Plan of Bern

BERN, the capital of the above canton, and, since 1848, the permanent seat of the Government and Diet of the Swiss Confederation. It is situated in 46° 47′ N. lat. and 7° 25′ E. long. at an elevation of 1710 feet above the sea, on a sandstone peninsula, formed by the windings of the Aar, which is crossed on the south side of the city by an extensive weir, and further down passes under four bridges connecting the peninsula with the right bank. It is one of the most characteristically Swiss towns; some of the streets are broad and regular, the houses being well built with hewn stone; in others a peculiar effect is produced by the presence of lines of arcades down the sides. Prominent among the public buildings is the Federal Council Hall, or *Bundes-Rathhaus*, a fine structure in the

Florentine style, which was completed in 1857. The upper story is occupied by a picture-gallery of some value. The town-hall dates from 1406, and was restored in 1861. Among the ecclesiastical buildings the first place is held by the cathedral, a richly-decorated Gothic edifice, begun in 1421 and completed in 1573, from the neighbourhood of which a splendid view of the Alps is obtained. Educational institutions are very numerous, comprising a university, founded in 1834, which is attended by 250 students, a gymnasium, and a veterinary school. Attached to the university are a botanical garden and an observatory; and there are, besides, a valuable museum, a public library of 45,000 volumes, especially rich in works relating to Swiss history, and several literary and scientific societies. Among the charitable establishments are two large hospitals (the Inselspital and the Bürgerspital), a foundling hospital, two orphan asylums, and a lunatic asylum. Another asylum was erected in 1854, about 2½ miles from the city. The penitentiary is capable of containing 400 prisoners. Among other buildings of interest are the granary, which, till 1830, used to be stored with corn in case of famine; the clock tower, with its automatic pantomime; the arsenal, with its mediæval treasures; the mint; and the Murtner Gate. The most frequent ornament throughout the city is the figure of the bear, in allusion to the mythical origin of the name of Bern; and the authorities still maintain a bear's den at municipal expense. Although, properly speaking, not a commercial city, Bern carries on some trade in woollen cloth, printed calico, muslin, silk stuffs, straw hats, stockings, and other articles of home manufacture. The climate is severely cold in winter, owing to the elevation of the situation. The population, which is mainly Protestant, was 36,000 in 1870.

Bern was founded, or at least fortified, by Berthold V. of Zahringen, about the end of the 12th or beginning of the 13th century, and gradually became a refuge for those who were oppressed by feudal exactions in the neighbouring countries. In 1218 it was declared a free imperial city by the Emperor Frederick II. At first its constitution was purely democratic; but in 1293 a legislative body of 200 citizens was appointed, which formed the germ of one of the most remarkable oligarchies in modern European history. The extension of territory, gradually effected by the valour of the Bernese, rendered necessary a more elaborate and rigid organization than that which had sufficed while the limits of the city were almost the limits of the state; and the power of the nobility at home was strengthened by every new success against the enemies of the city. The blow that decided the fate of Bern was struck at Laupen on June 21, 1339, when Rudolph von Erlach beat the allied army of the neighbouring states It continued to flourish, and in 1352 joined the Swiss Confederation. A fire destroyed the city in 1405, but it was rebuilt on the same plan. In the 17th century the gradually increasing aristocratic tendency reached its climax. The adoption of new burghers was forbidden, and the burghers proper were carefully distinguished from those who were merely permanent inhabitants of the city; the burghers were divided into those capable of holding office in the state and those destitute of that privilege; and the privileged class itself which, by 1785, numbered only 69 families, was subdivided into a higher and a lower grade. This élite grew more and more exclusive and domineering, and at last became unendurable to their humbler fellow-citizens. In 1748 the discontent made itself evident in a formidable conspiracy, of which the unfortunate Henzi was one of the leaders. The conspiracy was crushed, but the opposition broke out through other channels. At last the French Revolution came to submerge the aristocracy in a general Helvetian republic; and when the flood had passed the ancient landmarks could not be replaced, though a restoration was attempted with at first an appearance of success. The Liberal party has long been the strongest in the canton, which has at last returned almost to democracy; for, in 1870, the *referendum* was introduced, by which it is agreed that all laws, after being discussed by the Great Council, shall first receive the sanction of the people before they come into force.

BERNADOTTE, Jean-Baptiste-Jules, afterwards King Charles XIV. of Sweden and Norway, was the son of a lawyer at Pau in Béarn, and was born January 26, 1764. He was destined by his parents for the law, but chose the profession of arms, and enlisted in 1780 as a private in the royal marines. When the Revolution swept away the arbitrary distinction of classes, and opened up to all alike the path of preferment, the abilities of Bernadotte were speedily acknowledged. In 1792 he was made a colonel, in the following year a general of brigade, and soon after a general of division. In the campaigns of the Rhine and of Italy his military talents found ample scope for display; and his diplomatic abilities had also been tested as ambassador at the court of Vienna. During Bonaparte's absence in Egypt Bernadotte was appointed minister of war. He reorganized the whole army, and prepared the way for the conquest of Holland. Notwithstanding the rivalry that all along existed between him and Napoleon, Bernadotte was made a marshal on the establishment of the empire. He was also nominated to the government of Hanover, and took part in the campaign of 1805 at the head of a force of 20,000 men. He distinguished himself at the battle of Austerlitz, and in 1806 he was created prince of Ponte-Corvo. In 1810 the death of Prince Augustenburg of Sweden having left the throne of that kingdom without an heir, the Swedish States in Council nominated Bernadotte as successor to Charles XIII. of Sweden, a distinction for which he was scarcely less indebted to his nobility of character than to his military talents. During the great campaigns of 1813 and 1814 Bernadotte joined the coalition against Napoleon, and it was his Swedish contingent that mainly decided the battle of Leipsic. It is stated, on good authority, that he had formed the ambitious design of succeeding the emperor on the French throne. As crown prince of Sweden he devoted his whole energies to the welfare of his adopted country. Owing to the infirmities of the king he was intrusted with the entire conduct of the government. On the death of Charles XIII., in February 1818, Bernadotte ascended the throne. For the events of his administration, so conducive to the prosperity of that country, the reader is referred to the article Sweden. He died at Stockholm, March 8, 1844, leaving an only son, Oscar, who succeeded him.

BERNARD, St, one of the most illustrious Christian teachers and representatives of monasticism in the Middle Ages, was born at Fontaines, near Dijon, in Burgundy, in 1091. The son of a knight and vassal of the duke of Burgundy who perished in the first crusade, Bernard may have felt for a time the temptations of a military career, but the influence of a pious mother and his own inclinations towards a life of meditation and study led him to the cloister. While still a youth he is said to have been "marvellously cogitative" ("*mire cogitativus*," St Bern. *Op.*, vol. ii. col. 1063), and the ascendency of his mind and character were soon shown. He joined the small monastery of Citeaux in 1113 when twenty-two years of age, and such were the effects of his own devotion and eloquent enthusiasm in commending a religious life, that he drew after him not only his two younger brothers, but also his two elder ones, Guido and Gerard, both of whom had naturally taken to soldiering, and the elder of whom was married and had children. The effect of his preaching is said to have been that "mothers hid their sons, wives their husbands, companions their friends," lest they should be drawn away by his persuasive earnestness.

The monastery of Citeaux had attracted St Bernard not only on account of its neighbourhood (it was only a few miles distant from Dijon), but by its reputation for austerity. The monks were few and very poor. They were under an Englishman of the name of Stephen Harding, originally from Dorsetshire, whose aim was to restore the Benedictine rule to its original simplicity and give a new impulse to the monastic movement. In Bernard, Harding found a congenial spirit. No amount of self-mortification could exceed his ambition. He strove to overcome his

bodily senses altogether and to live entirely absorbed in religious meditation. Sleep he counted a loss, and compared it to death. Food was only taken to keep him from fainting The most menial offices were his delight, and even then his humility looked around for some lowlier employment Fortunately he loved nature, and found a constant solace in her rocks and woods. "Trust one who has tried it," he writes in one of his epistles, "you will find more in woods than in books; trees and stones will teach you what you can never learn from masters." ("Experto crede: aliquid amplius invenies in silvis quam in libris; ligna et lapides docebunt te quod a magistris audire non possis," *Epist.* 106.)

So ardent a nature soon found a sphere of ambition for itself. The monks of Citeaux, from being a poor and unknown company, began to attract attention after the accession of St Bernard and his friends. The fame of their self-denial was noised abroad, and out of their lowliness and abnegation came as usual distinction and success. The small monastery was unable to contain the inmates that gathered within it, and it began to send forth colonies in various directions. St Bernard had been two years an inmate, and the penetrating eye of the abbot had discovered beneath all his spiritual devotion a genius of rare power, and especially fitted to aid his measures of monastic reform. He was chosen accordingly to head a band of devotees who issued from Citeaux in 1115 in search of a new home. This band, with Bernard at their head, journeyed northwards till they reached a spot in the diocese of Langres -a thick-wooded valley, wild and gloomy, but with a clear stream running through it. Here they settled and laid the foundations of the famous abbey of Clairvaux, with which St Bernard's name remains associated in history. The hardships which the monks endured for a time in their new abode were such as to drive them almost to despair, and their leader fell seriously ill, and was only rescued from what seemed impending death by the kind compulsion of his friend William of Champeaux, the great doctor of the age, who besought and received the direction of Bernard for a year from his superior at Citeaux. Thanks to his considerate friend the abbot of Clairvaux was forced to abandon the cares of his new establishment, and in retirement and a healthful regimen to seek renewed health. The effect was all that could be desired, and in a few years Bernard had not only recovered his strength, but had begun that marvellous career of literary and ecclesiastical activity, of incessant correspondence and preaching, which was to make him in some respects the most influential man of his age.

Gradually the influence of Bernard's character began to extend beyond his monastery. His friendship with William of Champeaux and others gave currency to his opinions, and from his simple retreat came by voice or pen an authority before which many bowed, not only within his own order but within the church at large. This influence was notably shown after the death of Pope Honorius II. in 1130. Two rival popes assumed the purple, each being able to appeal to his election by a section of the cardinals. Christendom was divided betwixt the claims of Anacletus II. and Innocent II. The former was backed by a strong Italian party, and drove his adversary from Rome and even from Italy. Innocent took refuge in France. The king, Louis the Fat, espoused his cause, and having summoned a council of archbishops and bishops, he laid his commands on the holy abbot of Clairvaux to be present also and give the benefit of his advice. With reluctance Bernard obeyed the call, and from the depths of seclusion was at once plunged into the heart of the great contest which was afflicting the Christian world. The king and prelates put the question before him in such a way as to invite his decision and make him arbiter. After careful deliberation he gave his judgment in favour of Innocent, and not only so, but from that time forward threw himself with characteristic fervour and force into the cause for which he had declared. Not only France, but England, Spain, and Germany were won to the side of Innocent, who, banished from Rome, in the words of St Bernard, was "accepted by the world." He travelled from place to place with the powerful abbot by his side, who also received him in his humble cell at Clairvaux. Apparently, however, the meanness of the accommodation and the scantiness of the fare (one small fowl was all that could be got for the Pope's repast), left no wish on the part of Innocent or his retinue to continue their stay at Clairvaux. He found a more dainty reception elsewhere, but nowhere so powerful a friend. Through the persuasions of Bernard the emperor took up arms for Innocent; and Anacletus was driven to shut himself up in the impregnable castle of St Angelo, where his death opened the prospect of a united Christendom. A second anti-pope was elected, but after a few months retired from the field, owing also, it is said, to St Bernard's influence. A great triumph was gained not without a struggle, and the abbot of Clairvaux remained master of the ecclesiastical situation. No name stood higher in the Christian world.

The chief events which fill up his subsequent life attest the greatness of his influence. These were his contest with the famous Abelard, and his preaching of the second crusade.

Peter Abelard was twelve years older than Bernard, and had risen to eminence before Bernard had entered the gates of Citeaux. His first intellectual encounter had been with Bernard's aged friend William of Champeaux, whom he had driven from his scholastic throne at Paris by the superiority of his dialectics. His subsequent career, his ill-fated passion for Heloise, his misfortunes, his intellectual restlessness and audacity, his supposed heresies, had all shed additional renown on his name; and when a council was summoned at Sens in 1140, at which the French king and his nobles and all the prelates of the realm were to be present, Abelard dared his enemies to impugn his opinions. St Bernard had been amongst those most alarmed by Abelard's teaching, and had sought to stir up alike Pope, princes, and bishops to take measures against him. He did not readily, however, take up the gauntlet thrown down by the great hero of the schools. He professed himself a "stripling too unversed in logic to meet the giant practised in every kind of debate." But "all were come prepared for a spectacle," and he was forced into the field. To the amazement of all, when the combatants met and all seemed ready for the intellectual fray, Abelard refused to proceed with his defence. After several passages considered to be heretical had been read from his books he made no reply, but at once appealed to Rome and left the assembly. Probably he saw enough in the character of the meeting to assure him that it formed a very different audience from those which he had been accustomed to sway by his subtilty and eloquence, and had recourse to this expedient to gain time and foil his adversaries. Bernard followed up his assault by a letter of indictment to the Pope against the heretic. The Pope responded by a sentence of condemnation, and Abelard was silenced. Soon after he found refuge at Cluny with the kindly abbot, Peter the Venerable, who brought about something of a reconciliation betwixt him and Bernard. The latter, however, never heartily forgave the heretic. He was too zealous a churchman not to see the danger there is in such a spirit as Abelard's, and the serious consequences to which it might lead..

In all things Bernard was enthusiastically devoted to the church, and it was this enthusiasm which led him at last into the chief error of his career. Bad news reached

France of the progress of the Turkish arms in the East. The capture of Edessa in 1144 sent a thrill of alarm and indignation throughout Christian Europe, and the French king was urged to send forth a new army to reclaim the Holy Land from the triumphant infidels. The Pope was consulted, and encouraged the good work, delegating to St Bernard the office of preaching the new crusade. Weary with growing years and cares the abbot of Clairvaux seemed at first reluctant, but afterwards threw himself with all his accustomed power into the new movement, and by his marvellous eloquence kindled the crusading madness once more throughout France and Germany. Not only the French king, Louis VII., but the German emperor, Conrad III., placed himself at the head of a vast army and set out for the East by way of Constantinople. Detained there too long by the duplicity of the Greeks, and divided in counsel, the Christian armies encountered frightful hardships, and were at length either dispersed or destroyed. Utter ruin and misery followed in the wake of the wildest enthusiasm. Bernard became an object of abuse as the great preacher of a movement which had terminated so disastrously, and wrote in humility an apologetic letter to the Pope, in which the divine judgments are made as usual accountable for human folly. This and other anxieties bore heavily upon even so sanguine a spirit. Disaster abroad and heresy at home left him no peace, while his body was worn to a shadow by his fasting and labours. It was, as he said, "the season of calamities." Still to the last, with failing strength, sleepless, unable to take solid food, with limbs swollen and feeble, his spirit was unconquerable. "Whenever a great necessity called him forth," as his friend and biographer Godfrey says, "his mind conquered all his bodily infirmities, he was endowed with strength, and to the astonishment of all who saw him, he could surpass even robust men in his endurance of fatigue." He continued absorbed in public affairs, and dispensed his care and advice in all directions often about the most trivial as well as the most important affairs. Finally the death of his associates and friends left him without any desire to live. He longed rather "to depart and be with Christ." To his sorrowing monks, whose earnest prayers were supposed to have assisted his partial recovery when near his end, he said, "Why do you thus detain a miserable man? Spare me. Spare me, and let me depart." He expired August 20, 1153, shortly after his disciple Pope Eugenius III.

His character appears in our brief sketch as that of a noble enthusiast, selfish in nothing save in so far as the church had become a part of himself, ardent in his sympathies and friendships, tenacious of purpose, terrible in indignation. He spared no abuse, and denounced what he deemed corruption to the Pope as frankly as to one of his own monks. He is not a thinker nor a man in advance of his age, but much of the best thought and piety of his time are sublimed in him to a sweet mystery and rapture of sentiment which has still power to touch amidst all its rhetorical exaggerations.

His writings are very numerous, consisting of epistles, sermons, and theological treatises. The best edition of his works is that of Father Mabillon, printed at Paris in 1690 in 2 vols. folio, and reprinted more than once—finally in 1854 in 4 vols. 8vo. His life, written by his friend and disciple Godfrey, is also contained in this edition of his works. (J. T.)

BERNARD, James, professor of philosophy and mathematics, and minister of the Walloon church at Leyden, was born at Nions, in Dauphiné, September 1, 1658. Having studied at Geneva, he returned to France in 1679, and was chosen minister of Venterol, in Dauphiné, whence he afterwards removed to the church of Vinsobres. As he continued to preach the Reformed doctrines in opposition to the royal ordinance, he was obliged to leave the country and retired to Holland, where he was well received, and appointed one of the pensionary ministers of Gouda. In July 1686 he commenced his *Histoire Abrégée de l'Europe*, which he continued monthly till December 1688. In 1692 he began his *Lettres Historiques*, containing an account of the most important transactions in Europe; he carried on this work till the end of 1698, after which it was continued by others. When Leclerc discontinued his *Bibliothèque Universelle* in 1691, Bernard wrote the greater part of the twentieth volume and the five following volumes. In 1698 he collected and published *Actes et Négociations de la Paix de Ryswic*, in four volumes 12mo. In 1699 he began a continuation of Bayle's *Nouvelles de la République des Lettres*, which continued till December 1710. In 1705 he was unanimously elected one of the ministers of the Walloon church at Leyden; and about the same time he succeeded M. de Valder in the chair of philosophy and mathematics at Leyden. In 1716 he published a supplement to Moreri's Dictionary, in two volumes folio. The same year he resumed his *Nouvelles de la République des Lettres*, and continued it till his death, on the 27th of April 1718 Besides the works above mentioned, he was the author of two practical treatises, one on late repentance, the other on the excellence of religion.

BERNARD, Simon, French general of engineers, and aide-de-camp to Napoleon, was born at Dôle in 1779. He was educated at the École Polytechnique, and entered the army in the corps of engineers. He rose rapidly, and served for some time as aide-de-camp to Napoleon. Subsequently to the emperor's fall he emigrated to the United States, where he executed a number of extensive military works, consisting of vast canals, numerous forts, and 1400 leagues of frontier fortifications. He returned to France after the Revolution of 1830, and in 1836 was secretary at war to Louis Philippe. He died in 1839.

BERNARDIN, St, of Siena, a celebrated preacher, was born at Massa Carrara in 1380. His family, the Albizeschi, was noble, and his father was chief magistrate of Massa. He lost both parents before his eighth year, and was educated by his aunt, a pious woman. After completing his course of study he passed some years as a voluntary assistant in the hospital of Scala, and in 1404 entered the order of St Francis. His eloquence as a preacher made him celebrated throughout Italy, nor was his fame diminished by his visit to the Holy Land, from which he returned with fresh zeal. Three cities, Siena, Ferrara, and Urbino, successively sought the honour of having him as their bishop, but without avail. In 1438 he was made vicar-general of his order in Italy. He died on the 20th May 1444, at Aquila in Abruzzo. His canonization took place in 1450 by the order of Nicholas V. A collection of his works was published in 1571 by Rudolfi, bishop of Sinigaglia.

BERNAY, the chief town of an arrondissement in the department of Eure, in France, on the left bank of the Charentonne, 26 miles W.N.W. of Evreux. It is beautifully situated in the midst of green wooded hills, and still justifies Madame de Stael's description—"Bernay is a basket of flowers." Of great antiquity, it still possesses numerous quaint wooden houses and several ancient ecclesiastical buildings of considerable interest. The abbey church is now used as a market, and the abbey, which was originally founded by Judith of Britanny about 1017, and underwent a restoration in the 17th century, serves for municipal and legal purposes. The glass-work in the church of Nôtre Dame de la Couture is of great antiquarian interest. Among the industrial establishments of the place are cotton, woollen, and ribband factories;

and the trade is chiefly in horses, grain, and flax. The town, which was formerly fortified, was besieged by Duguesclin in 1378; it was taken by the English in 1418 and again in 1421, and by Admiral de Coligny in 1563. The fortress was razed in 1589. Population in 1872, 5806.

BERNBURG, a city of Anhalt in Germany, and formerly the capital of the now incorporated duchy of Anhalt-Bernburg. It consists of three parts, the *Altstadt* or old town, the *Bergstadt* or hill-town, and the *Neustadt* or new town,—the Bergstadt on the right and the other two on the left of the River Saale, which is crossed by a rather massive stone bridge. It is a well-built city, the principal public buildings being the Government house, the church of St Mary, the Gymnasium, and the house of correction. The castle, formerly the ducal residence, is in the Bergstadt, defended by moats, and surrounded by beautiful gardens. The industries of the town include the manufacture of snuff, paper, starch, and pottery; and a considerable traffic is carried on, especially in grain, both by river and by railway. Bernburg is of great antiquity. The Bergstadt was fortified by Otto III. in the 10th century, and the new town was founded in the 13th. For a long period the different parts were under separate magistracies, the new town uniting with the old in 1560, and the Bergstadt with both in 1824. Prince Frederick Albert removed the ducal residence to Ballenstedt in 1765. Population in 1872, inclusive of the domain and the suburb of Waldau, 15,709.

BERNE. See Bern.

BERNERS, Juliana, prioress of Sopewell nunnery, near St Albans, was the daughter of Sir James Berners, who was beheaded in the reign of Richard II. She was celebrated for her beauty, her spirit, and her passion for field sports. To her is attributed the *Treatyse perteynynge to Hawkynge, Huntynge, and Fysshynge with an Angle; also a right noble Treatyse on the Lygnage of Cot Armours, endynge with a Treatyse which specyfyeth of Blasynge of Armys*, printed in folio by Wynkyn de Worde in 1496. The first and rarest edition, printed at St Albans in 1486, does not contain the treatise on fishing. Haslewood, who published an edition of the work (in fac-simile of that of Wynkyn de Worde) in 1811, folio, London, has examined with the greatest care the author's claims to figure as the earliest female writer in the English language. His preliminary dissertations contain all the scanty information that is to be had concerning her.

BERNI, Francesco, Italian poet, was born about 1490 at Lamporecchio, in Bibbiena, a district lying along the Upper Arno. His family was of good descent, but excessively poor. At an early age he was sent to Florence, where he remained till his 19th year. He then set out for Rome, trusting to obtain some assistance from his uncle, the Cardinal Bibbiena. The cardinal, however, did nothing for him, and he was obliged to accept a situation as clerk or secretary to Ghiberti, datary to Clement VII. The duties of his office, for which Berni was in every way unfit, were exceedingly irksome to the poet, who, however, made himself celebrated at Rome as the most witty and inventive of a certain club of literary men, who devoted themselves to light and sparkling effusions. So strong was the admiration for Berni's verses, that mocking or burlesque poems have since been called *poesie bernesca*. About the year 1530 he was relieved from his servitude by obtaining a canonry in the cathedral of Florence. In that city he died in 1536, according to tradition poisoned by Duke Alessandro de' Medici, for having refused to poison the duke's cousin, Ippolito de' Medici; but considerable obscurity rests over this story. Berni stands at the head of Italian comic or burlesque poets. For lightness, sparkling wit, variety of form, and fluent diction, his verses are unsurpassed. Perhaps, however, he owes his greatest fame to the recasting (*Rifacimento*) of Boiardo's *Orlando Innamorato*. The enormous success of Ariosto's *Orlando Furioso* had directed fresh attention to the older poem, from which it took its characters, and of which it is the continuation. But Boiardo's work, though good in plan, could never have achieved wide popularity on account of the extreme ruggedness of its style. Berni undertook the revision of the whole poem, avowedly altering no sentiment, removing or adding no incident, but simply giving to each line and stanza due gracefulness and polish. His task he completed with marvellous success; scarcely a line remains as it was, and the general opinion has pronounced decisively in favour of the revision over the original. To each canto he prefixed a few stanzas of reflective verse in the manner of Ariosto, and in one of these introductions he gives us the only certain information we have concerning his own life. It should be noticed that Berni appears to have been favourably disposed towards the Reformation principles at that time introduced into Italy, and this may explain the bitterness of some remarks of his upon the church. The first edition of the *Rifacimento* was printed posthumously in 1541, and it has been supposed that a few passages either did not receive the author's final revision, or have been retouched by another hand. The *Opere Burlesche* have been published separately. A partial translation of Berni's *Orlando* was published by W. S. Rose, 1823. (See for full information Panizzi's Boiardo, 1830–31.)

BERNINI, Giovanni Lorenzo, an Italian artist, born at Naples in 1598, was more celebrated as an architect and a sculptor than as a painter. At a very early age his great skill in modelling introduced him to court favour at Rome, and he was specially patronized by Maffeo Barberini, afterwards Pope Urban VIII., whose palace he designed. None of his sculptured groups at all come up to the promised excellence of his first effort, the Apollo and Daphne, nor are any of his paintings of particular merit. His busts were in so much request that Charles I. of England, being unable to have a personal interview with Bernini, sent him three portraits by Vandyck, from which the artist was enabled to complete his model. His architectural designs, including the great colonnade of St Peter's, brought him perhaps his greatest celebrity. Louis XIV., when he contemplated the restoration of the Louvre, sent for Bernini, but did not adopt his designs. The artist's progress through France was a triumphal procession, and he was most liberally rewarded by the great monarch. He died at Rome in 1680, leaving a fortune of over £100,000. Few artists have had so wide renown in their own day; time has enabled us to judge more accurately of his merits.

BERNOULLI, or Bernouilli, a name illustrious in the annals of science, belonging to a family of respectability, originally of Antwerp. Driven from their country during the oppressive government of Spain for their attachment to the Reformed religion, the family sought first an asylum at Frankfort (1583), and afterwards at Basel, where they ultimately obtained the highest distinctions. In the course of a century eight of its members successfully cultivated various branches of mathematics, and contributed powerfully to the advance of science. The most celebrated of the family were James, John, and Daniel; but, for the sake of perspicuity they may be considered as nearly as possible in the order of family succession.

I. James Bernoulli was born at Basel on the 27th December 1654. He was educated at the public school of Basel, and also received private instruction from the learned Hoffmann, then professor of Greek. At the conclusion of his philosophical studies at the university, some

geometrical figures, which fell in his way, excited in him a passion for mathematical pursuits, and in spite of the opposition of his father, who wished him to be a clergyman, he applied himself in secret to his favourite science. In 1676 he visited Geneva on his way to France, and subsequently travelled to England and Holland. While at Geneva he taught a blind girl several branches of science, and also how to write; and this led him to publish *A Method of Teaching Mathematics to the Blind.* At Bordeaux his *Universal Tables on Dialling* were constructed; and in London he was admitted to the meetings of Boyle, Hooke, Stillingfleet, and other learned and scientific men.

On his final return to Basel in 1682, he devoted himself to physical and mathematical investigations, and opened a public seminary for experimental physics. In the same year he published his essay on comets, *Conamen Novi Systematis Cometarum,* which was occasioned by the appearance of the comet of 1680. This essay, and his next publication, entitled *De Gravitate Ætheris,* were deeply tinged with the philosophy of Descartes, but they contain truths not unworthy of the philosophy of the *Principia.*

James Bernoulli cannot be strictly called an independent discoverer; but, from his extensive and successful application of the calculus, he is well deserving of a place by the side of Newton and Leibnitz. As an additional claim to remembrance, he was the first to solve Leibnitz's problem of the isochronous curve, and to determine the catenary, or curve formed by a chain suspended by its two extremities, which he also showed to be the same as the curvature of a sail filled with wind. This led him on to another curve, which, being formed by an elastic plate or rod fixed at one end and bent by a weight applied to the other, he called the elastic curve, and which he showed to be the same as the curvature of an impervious sail filled with a liquid. In his investigations respecting cycloidal lines and various spiral curves, his attention was directed to the loxodromic and logarithmic spirals, in the last of which he took particular interest from its remarkable property of reproducing itself under a great variety of conditions.

In 1696 he proposed the famous problem of isoperimetrical figures, and offered a reward for its solution. This problem engaged the attention of British as well as Continental mathematicians; and its proposal gave rise to a painful quarrel between the brothers. John offered a solution of the problem; his brother pronounced it to be wrong. John then amended his solution, and again offered it, and claimed the reward. James still declared it to be no solution, and soon after published his own. In 1701 he published also the demonstration of his solution, which was accepted by De l'Hôpital and Leibnitz. John, however, held his peace for several years, and then dishonestly published, after the death of James, another incorrect solution; and not until 1718 did he admit that he had been in error. Even then he set forth as his own his brother's solution purposely disguised.

In 1687 the mathematical chair of the University of Basel was conferred upon James; and in the discharge of its duties he was so successful as to attract students from other countries. Some of his pupils became afterwards professors in the universities of Germany. He was once made rector of his university, and had other distinctions bestowed on him. He and his brother John were the first two foreign associates of the Academy of Sciences at Paris; and, at the request of Leibnitz, they were both received as members of the Academy of Berlin. In 1684 he had been offered a professorship at Heidelberg; but his marriage with a lady of his native city led him to decline the invitation. Intense application brought on infirmities and a slow fever, of which he died on the 16th of August 1705, with the resignation of a Christian and the firmness of a philosopher. Like another Archimedes, he requested that, as a monument of his labours and an emblem of his hope of a resurrection, the logarithmic spiral should be engraven on his tombstone, with these words, *Eadem mutata resurgo.*

James Bernoulli wrote elegant verses in Latin, German, and French; but although these were held in high estimation in his own time, it is on his mathematical works that his fame now rests. These are—(1.) *Jacobi Bernoulli Basiliensis Opera,* Genevæ, 1744, 2 tom. 4to; (2.) *Ars Conjectandi, opus posthumum: accedunt tractatus de Seriebus Infinitis, et epistola (Gallice scripta) de Ludo Pilæ Reticularis,* Basiliæ, 1713, 1 tom. 4to.

II. JOHN BERNOULLI, brother of the preceding, was born at Basel on the 7th August 1667. His education was begun at six years of age; and after finishing his literary studies he was sent to Neufchâtel to learn commerce and acquire the French language. But at the end of a year he renounced the pursuits of commerce, returned to the University of Basel, and was admitted to the degree of bachelor in philosophy, and a year later, at the age of 18, to that of master of arts. In his studies he was aided by his elder brother James. Chemistry, as well as mathematics, seems to have been the object of his early attention; and in the year 1690 he published a dissertation on effervescence and fermentation. The same year he went to Geneva, where he gave instruction in the differential calculus to Fatio de Duiller, and afterwards proceeded to Paris, where he enjoyed the society of Malebranche, Cassini, De Lahire, and Varignon. With the Marquis de l'Hôpital he spent four months at his country house in the study of the higher geometry and the resources of the new calculus. His independent discoveries in mathematics are numerous and important. Among these were the exponential calculus, and the curve called by him the *linea brachistochrona,* or line of swiftest descent, which he was the first to determine, pointing out at the same time the beautiful relation which this curve bears to the path described by a ray or particle of light passing through strata of variable density, such as our atmosphere. On his return to his native city he studied medicine, and in 1694 took the degree of M.D. At this period he married into one of the oldest families in Basel; and although he had declined a professorship in Germany, he now accepted an invitation to the chair of mathematics at Groningen (*Commercium Philosophicum,* epist. xi. and xii.) There, in addition to the learned lectures by which he endeavoured to revive mathematical science in the university, he gave a public course of experimental physics. During a residence of ten years in Groningen, his controversies were almost as numerous as his discoveries. His dissertation on an electrical appearance of the barometer first observed by Picard, and discussed by John Bernoulli under the name of mercurial phosphorus, or mercury shining in vacuo (*Diss. Physica de Mercurio lucente in vacuo*), procured him the notice of royalty, and engaged him in controversy. Through Leibnitz he received from the king of Prussia a gold medal for his supposed discoveries, but Hartsoeker and some of the French academicians disputed the fact. The family quarrel about the problem of isoperimetrical figures above mentioned began about this time. In his dispute with his brother, in his controversies with the English and Scotch mathematicians, and in his harsh and jealous bearing to his son Daniel, he showed a temper mean, unfair, and violent. He had declined, during his residence at Groningen, an invitation to Utrecht, but accepted in 1705 the mathematical chair in the university of his native city, vacant by the death of his brother James; and here he remained till his death. His inaugural discourse was on the "new analysis," which he so successfully applied in investigating

various problems both in pure and mixed mathematics. At the request of the magistracy of Basel he applied himself to correct the relaxed discipline of the university.

He was several times a successful competitor for the prizes given by the Academy of Sciences of Paris; and the subjects of his essays were, the laws of motion (*Discours sur les Lois de la Communication du Mouvement*, 1727), the elliptical orbits of the planets, and the inclinations of the planetary orbits (*Essai d'une Nouvelle Physique Céleste*, 1735). In the last case his son Daniel divided the prize with him. Some years after his return to Basel he published an essay, entitled *Nouvelle Théorie de la Manœuvre des Vaisseaux*. It is, however, his works in pure mathematics that are the permanent monuments of his fame. D'Alembert acknowledges with gratitude, that "whatever he knew of mathematics he owed to the works of John Bernoulli." He was a member of almost every learned society in Europe, and one of the first mathematicians of a mathematical age. He was as keen in his resentments as he was ardent in his friendships; fondly attached to his family, he yet disliked a deserving son; he gave full praise to Leibnitz and Euler, yet was blind to the excellence of Newton. Such was the vigour of his constitution that he continued to pursue his usual mathematical studies till the age of eighty. He was then attacked by a complaint at first apparently trifling; but his strength daily and rapidly declined till the 1st of January 1748, when he died peacefully in his sleep.

His writings were collected under his own eye by Cramer, professor of mathematics at Geneva, and published under the title of *Johannis Bernoulli Operi Omnia*, Lausan. et Genev. 4 tom. 4to. His interesting correspondence with Leibnitz appeared under the title of *Gul. Leibnitii et Johannis Bernoulli Commercium Philosophicum et Mathematicum*, Lausan. et Genev. 1745, 2 tom. 4to.

III. Nicholas Bernoulli, the eldest of the three sons of John Bernoulli, was born in 1695. His early indications of genius were carefully cherished. At the age of eight he could speak German, Dutch, French, and Latin. When his father returned to Basel he went to the university of that city, where, at the age of sixteen, he took the degree of doctor in philosophy, and four years later the highest degree in law. Meanwhile the study of mathematics was not neglected, as appears not only from his giving instructions in geometry to his younger brother Daniel, but from his writings on the differential, integral, and exponential calculus, and from his father considering him, at the age of twenty-one, worthy of receiving the torch of science from his own hands. ("Lampada nunc tradam filio meo natu maximo, juveni xxi. annorum, ingenio mathematico aliisque dotibus satis instructo," *Com. Phil.* ep. 223). With his father's permission he visited Italy and France, and during his travels formed friendship with Varignon and with Riccati, one of the first mathematicians of Italy. The invitation of a Venetian nobleman induced him again to visit Italy, where he resided two years, till his return to be a candidate for the chair of jurisprudence at Basel. He was unsuccessful, but was soon afterwards appointed to a similar office in the University of Bern. Here he resided three years, his happiness only marred by regret on account of his separation from his brother Daniel, with whom he was united in sentiment and pursuits. Both were appointed at the same time professors of mathematics in the Academy of St Petersburg; but this office Nicholas enjoyed for little more than eight months. At the end of July 1726 he was cut off in the prime of life by a lingering fever. Sensible of the loss which the nation had sustained by his death, the Empress Catherine ordered him a funeral at the public expense. Some of his papers are published in his father's works, and others in the *Acta Eruditorum* and the *Comment. Acad. Petropol.*

IV. Daniel Bernoulli, the second son of John Bernoulli, was born 9th February 1700, at Groningen. He studied medicine and became a physician, but his attention was early directed also to geometrical studies. The severity of his father's manner was ill calculated to encourage the first efforts of one so sensitive; but fortunately, at the age of eleven, he became the pupil of his brother Nicholas. He afterwards studied in Italy under Michelotti and Morgagni. After his return, though only twenty-four years of age, he was invited to become president of an academy then projected at Genoa; but, declining this honour, he was, in the following year, appointed professor of mathematics at St Petersburg. In consequence of the state of his health, however, he returned to Basel in 1733, where he was appointed professor of anatomy and botany, and afterwards of experimental and speculative philosophy. In the labours of this office he spent the remaining years of his life. He had previously published some medical and botanical dissertations, besides his *Exercitationes quædam Mathematicæ*, containing a solution of the differential equation proposed by Riccati and now known by his name. In 1738 appeared his *Hydrodynamica*, in which the equilibrium, the pressure, the reaction, and varied velocities of fluids are considered both theoretically and practically. One of these problems, illustrated by experiment, deals with an ingenious mode of propelling vessels by the reaction of water ejected from the stern. Some of his experiments on this subject were performed before Maupertuis and Clairaut, whom the fame of the Bernoullis had attracted to Basel. With a success equalled only by Euler, Daniel Bernoulli gained or shared no less than ten prizes of the Academy of Sciences of Paris. The first, for a memoir on the construction of a clepsydra for measuring time exactly at sea, he gained at the age of twenty-four; the second, for one on the physical cause of the inclination of the planetary orbits, he divided with his father; and the third, for a communication on the tides, he shared with Euler, Maclaurin, and another competitor. The problem of vibrating cords which had been some time before resolved by Taylor and D'Alembert, became the subject of a long discussion conducted in a generous spirit between Bernoulli and his friend Euler. In one of his early investigations he gave an ingenious though indirect demonstration of the problem of the parallelogram of forces. His labours in the decline of life were chiefly directed to the doctrine of probabilities in reference to practical purposes, and in particular to economical subjects, as, for example, to inoculation, and to the duration of married life in the two sexes, as well as to the relative proportion of male and female births. He retained his usual vigour of understanding till near the age of eighty, when his nephew James relieved him of his public duties. He was afflicted with asthma, and his retirement was relieved only by the society of a few chosen friends. In the spring of 1782, after some days' illness, he died, like his father, in the repose of sleep. Excluded by his professional character from the councils of the republic, he nevertheless received all the deference and honour due to a first magistrate. He was wont to mention the following as the two incidents in his life which had afforded him the greatest pleasure,—that a stranger, whom he had met as a travelling companion in his youth, made to his declaration "I am Daniel Bernoulli" the incredulous and mocking reply, "And I am Isaac Newton;" and that, while entertaining König and other guests, he solved without rising from table a problem which that mathematician had submitted as difficult and lengthy.

Like his father, he was a member of almost every learned society of Europe, and he succeeded him as foreign associate of the Academy of Paris. Several of his investigations are contained in the earlier volumes of the St

Petersburg Memoirs; and his separately published works are—(1.) *Dissertatio Inaugur. Phys. Med. de Respiratione*, Basil., 1721, 4to; (2.) *Positiones Anatomico-Botanicæ*, Basil., 1721, 4to; (3.) *Exercitationes quædam Mathematicæ*, Venetiis, 1724, 4to; (4.) *Hydrodynamica*, Argentorati, 1738, 4to.

V. JOHN BERNOULLI, the youngest of the three sons of John Bernoulli, was born at Basel on the 18th May 1710. He studied law and mathematics, and, after travelling in France, was for five years professor of eloquence in the university of his native city. On the death of his father he succeeded him as professor of mathematics. He was thrice a successful competitor for the prizes of the Academy of Sciences of Paris. His prize subjects were, the capstan, the propagation of light, and the magnet. He enjoyed the friendship of Maupertuis, who died under his roof while on his way to Berlin. He himself died in 1790. His two sons, John and James, are the last noted mathematicians of the family.

VI. NICHOLAS BERNOULLI, cousin of the three preceding, and son of Nicholas Bernoulli, one of the senators of Basel, was born in that city on the 10th October 1687. He visited England, where he was kindly received by Newton and Halley (*Com. Phil.* ep. 199), held for a time the mathematical chair at Padua, which Galileo had once filled, and was successively professor of logic and of law at Basel, where he died on the 29th of November 1759. He was editor of the *Ars Conjectandi* of his uncle James. His own works are contained in the *Acta Eruditorum*, the *Giornale de' Letterati d'Italia*, and the *Commercium Philosophicum*.

VII. JOHN BERNOULLI, grandson of the first John Bernoulli, and son of the second of that name, was born at Basel on the 4th December 1744. He studied at Basel and at Neufchâtel, and when thirteen years of age took the degree of doctor in philosophy. At nineteen he was appointed astronomer royal of Berlin. Some years after, he visited Germany, France, and England, and subsequently Italy, Russia, and Poland. On his return to Berlin he was appointed director of the mathematical department of the academy. Here he died on the 10th July 1807. His writings consist of travels and astronomical, geographical, and mathematical works. In 1774 he published a French translation of Euler's *Elements of Algebra*. He contributed several papers to the Academy of Berlin.

VIII. JAMES BERNOULLI, younger brother of the preceding, and the second of this name, was born at Basel on the 17th October 1759. Having finished his literary studies, he was, according to custom, sent to Neufchâtel to learn French. On his return he studied law and took a degree. This study, however, did not check his hereditary taste for geometry. The early lessons which he had received from his father were continued by his uncle Daniel, and such was his progress in the exact sciences that at the age of twenty-one he was called to undertake the duties of the chair of experimental physics, which his uncle's advanced years rendered him unable to discharge. He afterwards accepted the situation of secretary to Count de Brenner, which afforded him an opportunity of seeing Germany and Italy. In Italy he formed a friendship with Lorgna, professor of mathematics at Verona, and one of the founders of the Italian society for the encouragement of the sciences. He was also made corresponding member of the Royal Society of Turin; and, while residing at Venice, he was, through the friendly representation of Fuss, admitted into the Academy of St Petersburg. In 1788 he was named one of its mathematical professors. In the following year he married a daughter of Albert Euler, son of the illustrious Euler. This marriage was soon tragically dissolved by the death of the husband, who was drowned while bathing in the Neva in July 1789. Several of his papers are contained in the first six volumes of *Nova Acta Acad. Scien. Imper. Petropol.*, in the *Acta Helvetica*, in the *Memoirs of the Academies of Berlin and Turin*, and in his brother John's publications. He also published separately some juridical and physical theses, and a German translation of *Mémoires du Philosophe de Merian.*

BEROSUS was a Chaldean priest who lived in the time of Alexander the Great and his immediate successors. He translated the history of his native country, Babylonia, into the Greek language, and dedicated the work to one of the Greek kings of Syria named Antiochus. His work is principally known through the fragments of Polyhistor and Apollodorus, two writers in the 1st century before the Christian era, who are quoted by Eusebius and Syncellus.

The work of Berosus professed to commence with the creation of the universe, and the history was carried down to his own time. A few quotations at second or third hand, and the bare outlines of his system of chronology, are all that has been transmitted to us through the copyists of Berosus; but the close connection throughout between his story and the Bible, and the knowledge that he drew his information from the records of Babylonia, have always invested these fragments with great importance,—an importance which has been increased of late, since the discovery of several cuneiform inscriptions confirming different parts of his history.

The history of Berosus first described the chaos before the creation, presided over by the female Thalatth or Omoroca (the chaotic sea), called Tiamat and Tisallat in the inscriptions; she was destroyed by Belus, and then the gods created the heavens and the earth. After this he gave the chronology of the Babylonian kingdom as follows:—

	Years.
10 kings before the flood..	432,000.
86 kings after the flood..	34,080 or 33,091.
8 Median kings..	224, or 234, or 190.
11 other monarchs..	(number lost, in margin 48.)
49 Chaldean kings..	458.
9 Arabian kings..	245.
45 other kings..	526.

After these reigned in Chaldea, Pul.

The later part of the scheme of Berosus is lost, but detached extracts are quoted by some ancient historians.

In comparing the notices of Berosus with the Babylonian and Assyrian inscriptions, considerable difficulty is met with on account of the deficient information on both sides. The absence of chronological landmarks in the inscriptions, and the doubts as to the length of the third and fourth periods of Berosus, are serious difficulties in the way of the chronology, but in the absence of more satisfactory information the list of Berosus must be taken as the framework of Babylonian chronology.

The first period of Berosus, reaching from the creation to the flood, is said to have included 10 reigns and 432,000 years. The last two of these names are the only ones found with any certainty in the cuneiform inscriptions,—these are Ubara-tutu and Adra-hasis, the Otiartes and Xisuthrus of Berosus. The deluge, which closed this period, is described in Berosus, and in the cuneiform inscriptions of the Izdubar legends.

The next period given by Berosus includes 86 kings, and a period of 34,080 or 33,091 years,—the number is uncertain, and certainly unhistorical. It is probable that the later sovereigns of this period were historical, and some of the names which are preserved are ordinary Babylonian compounds. Three names in a fragment of Baby-

lonian chronology appear to belong to this period,—these are Ilu-kassat, Mulagununna, Abilkisu, who are given as successive sovereigns; and there is another probable king of the period, Izdubar, who most likely represents the Biblical Nimrod. During this period the language and people of Babylonia are supposed to have been Turanian, and in round numbers it may be said to end about 2400 B.C.

About 2400 B.C., according to Berosus, Babylonia was overrun by a conquering tribe called by him "Medes." He has preserved in connection with this event the name of Zoroaster, and has given the dynasty 8 kings, the length of the period being placed variously at 234, 224, and 190 years. Where our authorities differ so much we can only make shift with a round number, and say the period was probably about 200 years, from 2400 to 2200 B.C. There is one name in the inscriptions supposed to belong to this period,—that of Kudur-nanhundi, king of Elam, who conquered Babylonia about 2280 B.C. Nothing is known as to the race here called Medes by Berosus, but it is conjectured that they were Elamites.

The next period of Berosus included 11 kings, the duration of the dynasty not being preserved. In the margin we have the number 48 years, but nothing is known of the origin of this number, and it appears too small for 11 kings. Perhaps we may provisionally allow about 200 years for this dynasty, 2200 to 2000 B.C. Nothing is known of the race or names of the monarchs.

About 2000 B.C. commenced a period including, according to Berosus, 49 kings and 458 years. The kings are called Chaldean, and appear to correspond with a famous line of sovereigns reigning at the cities of Ur, Karrak, and Larsa, commencing with the reign of Urukh, king of Ur. The centre of Babylonian power in their time lay in the south of the country, and many of the well-known temples and other buildings in this region were raised during their dominion. One of the monarchs in this period bore the name of Sargon; he was very celebrated, and of him a story is related similar to that of the infancy of Moses. He is said to have been concealed by his mother in an ark and floated on the River Euphrates. This great period ended with the defeat of Rim-agu, king of Larsa, by Hammurabi, who established a new dynasty, and made Babylon the capital about 1550 B.C.

The dynasty founded by Hammurabi appears to be the Arabian line of Berosus, which lasted under 9 kings for 245 years. Many of the kings of this period are known from the inscriptions. They first had extensive relations with the Assyrians, and about 1300 B.C. Tugulti-ninip, king of Assyria, conquered Babylon, and expelled the last Arab monarch. From this time commenced the direct influence of Assyria in Babylonia, and the period of this dynasty is counted by Berosus as 526 years. It probably ended with the time of Pul, a great king and conqueror, about whose personality and date there is much difference of opinion.

The next epoch in Babylonian history is that of Nabonassar, whose era commenced 747 B.C. From his time the history of Babylonia presents a constant series of conquests by the Assyrians, and revolts against them by the Babylonians, down to the time of Nabopolassar, who, after quelling a revolt in Babylonia, was made ruler of the country by the king of Assyria, and afterwards revolting against his master took Nineveh in concert with the Medes.

Nebuchadnezzar, son of Nabopolassar, who ascended the throne of Babylon 605 B.C., was one of the most celebrated kings in history, and is mentioned at length by Berosus, who then notices the revolutions at Babylon until the taking of the city by Cyrus 539 B.C.

The history of Berosus continued down to the conquest of Alexander the Great, and the reign of his patron Antiochus.

The writings and notices of Berosus were collected and published in Germany by Richter in 1825, and in England by Cory, in his *Ancient Fragments*. Later and excellent extracts and notices have been given by Canon Rawlinson and M. Lenormant, while the chronology of Berosus has exercised the ingenuity of Brandis, Oppert, Lenormant, Rawlinson, Hincks, and many other scholars. There is however, no probability that any published system has correctly restored the dates of Berosus; the materials are at present insufficient for such a work. (G. S.)

BERRI, Charles Ferdinand Duc de, younger son of Charles X. of France, was born at Versailles on the 24th Jan. 1778. With his father, then Comte d'Artois, he had to leave France, and for several years served in the army of Condé. He afterwards joined the Russian army, and in 1801 took up his residence in England, where he remained for thirteen years. During that time he married an English lady, by whom he had two children. The marriage was cancelled for political reasons in 1814, when the duke set out for France. His frank, open manners gained him some favour with his fickle countrymen, which was increased by his marriage in 1816 with the Princess Caroline Ferdinande Louise of Naples. On the 13th of February 1820 he was mortally wounded, when leaving the opera-house with his wife, by a man named Louvel. Seven months after his death the duchess gave birth to a son, who received the title of duke of Bordeaux. She was compelled to follow Charles X. in his retirement from France after July 1830, but it was with the resolution of returning speedily and making an attempt to secure the throne for her son. In April 1832 she landed near Marseilles, but receiving no support, was compelled to make her way towards the ever-loyal districts of La Vendée and Bretagne. Her followers, however, were defeated, and after much suffering, she was betrayed to the Government and imprisoned in the castle of Blaye. Here she gave birth to a son, the fruit of a secret marriage contracted with an Italian nobleman, son of the Marchese Lucchesi Palli. The announcement of this marriage at once deprived the duchess of the sympathies of her supporters. She was no longer an object of fear to the French Government, who released her in June 1833. She set sail for Sicily, and from that time till her death in April 1870 lived a retired life with her husband and his relatives.

BERRYER, Pierre Antoine, a French advocate and parliamentary orator, was born at Paris, January 4, 1790, in the midst of the agitating events of the first year of the great Revolution. Berryer's father was an eminent advocate and parliamentary counsellor. The son was educated at the Collége de Juilly, on leaving which he adopted, in deference to his father's wishes, the profession of the law; but his own leaning at that time was to the church. After completing the usual course of professional studies, he was admitted advocate in 1811, and in the same year he married. In the great conflict of the period between Napoleon I. and the Bourbons, Berryer, like his father, was an ardent Legitimist; and in the spring of 1815, at the opening of the campaign of the Hundred Days, he followed Louis XVIII. to Ghent as a volunteer. After the second Restoration he distinguished himself as a courageous advocate of moderation in the treatment of the military adherents of the emperor. He was engaged, in conjunction with his father and Dupin, in the unsuccessful defence of Marshal Ney before the Chamber of Peers; and he undertook alone the defence of General Cambronne and General Debelle, procuring the acquittal of the former and the pardon of the latter. Proceedings were soon after com-

menced against him for some assertions in one of his speeches, but he escaped with nothing more severe than a censure by the Council of Advocates. By this time he had a very large business as advocate, and was engaged on behalf of journalists in many press prosecutions. He stood forward with a noble resolution to maintain the freedom of the press, and severely censured the rigorous measures of the police department. In 1830, not long before the fall of Charles X., Berryer was elected a member of the Chamber of Deputies. He appeared there as the champion of the king, and encouraged him in his tyrannical course. After the Revolution of July, when the Legitimists withdrew in a body, Berryer alone retained his seat as deputy; and though avowedly the friend of the deposed king, he took an independent course, not making himself an unscrupulous partizan, but guided in his advocacy or his opposition by reason and prudence. He was one of the influential men who resisted, but unsuccessfully, the abolition of the hereditary peerage. He advocated trial by jury in press prosecutions, the extension of municipal franchises, and other liberal Measures. In May 1832 he hastened from Paris to see the duchess of Berri on her landing in the south of France for the purpose of organizing an insurrection in favour of her son, the duke of Bordeaux, since known as the count of Chambord. Berryer attempted to turn her from her purpose; and failing in this he set out for Switzerland. He was, however, arrested, imprisoned, and brought to trial as one of the insurgents. He was immediately acquitted. In the following year he pleaded for the liberation of the countess; made a memorable speech in defence of Chateaubriand, who was prosecuted for his violent attacks on the Government of Louis Philippe; and undertook the defence of several Legitimist journalists. In 1834 he defended two deputies in a Government prosecution for libel, and the same year opposed the passing of a new rigorous law against political and other associations. Among the more noteworthy events of his subsequent career were his defence of Louis Napoleon after the ridiculous affair of Boulogne, in 1840, and a visit to England in December 1843, for the purpose of formally acknowledging the pretender, the duke of Bordeaux, then living in London, as Henry V., and lawful king of France. This proceeding brought on him the censure of M. Guizot, then first minister of Louis Philippe. Berryer was an active member of the National Assembly convoked after the Revolution of February 1848, again visited the pretender, then at Wiesbaden, and still fought in the old cause. This long parliamentary career was closed by a courageous protest against the *coup d'état* of December 2, 1851. After a lapse of twelve years, however, he appeared once more in his forsaken field as a deputy to the Corps Législatif. Meanwhile he had been a diligent promoter of the much talked of fusion of the two branches of the Bourbon family, and had distinguished himself at the bar by great speeches on the trial of Montalembert in 1858, and in the civil proceedings set on foot by M. Patterson against Jerome Bonaparte in 1860. Berryer was elected member of the French Academy in 1854. A visit paid by this famous orator to Lord Brougham in 1865 was made the occasion of a banquet given in his honour by the benchers of the Temple and of Lincoln's Inn. In November 1868 he was removed by his own desire from Paris to his country seat at Augerville, and there he died on the 29th of the same month.

BERTHOLLET, Claude Louis, one of the most distinguished chemists of the French school, was born at Talloire, near Annecy, in Savoy, in 1748. He studied first at Chambery, and subsequently at Turin, where he took his degree as a physician. In 1772 he settled at Paris, and soon became the medical attendant of Philip, duke of Orleans. By the publication of a volume of chemical essays, he gained such reputation that he was admitted in 1781 into the Académie des Sciences. He was appointed Government superintendent of the establishment for the improvement of dyeing; and in 1791 he published his essay *Sur la Teinture*, a work that first systematized and chemically explained the principles of the art. It was translated into English by Dr William Hamilton, 1794. Berthollet early adopted the chemical views of Lavoisier, and took part with him in the formation of a new system of chemical nomenclature. He confirmed and extended the discoveries of Priestley on ammonia, discovered fulminating silver, and greatly extended our knowledge of the dephlogisticated marine acid of Scheele, for which the name of oxymuriatic acid was then proposed, and which is now termed chlorine. It was he who in 1785 first proposed to apply it to bleaching. He discovered the remarkable salt now called chlorate of potash; and we owe to him also an excellent essay on the chemical constitution of soaps. Berthollet's contributions to chemistry are scattered through the pages of the *Journal de Physique*, *Annales de Chimie*, *Mémoires de l'Institut*, and *Mémoires d'Arceuil*. At the commencement of the French Revolution the scarcity of saltpetre for the manufacture of gunpowder was much felt; and Berthollet was placed at the head of a commission for improving the processes for obtaining and purifying this important product within the territory of France. Soon afterwards we find him one of a commission for improving the processes in the smelting of iron, and converting it into steel. In 1792 he was appointed a director of the mint, and in 1794 he became a member of the committee on agriculture and the arts; while he filled the office of teacher of chemistry in the Polytechnic and Normal Schools of Paris, and took an active part in the remodelling of the National Institute in 1795. In the following year Berthollet and Monge were appointed heads of a commission to select in Italy the choicest specimens of ancient and modern art, for the national galleries of Paris. In 1798 Berthollet accompanied General Bonaparte to Egypt. On the overthrow of the Directory he was made a senator and a grand officer of the Legion of Honour. Under the empire he was created a count, and he sat as a peer on the restoration of the Bourbons. His last work was his curious essay on *Chemical Statics* (1803), in which he controverted the views of Bergman. Berthollet was a man of great modesty and unostentatious manners. For some years he lived retired at Arcueil, especially after the misconduct and suicide of his only son. He died at Paris of a painful malady bravely borne, November 6, 1822.

BERTHOUD, Ferdinand, a celebrated Swiss chronometer-maker, was born in Neufchâtel. The date of his birth is variously given as 1725, 1727, and 1729. His father was an architect, and the son was intended for the church; but, showing a taste for mechanics, he was placed under an experienced workman to be instructed in clock and watch making, and was afterwards sent to Paris to improve himself in the knowledge and practice of the art. He settled in Paris in 1745, and applied himself to the making of chronometers, an art which was then in its infancy. He soon attained distinction for the excellence of his workmanship and the accuracy of his chronometers. Fleurieu and Borda, by order of the French Government, made a voyage from La Rochelle to the West Indies and Newfoundland for the purpose of testing them, and they found that they gave the longitude with an error of only a quarter of a degree, after a cruise of six weeks. Satisfactory results were also obtained in the expedition of Verdun, Borda, and Pingré, which was appointed to try these chronometers and those of his only rival, Le Roy. Sully,

an English watchmaker established in Paris, was the first who in that city attempted the construction of chronometers for finding the longitude; and this he did in 1724. In 1736 the chronometers of the English artist Harrison were tried at sea. In France, however, there were no chronometer-makers of note after Sully, till Pierre le Roy and Ferdinand Berthoud, between whom there was some discussion about the priority of their discoveries and improvements. Ferdinand Berthoud's chronometers were long the most esteemed of any in France. Louis Berthoud, his nephew and successor, introduced some improvements, and made chronometers of a smaller size and therefore more portable. Berthoud was a member of the French Institute, a fellow of the Royal Society of London, and a member of the Legion of Honour. He was regular in his habits, and retained the use of his faculties to the last. He died of hydrothorax, at his country house, in the valley of Montmorency, in 1807, aged about eighty. The principal of his published works are *Essais sur l'Horlogerie*, 2nd edit., 1786, 2 vols. 4to; two Tracts on Chronometers, 1773; *De la Mésure du Temps*, 1787, 4to; *Les Longitudes par la Mesure du Temps*, 1775, 4to; a Tract on Chronometers, 1782, 4to; *Histoire de la Mésure du Temps par les Horloges*, 1802, 2 vols. 4to; *L'Art de conduire et de régler les Pendules et les Montres*, 1760, 12mo. The tract last named, containing directions suited to general readers for regulating clocks and watches, passed through several editions.

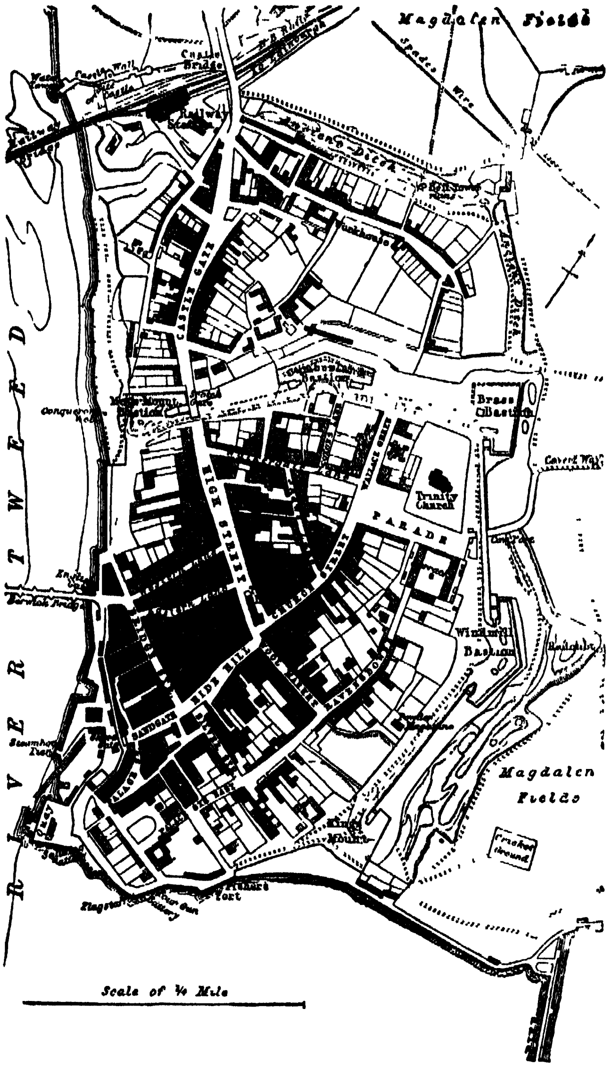
BERTINORO (identified, on conjecture, with the ancient *Forum Druentinorum*), a city of Italy, in the province of Emilia and district of Forli, the seat of the bishop of the united dioceses of Forlimpopoli and Bertinoro. It stands on a hill, below which the River Ronco flows, and is celebrated for the excellence of its wine. Population, 6540. Long. 12° 2′ 30″ E., lat. 44° 8′ 34″ N.

BERWICK, JAMES FITZJAMES, DUKE OF, marshal and peer of France, was a natural son of James, duke of York, afterwards James II. of England, by Arabella Churchill, sister of the great Duke of Marlborough. He was born at Moulins, August 21, 1670. He received his education in France, studying successively at Juilly, at the College of Plessis, and at the College of Flèche. At the age of fifteen, his father having succeeded to the throne, he was sent to learn the business of a soldier under the famous general of the empire, Charles of Lorraine. He served his first campaigns in Hungary, and was present at the siege of Buda and the battle of Mohacz. In 1687 he returned to England, was made a Knight of the Garter, and created duke of Berwick. After the Revolution he served under James II. in the campaign in Ireland, was in one engagement severely wounded, and was present at the battle of the Boyne. For a short time he was left in Ireland as commander-in-chief, but his youth and inexperience unfitted him for the post, and he was a mere puppet in stronger hands. In 1692 he was recalled to France, and took service in the French army. He fought under Marshal Luxembourg in Flanders, took part in the battles of Steinkerk and Landen (Neerwinden), and was taken prisoner at the latter. He was, however, immediately exchanged for the duke of Ormond, and afterwards he served under Villeroi. In 1696 the duke of Berwick took a prominent part in a plot for a Jacobite insurrection, but the scheme came to nothing. In 1702 he served under the duke of Burgundy, and in the following year became naturalized as a Frenchman. In 1704 he first took command of the French army in Spain. So highly was he now esteemed for his courage, abilities, and integrity, that all parties were anxious to have him on their side (*Eloge*, by Montesquieu). From Spain he was recalled to take the command against the Camisards in Languedoc, and when on this expedition he is said to have carried out with remorseless rigour the orders which he received from Versailles. About this time he was created marshal of France. He was then sent again to Spain to retrieve the affairs of that kingdom, and to prop up the tottering throne. In April 1707 he won the great victory of Almanza, an Englishman at the head of a French army, over the earl of Galway (comte de Ruvigny), a Frenchman at the head of an English army. The victory established Philip V. on the throne of Spain, although neither he nor his rival, the archduke, was present at the battle. Berwick was made a peer of France and grandee of Spain. In 1708 he became commander-in-chief of the armies of France in Spain, in Flanders, on the Rhine, and on the Moselle. Through the four following years he gained fresh laurels by his masterly defence of Dauphiné, and in 1713 he returned to Spain and took Barcelona. Three years later he was appointed military governor of the province of Guienne. In 1718 he found himself under the necessity of once more entering Spain with an army; and this time he had to fight against Philip V., the king who owed chiefly to his courage and skill the safety of his throne. One of the marshal's sons, known as the duke of Liria, was settled in Spain, and was counselled by his father not to shrink from doing his duty and fighting for his sovereign. Many years of peace followed this campaign, and Marshal Berwick was not again called to serve in the field till 1733. He advised and conducted in 1734 the siege of Philipsburg on the Rhine, and while the siege was going on was killed by a cannon-shot, June 12 of that year. Cool, self-possessed, and cautious as a general, Marshal Berwick was at the same time not wanting in audacity and swiftness of action in a real crisis. He was careful of the lives of his men, and was also a rigid disciplinarian. Lord Bolingbroke pronounced him the best great man that ever existed. Montesquieu said, "In the works of Plutarch I have seen at a distance what great men were; in Marshal Berwick I have seen what they are." He married in 1695 a daughter of the earl of Clanricarde, by whom he had the son already mentioned. He married a second wife in 1699, by whom he had another son, known as Marshal Fitz-James. The *Mémoires* of Marshal Berwick, revised, annotated, and continued by the Abbé Hook, were published by the marshal's grandson in 1778. An untrustworthy compilation bearing the same title had been published about forty years earlier.

BERWICK-UPON-TWEED, a seaport town and municipal and parliamentary borough, at the mouth of the Tweed, in 55° 46′ N. lat. and 1° 59′ W. long., 300 miles N. by W. from London, and 47 E.S.E. from Edinburgh. Berwick proper is built chiefly on the declivity and flat summit of an elevation rising abruptly from the north side of the river. The liberties of the borough, commonly called "Berwick Bounds," containing an area of nearly eight square miles, extend to the N. and W., and form the N.E. extremity of England. The borough also includes (since 1835) the townships of Tweedmouth and Spittal on the south side of the river,—the latter a fishing and watering place on the coast, the former a manufacturing village connected with Berwick by a bridge. The town has a pleasing appearance from the neighbouring heights, especially at full tide,—sea and river, ramparts, bridges and pier, buildings ancient and modern, and the red-tiled roofs of the houses contributing to the view. The principal streets are wide, well built, and well paved, there being a remarkable absence, in so ancient a town, of narrow streets and old houses.

Berwick is one of the few remaining walled towns in the United Kingdom. The present ramparts were built in the reign of Elizabeth. To the north and east they are formed of earth faced with stone: bastions with cavaliers are

placed at intervals, and a ditch, now dry, extends to the river. Fronting the river are four-gun and six-gun batteries defending the entrance to the harbour, and a twenty-two-gun battery commanding the south side. These ramparts, which are perforated by five gateways, are



Plan of Berwick-upon-Tweed.

generally in good repair, but since 1822 have been destitute of guns save for volunteer practice. The circuit is about 1 mile 3 furlongs; that of the older walls was more than 2 miles. The ruins of the latter, built by Edward I., and also surrounded by a ditch, enclose the suburbs of Castlegate, and the Greens,—the fishermen's quarter. The Bell Tower, from which alarms were given, and which is least dilapidated, has been recently secured from further decay. Between the extremity of these old walls and the Tweed are the remains of the old castle, which was allowed to become a ruin after the union of the crowns. There are no traces of the churches, monasteries, or other ancient buildings of the town. The barracks, built in 1719, accommodate nearly 600 men; but they are now occupied only by militia, and the governor's house has become a private dwelling.

Arms of Berwick.

The chief public buildings are the town-hall, finished in 1760, a stately building, surmounted by a spire 150 feet high, which contains a peal of eight bells; the new jail, erected in 1849; the corn exchange, which is the principal public hall, opened in 1858; a new infirmary; two assembly rooms; Masonic and Good Templar halls. The parish church is a plain Gothic building, without steeple, of the time of Cromwell. It was thoroughly and tastefully renovated in 1855. The patronage belongs to the dean and chapter of Durham. A week-day lectureship is in the patronage of the Mercers' Company, London. There are also in the borough, including Tweedmouth and Spittal, three other churches connected with the Church of England, three with the Church of Scotland, four United Presbyterian, two English Presbyterian, two Methodist, one Baptist, and one Roman Catholic. The only church building worthy of notice is Wallace Green United Presbyterian Church, opened in 1859. New cemeteries were opened at Berwick in 1855, and at Tweedmouth in 1858. The town is well supplied with educational institutions; and a local museum was established in 1867, where lectures are delivered during the winter. The town and suburbs have four public reading-rooms, and three newspapers are published. Two bridges connect the town with the south side of the Tweed. The older, which is very substantial, was finished in 1634, having taken twenty-four years in building. It has fifteen arches, and is 924 feet long, but only 17 feet wide. The other, situated a quarter of a mile up the river, is a magnificent railway viaduct, 126 feet high, with twenty-eight arches, which extends from the railway station—a castellated building on part of the site of the old castle—to a considerable distance beyond the river. This bridge was opened by Queen Victoria in 1850.

The Tweed is navigable as far as the old bridge, and the tide flows seven miles further. The entrance to the harbour has been improved and protected by a stone pier, built about sixty years ago, which stretches half a mile S.E. from the north bank of the river's mouth, and has at the extremity a lighthouse with two fixed lights. The depth of water at the bar is 17 feet at ordinary tides, 22 feet at spring tides, but the channel is narrow, a large rocky portion of the harbour on the north side being dry at low water. A long-felt want is now being supplied by the construction of a dock, which was begun at Tweedmouth, September 1873. The number of vessels belonging to the port (1875) is 25 (tonnage, 1459). There entered in 1873, 422 (tonnage, 35,049), and there cleared 424 (tonnage, 35,252). The principal exports are grain, meal, herrings, burnt ore, metal castings, manures; the imports are bones and bone-ash, manure stuffs, linseed, salt, timber, pig-iron. The sea-fisheries employ 230 boats in white fishing, 294 in herring fishing, and 52 in both. Berwick, which has long been famous for its salmon fisheries, is the headquarters of the Fishing Company, which occupies most of the stations on the neighbouring coast and for some miles up the river. The fish are mostly sent to the London market. There is an annual fair held here in the end of May, and the weekly market on Saturday. There are four banking establishments; and, on the whole, the trade of the town is increasing.

The ancient charter of the borough of Berwick was confirmed by various sovereigns from Edward I. to James I., who added new officers and privileges, but especially gifted to the burgesses all the lands within the liberties which were not private property. These lands, amounting to 3077 acres, or two-thirds of the whole, are partly divided into farms, partly into meadows occupied or let by the resident freemen and freemen's widows. The annual value of a meadow, seniority determining the allocation, ranges at present from £11, 5s. to £2, 9s. 3d. The roll of freemen contains about 1000, of whom 368 are

resident. The total rental of the corporation's property is now about £10,800. Since the Municipal Reform Act, 1835, the borough has been governed by six aldermen and eighteen councillors; and in 1842 "the power of life and death" was removed from the Quarter Sessions to the Newcastle Assizes. The custom of specially mentioning Berwick-on-Tweed after Wales, though abandoned in Acts of Parliament, is still retained in certain proclamations. The title of "county in itself" also helps to recall its ancient history. It is the seat of a Poor Law Union, and the rateable value of the borough (1875) is £53,195. Berwick has sent two members to the English parliament since the reign of Mary. The registered electors number 1285, of whom 368 may vote as freemen, about 200 being doubly qualified. Population in 1871, 8731, or, including the conjoined townships (Tweedmouth, 2809, and Spittal, 1742), 13,282.

Of the origin or early history of Berwick nothing is known. It probably sprung into importance during the long struggle between the Scots and Saxons for the possession of Lothian and the Merse. Egfrid, king of Northumbria, seeking to extend his boundary beyond the Forth, was routed at Dunnichen, 685, and driven back to the Tweed. But it was not until the battle of Carham, 1018, that the latter river was finally secured as the boundary, and Berwick obtained the frontier position to which it owes its fame. It seems rapidly to have grown in size, wealth, and influence. Its name occurs as a royal burgh in the reign of Alexander I., along with Edinburgh, Roxburgh, and Stirling, and with them, from David I., it elected the tribunal which from their number was called the "Court of the Four Burghs." The castle of Berwick was one of the strongholds given up to Henry II. of England to be security for the homage due by William the Lion as the price of his liberty, but it was restored with the others by Richard Cœur-de-Lion in 1189. At Berwick took place several of the conferences held between Edward I. and the competitors for the Scottish crown, and his decision in favour of Baliol was given in the castle, Nov. 1292. Four years later Edward marched north to punish his rebellious vassal, and began his invasion by an attack upon the town which was at once the key of the kingdom and its commercial capital. The English king, familiar with the place, and infuriated by the repulse of his fleet in the river, led the land attack in person. Being very slightly fortified the town was speedily stormed, and no mercy was shown to the inhabitants. One memorable incident is recounted. A company of trading Flemings held out against the besiegers in their fortified building, the Red Hall, until it was set on fire. They were bound by their charter to defend it to the last extremity against the English, and they perished in the flames. Berwick never recovered commercially from the massacre and pillage of this terrible Good Friday. Its efforts again to rise were hindered by the ever-renewed Border warfare, and it gradually sunk to the rank of an ordinary market-town.

On Edward's return from his victorious march through Scotland, he determined to make the town impregnable with stone walls, but before his commands could be accomplished it was recaptured by the Scots as a consequence of the English defeat at Stirling Bridge. On Edward's approach the following year, however, the Scots retired, and during the remainder of his reign it continued in the hands of the English. Here, in 1305, one quarter of Wallace's body was exposed, and shortly afterwards the countess of Buchan was suspended in a cage from one of the castle towers, as a punishment for courageously performing the privilege of her family by placing the crown on King Robert Bruce at Scone. Edward II. spent the winter of 1310 at Berwick after an ineffectual invasion of Scotland. Here, too, on June 11, 1314, the great English army assembled which was defeated a fortnight later at Bannockburn. In 1318 the town, now well fortified, was captured by Bruce, through the help of one of the garrison; a siege by Edward, which followed, rendered famous by the engines employed both in the river and land attacks, was not successful. It remained in the hands of the Scots till 1333, when it was besieged by Edward III., and the hope of relief by the Scottish army being disappointed by their defeat at Halidon Hill, about 2 miles from Berwick, the town and castle were immediately according to agreement, delivered up to the English king The next 130 years saw Berwick occasionally attacked by the Scots, and sometimes with success, but they held it only for short periods until 1461, when Henry VI., in gratitude for refuge after the battle of Towton, made it over to them. In 1482, during the disputes between James III. and his nobles, it surrendered to the English army, and was never retaken by the Scots. Henceforward it occupied in Scotland, in relation to England, the position for long of Calais in France—an important stronghold, the sole remnant of wide-spread conquest. This position explains the possession by Berwick, until the union of the crowns, of a civil and military establishment (with lord-chancellor, lord-chamberlain, Domesday Book, governors of town and castle, &c.) resembling that of a small kingdom. It was that appointed by Edward I. for all Scotland, and was ready to expand, as it had been compelled to contract its sphere, should more territory be again acquired north of the Tweed.

BERWICKSHIRE, a maritime county of Scotland, forming its S.E. extremity, bounded N.E. by the German Ocean, N. by Haddington, W. by Midlothian, S.W. by Roxburgh, S. by the Tweed, which separates it from Northumberland, and S.E. by the liberties of the town of Berwick. Its greatest length from E. to W. is 31¼ miles; its greatest breadth 19½; area about 464 square miles, or 297,161 acres. It is naturally divided into three districts, *Lauderdale*, or the valley of the Leader, in the W.; *Lammermuir*, the upland district occupied by the hills of that name, in the N.; and the *Merse* (probably a corruption of "March" or borderland), the largest district, occupying the S.E. of the county. The Lammermuirs are a range of round-backed hills, whose average height is about 1000 feet, while the highest summit, Sayrs Law, reaches 1753 feet. From these hills the Merse stretches to the S. and E., and is a comparatively level tract of country, traversed, however, from N.W. to S.E. by distinct parallel ridges. The coast line is lofty, rocky, and precipitous, broken by ravines, and not accessible, except at Eyemouth harbour, for small vessels, and at one or two other places for fishing-boats. St Abb's Head, a peninsular promontory with a lighthouse upon it, rises to nearly 300 feet. The Eye is the only river of the county which falls into the sea. The others—the Leader, the Eden, the Leet, and the Whiteadder with its tributaries, the Blackadder and the Dye—all flow into the Tweed. Of these the largest and most important is the Whiteadder, which has its source on the East-Lothian side of the Lammermuirs, and, following a sinuous course of 35 miles, falls into the Tweed within the "Bounds" of Berwick. The climate of Berwickshire is chiefly influenced by its maritime position. The winter is seldom severe in the lowland districts; but spring is generally a trying season on account of the east winds, which often continue into summer. Drainage has remedied the former excessive humidity, and the climate is now excellent, in relation both to the health of the inhabitants and to the growth of vegetation.

Berwickshire, geologically, consists of Silurian rocks in the hilly region, Devonian or Old Red Sandstone in the south-west, and carboniferous limestone in the Merse. Large masses of porphyritic and trap rock occasionally occur, of which St Abb's Head is an example. The sea-cliff to the north-west of the mouth of the Eye is formed of conglomerate or pudding-stone. There is an interesting and somewhat famous geological appearance at a point called Siccar, near Cockburnspath, where the sea has laid open very plainly the junction of the primary and secondary strata.

The soils of Berwickshire are extremely various. On the same farm a great diversity may be found. Along the rivers is a deep rich loam, resting on gravel or clay, chiefly the former. The less valuable clay soil of the Merse has been much improved by the effective system of drainage which is everywhere carried out. The more sandy and gravelly soils are suitable for the turnip crops, which are a marked agricultural feature of the county. To these soils the landlords and tenants of Berwickshire have applied themselves with such intelligence, mutual good-will, liberality, and spirit, that the county now stands in the first rank in regard to agriculture. The farms are large, and are commonly held by a nineteen years' lease. Nowhere is farming conducted more scientifically or with better success. According to the agricultural returns for 1874, the total acreage under all kinds of crops, bare fallow, and grass,

was 192,138, or more than three-fifths of the entire area. Of this, 63,526 acres were under corn crops, 34,155 under green crops, 56,940 under clover and grasses, and 36,858 permanent pasture, meadow, or grass not broken up in rotation (exclusive of heath or mountain land). The average extent of land occupied by each occupant was 194 acres. Wheat was grown on 6373 acres; barley or bere, on 21,469; oats, on 33,130; potatoes, on 2593; turnips and swedes, on 30,345. Of live stock there were 5356 horses, 16,979 cattle, 285,578 sheep, 4527 pigs. Though about the twentieth in size of the Scottish counties, Berwickshire stands fifth in the number of acres under corn crops, fifth also in green crops, and ninth in the number of sheep. The farm-buildings are convenient and well built. These include cottages for the farm-labourers, or *hinds*, and their families,—the ordinary staff consisting of a steward, a shepherd, and a number of ploughmen proportionate to the size of the farm. The farm-labourers, who are physically well developed, are as a whole a frugal, industrious, intelligent race. They are somewhat migratory in their habits, being too ready to move from place to place year after year. This feature in their character, which they may have by inheritance as *Borderers*, has admirably fitted them for colonial life, to which the lack of employment in mining or manufactures in the county has largely drawn the surplus population.

The minerals of Berwickshire are insignificant. Coal, copper ore, and ironstone exist in such small quantities that attempts to work them have been abandoned; and the limestone is at too great a distance from a coal district to warrant competition with the adjoining counties. The Tweed salmon fisheries are productive of an important trade, and are so subject to vicissitudes that much attention has been paid to them by means of legislative enactments. The lesser rivers of the Merse are held in high esteem by anglers. Besides Eyemouth there are three villages—Burnmouth, Coldingham Shore, and Cove—engaged in the sea-fisheries, which are of considerable and increasing value. Cod, haddock, herring, ling, lobsters, and crabs are the principal produce. Berwickshire cannot boast of many manufactures. Earlstoun sends out ginghams and woollen cloths. At Cumledge, also, on the Whiteadder, there is a factory for heavy woollen cloths; and four miles further down the river, at Chirnside Bridge, is one of the largest paper mills in Scotland. The other manufactures are all connected with agriculture, such as distilleries, breweries, tanneries, &c. The trade is also mainly agricultural. Fairs are held at Dunse, Lauder, Coldstream, Greenlaw, and Oldhamstocks; but the sales of cattle and sheep are now mostly accomplished at the weekly or fortnightly auction marts at Reston, Dunse, and Earlstoun. The grain markets are held at Dunse and Earlstoun. Berwick, from which the county derives its name, is still its chief market-town. There is, however, no legal or fiscal connection between the county and the borough.

The early history of Berwickshire is to a great extent bound up with that of the ancient frontier town; from its position it also suffered much during the Border wars. The most noteworthy antiquities are Coldingham Priory in the E. and Dryburgh Abbey in the S.W. They were burnt in the same year, 1545, during the barbarous inroad of the English army under the earl of Hereford. About four miles N. from Coldingham are the ruins of Fast Castle ("The Wolf's Crag" of the *Bride of Lammermoor*), situated on a peninsular cliff, 120 feet by 60, and 70 feet above the sea. A little further north is the Pease or Peaths Bridge, built by Telford, in 1786, over the deep glen which forms the celebrated pass—of old one of the strongest natural defences of Scotland. Near it is Cockburnspath Tower, once a strong fortress, now in ruins. In the west of Berwickshire, besides Dryburgh, there are, at Earlstoun, the remains of the ancient tower "The Rhymer's Castle," the traditional residence of Thomas Learmont, commonly called Thomas of Ercildoune or Thomas the Rhymer. About a mile from Earlstoun is Cowdenknowes, on a hill above which grew the "bonnie broom" of the old song. None of it now remains, it having been gradually encroached upon by the plough, and the last of it killed by the severe frost of 1861-62. Hume Castle, the ancient seat of the Home family, also towards the west, has a most commanding view, and is itself visible from nearly every part of the county. Traces of Roman occupation and of ancient British settlements exist in various parts of the Merse. Edin's or Etin's Hall, on Cockburn Law, about four miles north of Dunse, still goes under the name of the Pech's or Pict's House. There are many large mansions throughout the county, the principal being Thirlestane Castle (earl of Lauderdale), Mertoun House (Lord Polwarth), Mellerstain and Lennel House (earl of Haddington), Nesbit (Lord Sinclair), Dunse Castle (Hay), Wedderburn and Paxton (Milne Home), Lees (Sir John Marjoribanks), Ladykirk (Baroness Marjoribanks), Ayton Castle (Mitchell Innes), Hirsel (earl of Home). The chief towns are Greenlaw, the county town, with a population of 823; Dunse, 2618; Lauder, 1046, a royal burgh, which unites with the Haddington group of burghs in returning a member to parliament; Coldstream, 1724; and Eyemouth, 2324, the only seaport of the county. There is one sheriff for the three border counties of Berwick, Roxburgh, and Selkirk, and a sheriff-substitute holds his court in Dunse. Justice of the Peace courts are held at Coldstream and at Ayton, and a burgh court at Lauder. The county is divided into thirty-one parishes, and it returns one member to parliament. Population of Berwickshire, 36,486—males, 17,414; females, 19,072.

The fauna and flora of Berwickshire have been carefully described by the late Dr George Johnston, and further information may be obtained regarding these from the *Transactions of the Berwickshire Naturalists' Club*.

BERYL, a mineral species which includes, in addition to what are ordinarily known as beryls, the aquamarine or precious beryl and the emerald. The similarity between the beryl and the emerald was pointed out by Pliny, and the only points of distinction are the green colour of the emerald and the somewhat superior hardness of the beryl. The colour of the emerald is generally believed to be due to the presence of a minute portion of oxide of chromium, although M. Lewy asserts, from analysis of Muzo emeralds, that it is really owing to the presence of organic matter. Their composition is—

	Beryl.	Emerald.
Silica	67·00	68·50
Alumina	16·50	15·75
Glucina	14·50	12·50
Chromium oxide	0·00	0·30
Iron oxide	1·00	1·00
Lime	0·50	0·25

The metal glucinum, from its presence in the beryl, is sometimes termed beryllium. The beryl crystallizes in six-sided prisms with the crystals often deeply striated in a longitudinal direction; its hardness in the mineralogical scale is from 7·5 to 8, and its specific gravity from 2·67 to 2·732. Leaving out of account the emerald, the colours of the beryl range from blue through soft sea-green to a pale honey yellow, and in some cases the stones are entirely colourless. The aquamarine is so named on account of its bluish green colour, "*qui viriditatem puri maris imitantur*" (Pliny, *N.H.*, xxxvii. 20). The chrysoberylus, chrysoprasus, and chrysolithus of ancient jewellery appear to some extent at least to have been names applied to different shades of beryl. The beryl was highly prized for use in jewellery by the Romans, by whom it was cut into six-sided prisms (*cylindri*) and mounted as ear-drops. Some of the

finest examples of ancient Greek and Roman gem engraving are found executed in beryl. "The grandest intaglio extant of the Roman period is upon an aquamarine of the extraordinary magnitude of 2½ by 2¼ inches: the bust of Julia Titi signed by the artist ΕΥΟΔΟϹ ΕΠΟΙΕΙ. For nearly a thousand years it formed the knosp of a golden reliquiary presented by Charlemagne to the abbey of St Denys, in which it was set with the convex back uppermost, being regarded as an invaluable emerald" (King's *Precious Stones, Gems, and Precious Metals*). The great abundance of aquamarine and other forms of beryl in modern times has very much depreciated its value for use in jewellery, but it is still set in bracelets, necklaces, &c., and used for seals. The finest aquamarine known is a large stone, in size and shape somewhat like a small calf's head, weighing 18 ℔, the property of the emperor of Brazil. A beryl weighing 2900 ℔ and another of 1076 ℔ weight have been found at Grafton, New Hampshire, in the United States; but these gigantic stones are opaque, and of no value for jewellery. Beryl is found widely disseminated, occurring, among other localities, in Siberia, Canjargum in Hindustan, Rio San Matteo in Brazil, Ehrenfriedersdorf in Saxony, and Schlackenwald in Bohemia. In the United Kingdom it occurs in the Mourne Mountains, county Down; in the neighbourhood of Killiney, county Dublin; in county Wicklow; in several places in Cornwall; and in Aberdeenshire in the granite of Rubislaw (Davidsonite); besides occurring in the alluvium of the upper reaches of the Dee and Don. In the United States it is found in the states of New Hampshire, Maine, Massachusetts, Connecticut, and Pennsylvania.

BERZELIUS, JÖNS JAKOB, one of the most illustrious of modern chemists, was born on the 20th of August 1779, at a farm near Wafversunda, in Östergötland, Sweden. At the age of nine he was left an orphan in the charge of his stepfather, A. Elmark of Ekeby, a learned and amiable man, gifted, too, it would seem, with some prophetic insight, for one day he said to the child, "Jakob, I think you will tread in the footsteps of Linnæus, or be another Cartouche!" From that day a desire for distinction as a man of science awoke in the child's breast. In 1793 Berzelius entered the gymnasium school at Linköping, where he made rapid progress. During his holidays, spent in the country, he met a man who instructed him in the elements of entomology, and thus gave a fresh impetus to his scientific proclivities. The latter soon developed into a passion, and under Hornstedt at Linkoping progressed rapidly till he left the college in 1796, and proceeded to the University of Upsala. In 1798 he began to study chemistry under Professor Afzelius; and although in those days the lectures were without practical experiments and extremely uninteresting, he became more and more absorbed in the study. In 1800 he was called to Stockholm as assistant to the royal physician, Dr Hedin, and his success as a practical chemist began. The Italian, Volta, had in 1800 invented the galvanic battery which bears his name; and Berzelius was one of the first persons in Europe to observe the greatness of this discovery. In 1802 he published a treatise on the subject. In 1803 he became professor of physics, and by his lectures rapidly founded a new, a rational school of physiology, and threw new light on many difficult points connected with the chemical and physical characteristics of animal life. In the same year he published his *Essay on the Division of Salts through Galvanism*, in which he propounds the electro-chemical theory, the honour of first laying down which is divided between Berzelius and Davy. In conjunction with Hisinger, Berzelius then published in numbers *Treatises on Physics, Chemistry, and Mineralogy*, a work of the greatest value for science. Honour after honour was heaped upon him; in 1810 he was called to be a member of the Medical College of Sweden; in 1808 he was elected president of the Academy of Sciences. Two years later he brought out his famous treatise *On the Fixed Proportions and Weights of Atoms*. He then took up mineralogy with special ardour, and published his *Treatise on the Blowpipe;* he set up for himself a regularly graduated chemical system of minerals, and the value of this was felt to be so great that the Royal Society of London voted him its gold medal for it. After incessant labour he retired, in 1832, from his professorship at Stockholm, having never been connected as teacher with any of the universities. In 1842, while he was engaged in a chemical experiment, an explosion took place and he was much injured, but recovered and continued to work on till the close of his days. He died August 7, 1848. After Linnæus, his is considered to be the greatest name in science of which Sweden can boast.

BES, the name of an Egyptian god, apparently the same as that of the city Bessa. He is stated to have been worshipped and to have had an oracle at Abydos according to Ammianus Marcellinus,[1] and according to others at Antinoe or Antinoopolis. The name *Bes* is found in Egyptian monuments attached to a god clad in a lion's skin, the head and skull of the animal covering his head and concealing his features; his legs are bowed like Ptah, and his whole appearance is grotesque, resembling in other respects the Greek Hercules. This god is represented at a later period in various attitudes and actions, in adoration to Harpocrates, styled his lord or master, playing on the tambourine, the triangular harp, and other musical instruments, brandishing swords, and at the Roman period armed in the paludamentum and holding a sword and buckler. Although supposed to be a form of Typhon he is quite distinct from Set, the ass or gryphon-headed god. For head attire Bes often wears a kind of cornice surmounted by four or five feathers of the hawk. He does not appear among the deities of Egypt till about the 19th or 20th dynasty, and is apparently of foreign origin, being found on the coins of Gaulos, with Phœnician legends, as if belonging to that people and a form of Baal. He appears in the *Ritual* as the guardian of the 20th Pylon or doorway of the Aahlu or Elysian fields, with his mystical names. His head generally surmounts the little cippi of Harpocrates, and some texts ally him with the god Amen. A temple in Nubia, built by Tirhakah about 690 B.C., has its columns in shape of this god. His figures and busts are common in Egyptian art of a later age, and individuals were called after him both in earlier and later times.[2]

BESANÇON, a city of France, capital of the department of Doubs, 45 miles E. of Dijon, on the River Doubs, which flows round it on three sides. It is well protected by strong fortifications and a citadel on an almost impregnable rock, 410 feet above the river. The town is in general well built, and has three main streets running from N. to S. The principal buildings are the Gothic cathedral of St Jean, a court-house, a town-hall, the Granvelle palace, the royal college, an arsenal, a large hospital, barracks, a theatre, a library of 300,000 volumes, a museum and picture gallery, and several handsome fountains. Among the numerous Roman remains are a triumphal arch erected in honour of Crispus Cæsar, son of Constantine, a theatre, and an amphitheatre. Besançon is the see of an archbishop, has tribunals of primary jurisdiction and commerce, and is the head court for the departments of Doubs, Jura, and Haute Saône. It possesses also a university-academy, a diocesan seminary, a royal academy of science and

[2] Birch, *Gallery of Antiquities*, p. 47.

belles-lettres, a lyceum, an antiquarian museum, a society of agriculture, and schools of medicine, artillery, and design, besides two deaf and dumb institutions. The chief branch of industry is the manufacture of watches and jewellery. There are also some considerable breweries and manufactories of carpets, porcelain, hardware, Seltzer-water, artificial flowers, &c. Besançon enjoys a good position for the commerce between France and Switzerland. Population in 1872, 39,868. Long. 5° 56′ 26″ E., lat. 47° 14′ 12″ N.

Besançon is a place of great antiquity. Under the name of *Vesentio*, it was, in the time of Cæsar, the chief town of the Sequani. Under the Roman emperors it was rich and prosperous, and Aurelian especially had a great liking for the place. Many of the streets still bear the old Roman names. It was frequently destroyed and rebuilt during the Middle Ages, and the present city stands twenty feet above the original level. In the 12th century it passed with the rest of Franche-Comté to the German empire, and was made a free city by Frederick I. In 1584, Granvilla, the minister of Charles V. became archbishop of the see, and afterwards founded a university in the town, which existed till the Revolution. By the treaty of Westphalia, Besançon was made over to Spain, and many traces of Spanish occupation still remain. In 1660 Louis XIV. besieged it in person, and it was assigned to France by the peace of Nimeguen. In 1814 and 1815 it was invested and bombarded by the allies; and in the war of 1870–71 it formed an important position in the movements of the French army.

BESKOW, Bernhard von, Baron, the Swedish dramatist, was born at Stockholm, April 19, 1796. Beskow's first book, *Poetical Efforts*, published in 1818, made a favourable impression with the public, and he wrote the prize poem for the Swedish Academy some years later. His dramas, however, are his chief claim to remembrance; the best are *Torkel Knutsson*, *Erik XIV.*, *Birger and his Race*, and *Gustavus Adolphus in Germany*. *Torkel Knutsson* is considered the finest drama that Swedish literature possesses. In the highest sense of the word, these are not, however, dramas at all, since they lack unity and fail in the development of character, but they are grandiose historical studies in a dramatic form. Beskow's poetry is over-decorated with phrases, and becomes the prey of sonorous antithesis. Besides lyrical and dramatic poetry, Baron von Beskow distinguished himself in history, philosophy, politics, and travels. In 1828 he was elected president of the Swedish Academy, and became an enthusiastic and liberal patron of national poetry and art. Œhlenschläger translated his dramas into Danish, and various persons rendered them into German. He died on the 17th of October 1868.

BESSARABIA, a government in the S.W. of European Russia, on the borders of Austria and the Danubian principalities, with an area, since the cessions of the Paris peace in 1856, of 14,577 English square miles. Till the last Eastern war Bessarabia occupied the whole space between the Dniester and the Pruth from the Austrian frontier to the Black Sea. The northern portion of Bessarabia is mountainous, the southern flat and low,—the limit between the two being marked by the so-called upper Trajan wall, an artificial elevation executed, according to some, in the end of the 2d century A.D., under Trajan, but, according to others, in the 3d century, under Probus. This wall extends from the confluence of the Botna with the Dniester to the Pruth. In northern or mountainous Bessarabia two systems of elevations may be distinguished. The first is an immediate offshoot of the Carpathians, and occupies the whole of Khoteen, or the north-western district of the government. It rises about 450 feet above the valley of the Dniester, and consists of strata of Palæozoic formation, sandstones, schists, and limestones. The second system is especially extended in the very middle of Bessarabia, and may be called the Yassa-Orgievian range. It consists of limestone of secondary formation, and its highest point is Mount Megura, about 20 miles S. of Bielitz, between Bakhmut and Poltava. The low portion of Bessarabia stretches south from the Trajan wall, with a length of 133 miles and a breadth of 33, and is well known as the Budjak steppes. The surface is perfectly level; and the soil, except in the region along the shore, consists of a thick bed of loam. The province is washed on its eastern parts by the Black Sea only for the distance of 20 miles to the south of the estuary of the Dniester. Its only seaport is that of Akerman, situated on the estuary of the Dniester. This river divides Bessarabia from Kherson and Podolia for a distance of almost 600 miles. The shores of the Dniester are in general high and steep, and numerous bars obstruct its channel, particularly at Yampol and Bakat. On the Bessarabian bank are situated the towns Khoteen, Cosoka, and Bender; and thirteen natural harbours for ships are counted along this side of the river. Among the principal tributaries are the Reuth, the Ikel, the Buik, and Botna. Another important stream is the Pruth, of which the left shore skirts the province for a distance of more than 140 miles. The navigation on the Pruth is not important; its course is impeded by bars and falls. The only important lakes in the government lie along the coast of the Black Sea in the Akerman district. Marshes extend along the Reuth and its tributaries, and there are also some along the Botna; they offer no great obstacles, however, to free communication. Bessarabia up to 1856 possessed great quantities of sedimental salt; but after the cessions of the Black Sea coast and the salt lakes, the quantity obtained, which formerly exceeded 60,000 tons, almost came to nothing. The climate of Bessarabia is temperate. The medium annual temperature of Keesheneff, 230 feet above the sea-level, is 50° Fahr.; the temperature of the warmest month, about 73°; of the coldest, about 20°. In the valley of the Dniester the climate is in general much healthier than in that of the Pruth; the climate of the north-west is much colder, and spring commences there ten days later.

In all the upper part there are forests, consisting principally of beech, oak, and sorb, besides small quantities of birch. The chief forest region lies along the heights of the Orgieff and Yassa districts about the Megura Mountains, and extends thence east to the Dniester and south-west to Keesheneff. The Khoteen hills are almost all covered with timber. The three northern districts, Khoteen, Bielitz, and Soroka, are especially suited for agriculture, and may be regarded as the granary of Bessarabia. The two intermediate districts of Orgieff and Keesheneff, though possessing a sufficiently fertile soil, are pre-eminently woodland; while the two southern, Bender and Akerman, although also fertile, have a steppe-like character, and are better adapted to the rearing of cattle.

Bessarabia, in keeping with its position near the Danube, played an important historic part in ancient times, especially in the beginning of our era, when it served as a key to the eastern approaches of the Byzantine empire. And thus, from immemorial times, nations were ceaselessly alternating with nations within its borders. The original inhabitants were the Cymri, succeeded by the Scythians. Herodotus, who had been in the Greek colonies of the Black Sea, relates that near the mouth of the Dniester (Tyras) there lived the Tyritians, possessing on the estuary of that river the town of Tyrus (Oxeia or, according to Pliny, Ophiusa). In 1367 Bessarabia formed a part of

ern portion of the country, or Budjak, fell under the power of the Turks; and in 1560 there settled in that district 30,000 Nogaitzians, who had devastated northern Bessarabia, then inhabited by Roumanians. These Nogaitzians acquired the name of the Bielgorod horde. Russian armies occupied Bessarabia during all the Turkish wars in the 18th century, and again in 1806–12, when it was united to Russia by the Bukharest treaty. By the Paris convention of 1856, Russia ceded the districts of Ismael and the greater part of the Cagul to Turkey, and these now form a part of Roumania. At present the government is divided into seven districts, those of Kecsheneff, Akerman, Bender, Orgieff, Soroka, Khoteen, and Yassa. Bender and Akerman are subdivided into five cantons, each of the others into four. In 1860 the population numbered 988,431, and had a very varied ethnographical character. The principal portion consisted of Moldavians, descendants of the ancient Dacians. The Russnayks or Galicians and Rœyani (that is, those who have inhabited the rœyas provinces of the Turkish empire), amounted to 130,000, mostly found in the districts of Khoteen, Soroka, Yassa, and Orgieff. Malo-Russians (or Little Russians) began to settle in the country in the 17th century, and now number 70,000. The Bulgarians began their immigration from the Turkish provinces in 1806–12, afterwards in 1830–34, and finally after 1856; they number 60,000. These colonies are administratively divided into three circles:— the Upper Budjak, consisting of 19, the Lower Budjak of 19, and the Ismael of 5. The Germans began to settle in Bessarabia in 1814. Their colonies, to the number of 25, are situated in the Akerman district, along the River Cogalnika. The Jews, who number 70,000, live partly in the cities Kecsheneff, Khoteen, &c., but are also settled in 16 agricultural colonies. The Gypsies, or Zigan, amount to 10,000. They live a wandering life; but in the Akerman district two villages, Pharaonofo and Kacra, are permanently inhabited by them. A considerable number of Armenians and Greeks have also settled in the country during the present century.

BESSARION, Johannes, titular patriarch of Constantinople, and one of the illustrious Greek scholars who contributed to the great revival of letters in the 15th century, was born at Trebizond in 1389, or, according to others, in 1395. In 1423 he entered the order of St Basil, and studied under the celebrated Platonic scholar, George Gemistus Pletho. In 1437 he was made archbishop of Nicæa by John Palæologus, whom he accompanied to Italy in order to bring about a union between the Greek and Latin Churches. At the councils held in Ferrara and Florence Bessarion supported the Roman Church, and gained the favour of Pope Eugenius, who invested him with the rank of cardinal. From that time he resided permanently in Italy, doing much, by his patronage of learned men, by his collection of books and manuscripts, and by his own writings, to spread abroad the new learning. He held in succession the archbishopric of Siponto and the bishoprics of Sabina and Tusculum. In 1463 he received the title of patriarch of Constantinople; and it was only on account of his Greek birth that he was not elevated to the Papal chair. For five years he was legate at Bologna, and he was engaged on embassies to many foreign princes, among others to Louis XI. of France in 1471. Vexation at an insult offered him by Louis is said to have hastened his death, which took place, on the 19th November 1472, at Ravenna. Bessarion was one of the most learned scholars of his time. Besides his translations of Aristotle's *Metaphysics* and of Xenophon's *Memorabilia*, his most important work is a treatise directed against George of Trebizond, a violent Aristotelian, and entitled *In Calumniatorem Platonis*. Bessarion, though a Platonist, is not so thoroughgoing in his admiration as Pletho, and rather strives after a reconciliation of the two philosophies. His work, by opening up the relations of Platonism to the main questions of religion, contributed greatly to the extension of speculative thought in the department of theology.

BESSÈGES, a town of France, in the department of Gard, 20 miles north of Alais by railway, of importance for its coal and iron mines and blast-furnaces. Population in 1872, 8036.

BESSEL, Friedrich Wilhelm, a distinguished Prussian astronomer, was born at Minden on the 22d July 1784. At an early age he was placed in the counting-house of a merchant at Bremen. His strong desire to obtain a situation as supercargo on a foreign voyage led him to the study first of navigation and then of mathematics. He devoted himself with the utmost ardour to mathematical and astronomical calculations, and in 1804 undertook the reduction of the observations made on the comet of 1607. His results were communicated to Olbers, who warmly praised the young astronomer, and in 1806 recommended him for the post of assistant to Schröter in the observatory at Lilienthal. In 1810, after his reputation had been much extended by various memoirs, treating particularly of cometary orbits, he was appointed director of the new observatory then being founded by the king of Prussia at Königsberg. He was at the same time made professor of astronomy and mathematics in the university of that town. Bessel, from his keen practical intelligence, thorough acquaintance with all instrumental appliances, and complete mastery of the methods of calculation, was admirably fitted for the post of observer. The establishment at Königsberg was one of the best of its kind, and its observations, published continuously from 1813, are of great value. In 1818 Bessel completed a task on which he had been engaged for several years—the reduction of Bradley's priceless but neglected Greenwich observations. The results were published in the volume entitled *Fundamenta Astronomiæ*, the importance of which for astronomical science cannot be overrated. By its publication the author at once took his place among the first astronomers of Europe; he was received with honour by the various foreign scientific societies, and was made a privy councillor by the king of Prussia. Of his later labours in practical astronomy perhaps the most important is his determination of the parallax of the star 61 Cygni, accomplished by methods of extreme ingenuity and delicacy. The *Tabulæ Regiomontanæ*, 1830, and *Astronomische Untersuchungen*, 2 vols., 1841–42, are continuations of the *Fundamenta*. His memoirs, contained in the *Astronomische Nachrichten*, are exceedingly numerous. A volume of *Popular Lectures* was published by Schumacher after the death of the author in 1846.

BETEL NUT. The name betel is applied to two different plants, which in the East are very closely associated in the purposes to which they are applied. The betel nut is the fruit of the Areca or betel palm, *Areca Catechu*, and the betel leaf is the produce of the betel vine or pan, *Chavica Betel*, a plant allied to that which yields black pepper. The areca palm is a graceful tree, which appears to be indigenous over a wide area in the East, including Southern India, Ceylon, Siam, the Malay Archipelago, and the Philippine Islands, in the whole of which it is extensively cultivated. The fruit of the palm is about the size of a small hen's egg, and within its fibrous rind is the seed or so-called nut, the albumen of which is very hard and has a prettily mottled grey and brown appearance. The chief purpose for which betel nuts are cultivated and collected is for use as a masticatory,—their use in this form being so wide-spread among Oriental nations that it is estimated that one-tenth of the whole human family indulge in betel chewing. For this use the fruits are annually gathered between the months of August and November, before they are quite ripe, and deprived of their husks. They are prepared by boiling in water, cutting up into slices, and drying in the sun, by which treatment the slices assume a dark brown or black colour. When chewed a small piece is wrapped up in a leaf of the betel vine or pan, with a pellet of shell lime or chunam; and in some cases a little cardamom, turmeric, or other aromatic is added. The mastication causes a copious flow of saliva of a brick-red colour, and gives the mouth, lips, and gums of the chewer a repulsive appearance. The habit blackens the teeth, but it is asserted by those addicted to

it that it strengthens the gums, sweetens the breath, and stimulates the digestive organs. Among the Orientals betel is offered on ceremonial visits in the same manner as wine is produced on similar occasions by Europeans. Betel nuts are further used as a source of catechu, which is procured by boiling the nuts in water. The water of the first boiling becomes red and thick, and when this is inspissated after the removal of the nuts it forms a catechu of high astringency and dark colour called in Bombay "Kossa." The nuts are again boiled, and the inspissated juice of the second decoction yields a weaker catechu of a brown or reddish colour. Betel nuts are used to some extent in the United Kingdom as the source of a charcoal tooth-powder, which, however, has no special virtue, and they are also employed by turners for ornamental purposes, and for coat buttons on account of the beauty of their structure. Recently they have come into repute as a vermifuge, and have been admitted into the *Supplement* to the *British Pharmacopœia* (1874) as a cure for tape-worm. The quantity of betel nuts consumed in the East is enormous. Ceylon alone exports about 70,000 cwt. annually; Travancore has upwards of a million of trees, the average produce of each being 300 nuts annually, or about 6000 tons in all; Sumatra is little less productive, and the small island of Penang, named from the Malayan name for the tree, is estimated to contain half a million trees. The nuts of other species of *Areca* are used by the poorer classes in the East as substitutes for the genuine betel nut.

BETHANY (*i.e.*, probably, the "House of Dates"), a village, now called El' Azarîyeh, or Lazarieh, nearly two miles E.S.E. from Jerusalem, on the eastern slope of the Mount of Olives, at a height of 2208 feet above the sea. The whole importance of the place is derived from its connection with New Testament history, it being never mentioned in the Old Testament or Apocrypha. It was the residence of Lazarus and his sisters, a favourite retreat of the Saviour, and the scene not only of his greatest miracle but also of his ascension. From the 4th century down to the time of the Mahometan invasion several ecclesiastical buildings were erected on the spot, but of these no distinct traces remain. Lazarieh is a poor village of about twenty families, with few marks of antiquity; and there is no reason to believe that the houses of Mary and Martha and of Simon the Leper, or the sepulchre of Lazarus, still shown by the monks, have any claims to the names they bear.

BETHEL (*i.e.*, in Hebrew, the "House of God"), originally called Luz, an ancient city of Palestine, on the borders of the tribe of Benjamin, eleven English miles north of Jerusalem. Of the origin of its new name two accounts are given in Genesis, both of them, however, connecting it with the history of Jacob. After the conquest of Canaan by the Israelites Bethel became a resting-place of the ark, and at a later date it was chosen as a royal residence and a seat of idolatrous worship by several of the renegade kings. It seems to have continued to flourish down into the Christian era, some remains still existing of its ecclesiastical buildings. Its ruins, which now bear the name of Beitin, occupy about three or four acres.

BETHESDA was a pool or public bath in Jerusalem, where miraculous cures were believed to be performed; now usually identified with the Birket Israel, near St Stephen's Gate. See Jerusalem.

BETHLEHEM (*i.e.*, in Hebrew, the "House of Bread"), a small town in Palestine, situated on a limestone ridge, about six miles from Jerusalem, on the main road to Hebron. It was a place of great antiquity; and, under the name of Ephrata is mentioned in the history of Jacob. From the book of Ruth, which contains the romantic story of some of its inhabitants, it would appear to have had special connection with the land of Moab. At a later date it became famous as the birthplace of David, but does not seem to have received any special favours at his hand. It was fortified by Rehoboam; and the neighbouring inn of Chimham seems to have become a regular rendezvous for travellers proceeding to Egypt. Almost complete obscurity, however, was gathering round it when it became one of the world's most memorable spots—the birthplace of the Saviour. Desecrated during the reign of Hadrian by a grove of Adonis, the traditional scene of the nativity (a grotto on the eastern part of the ridge) was enclosed by the Empress Helena with a noble basilica, which still stands, surrounded by the three convents successively erected here by the Greek, Latin, and Armenian Churches. In the neighbourhood is still shown the traditional grotto where Jerome spent a portion of his life busy with his Latin translation of the Scriptures. Captured by the Crusaders in the 11th century, Bethlehem was made an episcopal see; but the bishopric soon sank into a titular dignity. The present village is well built and clean, and the inhabitants, who number about 3000, profess Christianity. The carving of crucifixes and other sacred mementoes gives employment to a number of persons.

BETHUNE, the chief town of an arrondissement in the French department of Pas de Calais, situated on a rock above the River Brette, 16 miles N.N.W. of Arras. It is strongly fortified, and its defences are partly the work of Vauban. It has a tribunal of primary jurisdiction, a communal college, a Gothic church, two hospitals, and manufactures of linen, cloth, and beer. The trade, chiefly in grain, cheese, linen, and oil, is facilitated by the canal, which unites the Lawe with the Lys. The town, which dates from the 11th century, was taken by the allied forces in 1710, and restored to France by the treaty of Utrecht. Population in 1872, 4594.

BETLIS, Bitlis, or Bedlis, a town of Turkish Armenia, in the Sandjak of Mûsh, situated near the south-west corner of Lake Van, in a highly cultivated valley, which is watered by the Bitlis-chai, a sub-tributary of the Tigris. Partly owing to the irregularity of the ground, the houses are scattered, without much attention to order, and most of them are surrounded with gardens or orchards. The castle of the Bey, a straggling structure, is situated on the lava rock that bounds the valley; while in the centre of the town, on an eminence so steep that it is only accessible by a road winding round it, stand the ruins of an ancient fortress of great strength. Betlis is a great seat of the dancing dervishes, who have twelve convents in the place. The Armenians, who form about a fourth of the population, have four churches and as many monasteries, and the Mahometans possess numerous mosques and medresses. A considerable trade is carried on, as well as the manufacture of gold and silver wares, the weaving of cotton-cloth and carpets, and the preparation of tobacco. According to an Armenian tradition Betlis was founded by Alexander the Great. In 1514 it became a Turkish possession, and it has for about three centuries been held as a fief by a Kurdish family. The population is variously estimated at from 10,000 to 12,000.

BETTERTON, Thomas, the best English actor of his time, was the son of Mr Betterton, under-cook to King Charles I., and was born at Westminster in 1635. He was apprenticed to Mr Rhodes, a bookseller near Charing Cross. Rhodes, who had been wardrobe-keeper to the theatre in Blackfriars, obtained in 1659 a licence to set up a company of players at the Cockpit in Drury Lane; and there Betterton made his first appearance on the stage. On the opening of the new theatre in Lincoln's-Inn-Fields in 1662, Sir William Davenant, the patentee, engaged Betterton and all Rhodes's company to play in his *Siege of*

Rhodes. Betterton became a great favourite with the king, and was sent to Paris to examine the French stage, with a view to the introduction of improvements. According to Cibber it was after his return that shifting scenes were first used in the English theatre instead of tapestry. In 1670 Betterton married Mrs Sanderson, a good actress of the same company; and the marriage was a very happy one. In 1693, when he had just lost the little money he had laid by, he was enabled by the aid of his friends to erect a new playhouse in the Tennis Court in Lincoln's-Inn-Fields. It was opened in 1695 with Congreve's *Love for Love*. But in a few years the profits greatly fell off; and Betterton, infirm through age, and labouring under violent attacks of the gout, determined to quit the stage. On his retirement the public gave him a benefit night, when, though upwards of seventy, he played the part of Valentine in the comedy of *Love for Love*: the profits are said to have amounted to upwards of £500. His performance of Hamlet after this time is particularly mentioned in the *Tatler*. In the spring of 1710 he made his last appearance on the stage in his celebrated part of Melantius in *The Maid's Tragedy*. A rash attempt to reduce the swelling of his limbs by external applications threw the gout into his head, and he died on the 28th of April. His body was interred with much ceremony in the cloisters of Westminster. Betterton was author of several dramatic works which were popular in their day. An estimate of his character and abilities is given in the *Apology for my Own Life*, &c., of his friend and rival Colley Cibber.

BETTINELLI, Saverio, Italian Jesuit and littérateur, was born at Mantua on the 18th of July 1718. After studying under the Jesuits in his native city and at Bologna, he entered the society in 1736. He taught the belles-lettres, from 1739 to 1744 at Brescia, where the Cardinal Quirini, Count Mazzuchelli, Count Duranti, and other scholars, formed an illustrious academy. He next went to Bologna to pursue the study of divinity, and there he enjoyed the society of many learned and literary men. At the age of thirty he went to Venice, where he became professor of rhetoric, and was on friendly terms with the most illustrious persons of that city and state. The superintendence of the college of nobles at Parma was entrusted to him in 1751; and he had principal charge of the studies of poetry and history, and the entertainments of the theatre. He remained there eight years, visiting, at intervals, other cities of Italy, either on the affairs of his order, for pleasure, or for health. In 1755 he traversed part of Germany, proceeded as far as Strasburg and Nancy, and returned by way of Germany into Italy, taking with him two young sons or nephews of the prince of Hohenlohe, who had requested him to take charge of their education. He made, the year following, another journey into France, along with the eldest of his pupils; and during this excursion he wrote his famous *Lettere dieci di Virgilio agli Arcadi*, which were published at Venice with his *sciolti* verses, and those of Frugoni and Algarotti. The opinions maintained in these letters against the two great Italian poets and particularly against Dante, created him many enemies, and embroiled him with Algarotti. In 1758 he went into Lorraine, to the court of King Stanislaus, who sent him on a matter of business to visit Voltaire. Voltaire presented him with a copy of his works, with a flattering inscription in allusion to Bettinelli's *Letters of Virgil*. From Geneva he returned to Parma, where he arrived in 1759. He afterwards lived for some years at Verona and Modena, and he had just been appointed professor of rhetoric there, when, in 1773, the order of Jesuits was abolished in Italy. Bettinelli then returned into his own country, and resumed his literary labours with new ardour. The siege of Mantua by the French compelled him to leave the city, and he retired to Verona, where he formed an intimate friendship with the Chevalier Hippolito Pindemonti. In 1797 he returned to Mantua. Though nearly eighty years old he resumed his labours and his customary manner of life. He undertook in 1799 a complete edition of his works, which was published at Venice in 24 vols. 12mo. Arrived at the age of ninety years, he still retained his gaiety and vivacity of mind, and died on the 13th September 1808. The works of Bettinelli are now of little value. The only one still deserving remembrance, perhaps, is the *Risorgimento negli studj, nelle Arti e ne' Costumi dopo il Mille*, a sketch of the progress of literature, science, the fine arts, industry, &c., in Italy.

BETTING may be defined as the staking or pledging between two parties of some object of material value on the issue or contingent issue of some event or contest. The pursuit (it can hardly be termed a pastime, science, or art) of betting has been in vogue from the earliest days of civilization, commencing in the East with royal and noble gamblers, and gradually extending itself westwards and throughout all classes. In all countries where the English tongue is spoken betting is now largely indulged in; and in the United Kingdom it has spread to such an extent amongst all grades of society during the last twenty years that the interference of the Legislature has been found necessary. The evils it has been productive of are too well known to call for comment here, and the principles require to be treated solely from mathematical and legislative points of view.

The first principle of all betting is that "you cannot win where you cannot lose." Accordingly no bets are "play or pay" except those on certain events enumerated below, or unless such a stipulation is laid down at the time the bet is made. Betting may be divided into "bookmaking" and "backing." The former consists in laying the odds, and, theoretically speaking, secures a small though certain profit, were all debts paid and the number of starters for the event large. During the first half of the 19th century bookmaking was a far more lucrative business than now, because betting was confined to the wealthier classes and bad debts were fewer. Also, betting commenced many months before a great race, and so the bookmaker had more opportunities of laying against all the entries, whereas most betting on play or pay events is now done just before the start. Taking the St Leger (always a play or pay event) of 1875, the following table represents a £100 book opened a week before the race, according to the Continental betting quotations, September 7, 1875. Those marked † did not eventually start.

6 to 1	against	Gilbert	£100	to	£16	13	4
7 ,, 1	,,	St Cyr	,,	to	14	5	8
7 ,, 1	,,	Earl of Dartrey	,,	to	14	5	8
10 ,, 1	,,	Dreadnought	,,	to	10	0	0
10 ,, 1	,,	Balfe	,,	to	10	0	0
12 ,, 1	,,	†Bay of Naples	,,	to	8	6	8
16 ,, 1	,,	Rabagas II.	,,	to	6	5	0
16 ,, 1	,,	Seymour	,,	to	6	5	0
20 ,, 1	,,	New Holland	,,	to	5	0	0
25 ,, 1	,,	Breechloader	,,	to	4	0	0
25 ,, 1	,,	Perkin Warbeck	,,	to	4	0	0
25 ,, 1	,,	Craigmillar			Winner.		
25 ,, 1	,,	†Claremont	,,	to	4	0	0
33 ,, 1	,,	†Repentance Colt	,,	to	3	0	7
33 ,, 1	,,	†Salvator	,,	to	3	0	7
40 ,, 1	,,	Saint Leger	,,	to	2	10	0
40 ,, 1	,,	†Temple Bar	,,	to	2	10	0
50 ,, 1	,,	†Telescope	,,	to	2	0	0

50 ,, 1	,,	†Sister to Musket	,,	to	2	0	0
					£120	2	6

In this instance twenty horses are quoted in the betting. Assuming that the bookmaker finds a customer to back each of these, and that he encounters no bad debts, he receives £120, 2s. 6d., and has to pay £100 to the person with whom he laid £100 to £4

against Craigmillar, the winner. This leaves a gain of £20, 2s. 6d. or 20½ per cent., but even then travelling and other expenses have not been taken into consideration, and the fewer horses that are backed the less accordingly will be the bookmaker's profit. In fact, the non-backing of any one horse in this instance materially reduces the profit. The race in question was particularly favourable for bookmakers, both because so many horses were scratched (representing a gain of £26, 17s. 10d.), and because at the date supposed the winner was at such long odds. At the actual start the odds against the beaten horses were 9 to 2, and 6, 7, 9, 10, 12, 20, 25, 25, 50, and 66 to 1 respectively, and against the winner 20 to 3. This will be found to leave the bookmaker, had he commenced his book the day of the race, a profit of £1, 12s. 6d. only, and had the first favourite won there would have been a loss of £5, 11s. 11d. There were 178 entries for this St Leger, and if the book had been opened many months before the race, and the bookmaker had been able to obtain customers, the favourite would have been backed at longer odds, bringing less profit from this source, but then more eventual non-starters are backed, which is certain profit. The chief principles of bookmaking are the same, whether the number of starters for an event be unlimited, or two only, though, in the latter case, there is no certain profit, as there are not sufficient starters to enable the bookmaker to save his stake. His only chance then is that he has been circumspect enough to have laid his odds on the winner.

"Backing" is a very plain matter, but in the long-run invariably a losing method of betting. It simply consists in taking the odds laid by a bookmaker against one or more starters for any event. If it be a play or pay event, and the possible starter be scratched, the backer loses his money at once. Although a backer may become possessed of such special information as may enable him to win large sums occasionally, his losses will in the long-run exceed them. In fact, the bookmaker virtually keeps a bank against him.

"Hedging" consists in laying off at shorter odds part of the sums various starters may have been backed for. Thus, a backer has taken £50 to £1 about A, B, and C respectively for a play or pay event some time before the date fixed for the contest. A turns out a non-starter, so there is a certain loss of £1. At starting the odds have come down to say 2 to 1 against B, and 3 to 1 against C. So the backer lays £50 to £25 against B, and £50 to £16, 13s. 4d. against C. If neither wins he receives £41, 13s. 4d., out of which he has to pay £3 to the bookmaker, leaving a profit of £38, 13s. 4d. Should B win he receives £50 from the bookmaker, and £16, 13s. 4d. on account of C's defeat, out of which he has to pay £2 to the bookmaker on account of A and C, and the £50 he has laid against B, so the profit left is £14, 13s. 4d. Should C win, the hedger receives £50 from the bookmaker, and £25 on account of B's defeat, out of which he has still to pay the bookmaker £2 on account of A and B, and the £50 he has laid against C, so the profit left is £23.

The only events that are now play or pay are the Derby, Oaks, St Leger, Two Thousand Guineas, One Thousand Guineas, Cesarewitch, and Cambridgeshire Stakes, the Ascot, Goodwood, and Doncaster Cups, and all handicaps above £200 value, with two forfeits, the minor whereof is not less than £5. In all other betting the backer is entitled to a start for his money, unless the contrary is stipulated at the time the bet is made.

In the United Kingdom betting has been the source of considerable legislation during the past thirty years. Curiously enough, by the 9th of Queen Anne, if any one gained over £10 by betting, the loser was entitled to pursue for repayment of the stake if he had paid it, and if he did not do so within three months any one might sue for treble the amount with costs. After it had become a dead letter some informers raked up this Act in 1844, and the result was the insertion of a clause in the Gaming Act, 8 and 9 Vict. c. 109, annulling the old statute. During the next seven years betting on horse races increased to an enormous extent. "List shops," where the proprietors kept a bank against all comers, and backers could stake their money in advance on a horse, sprung up in the metropolis and large towns, leading to many acts of flagrant dishonesty. Sir Alexander Cockburn, then attorney-general, accordingly introduced the Betting Houses Act, 16 and 17 Vict. c. 119, whereby all houses or places kept for such purposes were brought under the above-mentioned Gaming Act, and might be proceeded against as a common nuisance and contrary to law,—heavy penalties being incurred by the owners, occupiers, or advertizers of such houses or places. Betting on race-courses, or at Tattersall's and similar private clubs, where money is not received in advance, was not meant to be interfered with. For some time this legislation had the desired effect till attempts were made to evade it by receiving money through the post. These were successful till the summer of 1869, when the Government suddenly bestirred itself, and several prosecutions took place. As the Act, however, did not extend to Scotland, the betting-house keepers removed there or went abroad, and their advertisements at such addresses were still legal. This led to 37 Vict. c. 14, extending 16 and 17 Vict. c. 119 to Scotland, and making all advertisements of betting-houses, whether in or out of the United Kingdom, illegal. It came into force on 31st July 1874, and almost exterminated the receiving of money in advance, especially as it is now enforced very strictly.

In 1866 a system of betting, termed *Paris mutuels*, was started in France. It consisted of agencies where any one may back a probable starter for any sum or sums he pleases. The whole of the money thus staked on all starters is added together, a commission deducted by the agent for his trouble, and the balance divided in "equal shares," or *Paris mutuels*, amongst those who have backed the victor. In this instance the agent's gain is, of course, certain. It has been found, however, that unlicensed opportunities of staking money in advance have produced the same evils in France as in England. During the past three years the French Government have taken the matter up strongly, and betting-houses and agencies are now as effectually doomed on the French as on the English side of the Channel.

In the United States betting is also illegal. Under the Gambling Act, whenever any money has been staked for a bet, either side can sue the stakeholder and recover his portion of the money, either before or after the bet has been decided. Owing, however, to the strong public sentiment which naturally condemns such a course, proceedings against stakeholders are excessively rare. Any voter betting on the result of an election forfeits his franchise, yet the heaviest betting in the States is on elections, and the betters go unchallenged to the poll. (H. F. W.)

BETUL, a hilly district of British India, in the Central Provinces, comprising the westernmost section of the great Sátpurá plateau, situated between 21° 20′ and 22° 35′ N. lat., and 77° 20′ and 78° 35′ E. long. It is bounded on the N. by the Hoshangábád district and the Makrái territory, on the E. by the district of Chhindwárá, on the S. by the commissionership of West Berars, and on the W. by the district of Hoshangábád. The area is about 4118 square miles; the population, as ascertained by the census of 1866, 258,335. In 1872 the population had increased to 284,055, of whom 168,788 were Hindus, 4555 Mahometans, 937 Buddhists and Jains, 19 Christians, and 109,756 aborigines; population, 69 per square mile. The mean elevation of the district above the sea is about 2000 feet. The country is essentially a highland tract, divided naturally into three distinct portions, differing in their superficial aspects, the character of their soil, and their geological formation. The northern part of the district forms an irregular plain of the sandstone formation. It is a well-wooded tract, in many places stretching out in charming glades like an English

park, but it has a very sparse population and little cultivated land. In the extreme north a line of hill rises abruptly out of the great plain of the Narbadá valley. The central tract alone possesses a rich soil, well watered by the Machná and Sámpna rivers, almost entirely cultivated and studded with villages. To the south lies a rolling plateau of basaltic formation (with the sacred town of Multái, and the springs of the River Taptí at its highest point), extending over the whole of the southern face of the district, and finally merging into the wild and broken line of the Gháts, which lead down to the plains. This tract consists of a succession of stony ridges of trap rock, enclosing valleys or basins of fertile soil, to which cultivation is for the most part confined, except where the shallow soil on the tops of the hills has been turned to account.

The principal rivers of the district are the Taptí, Wardhá, Bel Machná, Sampná, Morar, and Tawá. The Taptí rises a few miles from Multái, traverses the southern part of the district, and then plunges into the gorge of the Sátpurá hills, formed on the one side by the Chikaldá hills of Berar, and on the other side by the wild Kálíbhít hills of Hoshangábád. The Wardhá can hardly be called a river of the district, as it merely takes its rise in the Sátpurá hills on the south-eastern boundary. The River Bel also rises in the high plateau of Betul, and forms one of the chief affluents of the Kanhán. The Machná and Sampná rise among the hills that shut in the rich basin of the district. They unite their waters at the town of Betúl, force their way through the Sátpurá range, and join the Tawá near Sháhpur. The Moran rises in the Sátpurá hills within the district, and enters Hoshangábád near the town of Seoní. The Tawá rises in Chhindwárá, and flowing for a short distance through the north-east corner of this district, eventually joins the Narbadá above Hoshangábád. These are the rivers of importance; but throughout the district, and more especially amid the trap formation, there are a number of smaller streams useful for irrigation. The principal agricultural products of the district are wheat and pulses, more than three-fourths of the open lands being devoted to these crops. The other products are cotton, rice, millet, rye, sugar-cane, and opium. The area under sugar-cane cultivation is estimated at 2400 acres, the juice extracted from it being exported in its raw state. The principal agricultural tribe is the Kunbís, many of whom are modern immigrants from Northern India. The aboriginal Gonds are found in all the wild jungle villages, where they follow the nomadic system of cultivation known as the *dáhya*. Extensive forests occupy some 700 square miles of the district area, and yield teak and other good timber. Coal occurs in many parts of the district, but is not worked, as except at one place not a single seam has been found exceeding 3 feet in thickness, and it is doubtful if a seam of that thickness can be profitably mined in India. District revenues in 1868-69—land revenue, £19,159; excise, £7219; assessed taxes, £1136; forests, £1218; stamps, £2743; total, £31,475. Strength of regular constabulary and town police, 333 men; cost, £3857 per annum.

Little is known of the early history of the district except that it must have been the centre of the first of the four ancient Gond kingdoms of Kherlá, Deogarh, Mandla, and Chándá. According to Farishtá, these kingdoms engrossed in 1398 all the hills of Gondwáná and adjacent countries, and were of great wealth and power. About the year 1418 Sultán Husain Sháh of Málwa invaded Kherlá, and reduced it to a dependency. Nine years later the Rájá rebelled, but although with the help of the Báhmíni kings of the Deccan he managed for a time to assert his independence, he was finally subdued and deprived of his territories. In 1467 Kerlá was seized by the Báhmíni king, but was afterwards restored to Málwa. A century later the kingdom of Málwa became incorporated into the dominions of the emperor of Delhi. In 1703 a Musálman convert of the Gond tribe held the country, and in 1743 Raghují Bhonslá, the Marhattá ruler of Berar, annexed it to his dominions. The Marhattás in the year 1818 ceded this district to the East India Company as payment for a contingent, and by the treaty of 1826 it was formally incorporated with the British possessions. Detachments of British troops were stationed at Multái, Betul, and Sháhpur to cut off the retreat of Apá Sáhib, the Marhattá general, and a military force was quartered at Betul until June 1862. The ruined city of Kherlá formed the seat of government under the Gonds and preceding rulers, and hence the district was, until the time of its annexation to the British dominions, known as the "Kherlá Sarkár." The town of Multái contains an artificial tank, from the centre of which the Taptí is said to take its rise; hence the reputed sanctity of the spot, and the accumulation of temples in its honour.

The climate of Betul is fairly salubrious. Its height above the plains and the neighbourhood of extensive forests moderate the heat, and render the temperature pleasant throughout the greater part of the year. During the cold season the thermometer at night falls below the freezing point; little or no hot wind is felt before the end of April, and even then it ceases after sunset. The nights in the hot season are comparatively cool and pleasant. During the monsoon the climate is very damp, and at times even cold and raw, thick clouds and mist enveloping the sky for many days together. The average annual rainfall is 40 inches. In the denser jungles malaria prevails for months after the cessation of the rains, but the Gonds do not appear to suffer much from its effects. Travellers and strangers who venture into these jungles run the risk of fever of a severe type at almost all seasons of the year.

BETWÁ, a river of India, which rises in the native state of Bhopál in Málwa, and after a course of 360 miles, for the most part in a north-easterly direction, falls into the Jamná at Hamírpur in 25° 57′ N. lat. and 80° 17′ E. long.

BEUDANT, François Sulpice, a French mineralogist and geologist, was born at Paris in 1787, and died in 1862. He was educated at the Polytechnic and Normal schools, and in 1811 was appointed professor of mathematics at the Lycée of Avignon. Thence he was called, in 1813, to the Lycée of Marseilles to fill the post of professor of physics. In the following year the royal mineralogical cabinet was committed to his charge to be conveyed into England, and from that time his attention seems to have been directed principally towards geology and cognate sciences. In the year 1818 he undertook, at the expense of Government, a geological journey through Hungary, and the results of his researches, *Voyage Minéralogique et Géologique en Hongrie*, 3 vols. 4to, with atlas, published in 1822, established for him a European reputation. He was about the same time appointed to the professorship of mineralogy in the Paris Faculty of Sciences. His treatises on physics (*Traité de Physique*, 6th ed., 1838) and on mineralogy and geology (*Cours Élémentaire de Minéralogie et Géologie*, 1841) were very popular. Beudant also, when holding the post of inspector of the university, published a valuable French grammar.

BEULÉ, Charles Ernest, a French archæologist and man of letters, was born at Saumur 29th June 1826, and died 4th April 1874. He was educated at the École Normale, and in 1852 was sent to Athens as one of the professors in the École Française established there. At first distinguished as a man of fashion, he afterwards devoted himself with intense vigour to archæological researches. He had the good fortune to discover the propylæa of the Acropolis, and his work, *L'Acropole d'Athènes* (2 vols. 1854), was published by order of the minister of public instruction. Promotion and distinctions followed rapidly upon his first successes. He was made doctor of letters, chevalier of the Legion of Honour, professor of archæology at the Bibliothèque Impériale, member of the Academy of Inscriptions, and perpetual secretary of the Academy of Fine Arts. Like too many French men of letters, he joined eagerly in political affairs, with which the last few years of his life were entirely occupied. The most important of his writings are *Études sur le Péloponnèse*, 1855; *Les Monnaies d'Athènes*, 1858; *Histoire de la Sculpture avant Phidias*, 1864; *Histoire de l'Art Grec*, 1870.

BEUTHEN, the chief town of a circle in the government of Oppeln in Prussian Silesia, on the railway between Oppeln and Cracow, about 50 miles from the former. It is the centre of the mining district of Upper Silesia, and its population, which numbered 15,711 in 1871, is mainly engaged in mining operations. Cloth and linen weaving, however, is also carried on. Beuthen is an old town, and was formerly the capital of the lordship of Beuthen, which belonged to the counts of Donnersmark. It is frequently called Ober Beuthen to distinguish it from the following.

BEUTHEN, or NIEDER BEUTHEN, a town in the government of Liegnitz, in Silesia, on the Oder, and the capital of the mediatized principality of Carolath-Beuthen. The chief industries of the place are straw-plaiting, boat-building, and the manufacture of pottery; and a considerable traffic is carried on by means of the river. Population in 1871, 3826.

BEVERLEY, a market and borough town in the East Riding of Yorkshire, about a mile from the River Hull, with which it communicates by means of a canal called the Beverley Beck. It consists principally of one long wide street, upwards of a mile in length, and terminated by an ancient gateway. The magnificent collegiate church of St John is in size and splendour superior to many cathedrals. Having been erected at different times it exhibits various styles of Gothic architecture. The west front is said by Rickman to be the finest of its kind in England. It is 334 feet in length from east to west; the breadth of the nave and side aisles is 64 feet; the transept is 167 feet long; and the two towers at the west end are 200 feet in height. One of its most remarkable monuments is the Percy shrine. St Mary's church is also an exceedingly handsome and spacious Gothic building. The market-place, which comprises an area of nearly 4 acres, is ornamented with an octangular market-cross. The grammar school is of great antiquity, and has two fellowships, six scholarships, and three exhibitions at St John's College, Cambridge. There are several national and two infant schools, a blue-coat school, a mechanics' institute, a news-room, several banks, a theatre, a jail, and a cattle-market. There is a large trade in grain, timber, and coal. The tanning of leather is the principal industry; but there are also several important manufactories of agricultural implements and of artificial manures, as well as whiting-factories, corn and linseed mills, and breweries and malt-kilns. It formerly returned two members to parliament, but was disfranchised in 1870. Population of municipal borough in 1871, 10,218.

BEVERLEY, a seaport of Massachusetts in the United States, situated on a branch of Ann Harbour, and connected with Salem by a bridge built in 1788. It is 16 miles N.E. of Boston, on the Eastern Railway, and is connected with Gloucester by a branch line. The principal industry is the manufacture of shoes; and a considerable number of people are employed in the coasting trade and fisheries. Population in 1870, 6507.

BEVERLEY, JOHN OF, a celebrated prelate, who flourished during the 7th and 8th centuries, was born at Harpham in Northumbria. He received his education at Canterbury, and after his return to the north was the instructor of the Venerable Bede. In 685 he was made bishop of Hagolstad or Hexham, and two years later was promoted to the archbishopric of York. He resigned his see in 717, and retired to a college which he had founded some years before at Beverley, where he died in 721. He was celebrated for his scholarship as well as for his virtues. The following works are ascribed to him:—*Pro Luca Exponendo* (an exposition of Luke); *Homiliæ in Evangelia; Epistolæ ad Herebaldum, Audenam, et Bertinum; Epistolæ ad Holdam abbatissam.*

BEWDLEY, a market and borough town in the parish of Ribbesford, in the county of Worcester, 129 miles from London, on the Severn Valley Railway. It is well built, and stands on an eminence near the River Severn, over which there is an elegant bridge, erected in 1797. It has a town-hall, a free grammar school, and several charities; and manufactures combs, brass and iron wares, leather, and malt. It returns one member to parliament. Population of parliamentary borough in 1871, 7614.

Bewdley, or, as it was formerly called, *Beaulieu*, was a place of some importance in the 13th century, and had the right of sanctuary for those who shed blood. Henry VII. built a palace in the town for his son Arthur, who was married there by proxy to Catherine of Aragon; but no remains of the building, which was greatly injured during the wars of the 17th century, can now be traced. The town, which was incorporated by Edward IV., formerly belonged to the Marches of Wales, but was assigned to Worcestershire by Henry VIII.

BEWICK, THOMAS, who may be considered as the reviver of wood-engraving in England, was born at Cherryburn, near Newcastle-on-Tyne, in August 1753. His father rented a small colliery at Mickleybank, and sent his son to school at Mickley. He proved a poor scholar, but showed, at a very early age, a remarkable talent for drawing. He had no tuition in the art, and no models save natural objects. At the age of fourteen he was apprenticed to Mr Beilby, an engraver in Newcastle. In his office Bewick engraved on wood for Dr Hutton a series of diagrams illustrating a treatise on mensuration. He seems thereafter to have devoted himself entirely to engraving on wood, and in 1775 he received a premium from the Society for the Encouragement of Arts and Manufactures for a woodcut of the "Huntsman and the Old Hound." In 1784 appeared his *Select Fables*, the engravings in which, though far surpassed by his later productions, were incomparably superior to anything that had yet been done in that line. The *Quadrupeds* appeared in 1790, and his great achievement, that with which his name is inseparably associated, the *British Birds*, was published from 1797–1804. Bewick, from his intimate knowledge of the habits of animals acquired during his constant excursions into the country, was thoroughly qualified to do justice to his great task. Of his other productions the engravings for Goldsmith's *Traveller* and *Deserted Village*, for Parnell's *Hermit*, for Somerville's *Chase*, and for the collection of *Fables of Æsop and others*, may be specially mentioned. Bewick was for many years in partnership with his former master, and in later life had numerous pupils, several of whom gained distinction as engravers. He died on the 8th November 1828. His autobiography (*Memoirs of Thomas Bewick, by Himself*, 8vo, London) appeared in 1862.

BEYLE, MARIE-HENRI, better known as De Stendhal, the most celebrated of his many *noms de plume*, was born at Grenoble on the 23d January 1783. His father was an *avocat* at the parliament of Grenoble, and his family, though not noble, was of good descent. His early education was conducted mainly by priests, who seem to have misunderstood his very peculiar character, and for whom he ever afterwards entertained a profound aversion and contempt. At the age of twelve he was sent to the École Centrale, newly established at Grenoble, and continued in attendance for four years, during which time he distinguished himself in all his studies. In 1799 he was preparing to become a candidate for the École Polytechnique when his plans were disturbed by an offer from M. Daru, a distant relative, of some appointment connected with the ministry for war. In the following year he accompanied M. Daru to Milan, on the chance of some suitable post offering itself. He was present at the battle of Marengo; and carried away, apparently, by the military enthusiasm consequent on

Napoleon's brilliant victories, he suddenly enlisted as quartermaster in a dragoon regiment. In a month's time he was made sub-lieutenant, and for about a year and a half acted as aide-de-camp to General Michaud. But the routine of garrison life, to which he was soon afterwards condemned, made him heartily tired of a military career. On the conclusion of the peace of Amiens (1802) he threw up his commission, and went to reside with his family at Grenoble. From them he obtained means to take up his abode in Paris, where for some time he continued to devote himself to study and literary work. In 1805 he suddenly accepted a situation as clerk in a mercantile house at Marseilles, and remained there nearly a year,—in fact, till the actress, for whose sake he had taken this curious step, married a wealthy Russian. In the following year he again accompanied M. Daru into Germany, and was appointed to superintend the possessions of the emperor in Brunswick. Whatever German he learnt there was afterwards completely forgotten. In his official capacity as connected with the commissariat he took part in the ill-fated Russian campaign of 1812, and remained loyal to the fallen emperor. He declined to lay himself out for employment under the new régime, and retired to Milan, where he resided till 1821. His early works, chiefly on painting and music, date from this period of his life. The *Lettres écrites de Vienne sur Haydn, suivies d'une Vie de Mozart, &c.*, which appeared in 1814 under the pseudonym of Alexandre César Bombet, were mainly plagiarized from Carpani. With some slight alterations the work was reproduced in 1817 as *Vies de Haydn, Mozart, et Metastase.* In the same year he published, under various assumed names, *Histoire de la Peinture en Italie*, which contains some good but unsystematic criticism, and *Rome, Naples, et Florence en* 1817. In 1821 he was compelled to return to France, an unfounded suspicion that he was a French spy having somehow arisen at Milan. During the following nine years he resided at Paris, and gradually began to acquire his high reputation as an accomplished litterateur and man of the world. He was an admirable talker and full of anecdote, which in his opinion ought to form the staple of conversation. His fine analytic powers were displayed to full advantage in the curious work, *De l'Amour*, which he published in 1822, but the book did not find an appreciative audience. The *Vie de Rossini*, which followed, was more successful; and the pamphlet *Racine et Shakespeare* did good service for the cause of Romanticism in its struggle with the rigid classical canons of older French literature. In 1829 appeared his *Promenades dans Rome*, full of information, criticism, and original observation, but somewhat chaotic in form. He was appointed consul at Trieste in 1830, and three years later he quitted that place with the greatest joy for a similar post at Civita Vecchia. There he remained till 1841, with frequent absences, one extending from 1836 to 1839, during which he paid a short visit to London. In 1841 his health gave way, and he returned to Paris, where he died on the 22d March 1842.

Beyle, during his lifetime, was known to but a very small circle of readers; within the last twenty years, however, his popularity has greatly increased, and his many fine powers have received due recognition. It is not probable that he will ever have a very extended influence; his writings are "caviare to the general," and can only be appreciated by those qualified to take pleasure in the cynical reflections of mere egotism. For Beyle's philosophical creed, so far as he can be said to have had one, was materialism, and his ideal of humanity æsthetically refined selfishness. His strength lay in keen criticism and in acute psychological analysis, qualities which gave value to his writings on art, but debarred him from success in the department of fiction. His principal novels, *Le Rouge et le Noir*, and *La Chartreuse de Parme*, fell comparatively dead, though the latter was received with extravagant eulogy by Balzac, and has recently become more popular. His genius was too analytic to be suited for romance writings; the novels want consistency of plot and motive power in the characters. *La Chartreuse*, however, the best of them, gives an admirable picture of the involved intrigues of a small Italian court, a subject with which Beyle was specially qualified to deal. The peculiar value of all his writings consists in the amount of thinking which they excite, though it must be confessed that the subjects are frequently unworthy of the attention devoted to them. The fullest account of Beyle is that by A. A. Paton, *Henry Beyle, a Critical and Biographical Study*, 1874. See also Colomb's prefaces to *La Chartreuse* and the *Romans et Nouvelles*, Mérimée's preface to the *Correspondance Inedite*, and Sainte-Beuve's articles in the *Causeries du Lundi.*

BEYROUT, Beirout, or Bairut, the most important seaport town of Syria, on the coast of the Mediterranean, in the pashalic of Acre, 57 miles W.N.W. of Damascus. It is situated on rising ground on the northern side of the promontory of the Jebel-er-Rosheh, which forms the spacious bay of St George's, a short distance to the west of the mouth of a stream to which it gives its name—Nahr-Beirut, the ancient Magoras. The surrounding hills consist of reddish sand, interspersed with rocks, and covered with a light soil. The roadstead to the N.E. of the town is sheltered from the S.W. wind, but is exposed to the W. and the N.W. The ancient harbour is now choked up, and all that remains of the artificial erections is a pier or causeway at the N.W. extremity of the town, at which boats can discharge. It is supported on arches of unequal size, and is partly constructed of ancient marble columns, many of which still stand along its front, and are used for mooring the lesser vessels. In 1874 the authorities determined to construct a small harbour, and £10,000 was allotted for the purpose. The city proper is an irregular square, open towards the sea, and surrounded on the land sides by a substantial tower-flanked wall, built by Djezzar Pasha. At the N.W. corner are two castellated buildings, built on the rocks. The streets are wider than is usual in Syrian towns, and are paved with large stones; the houses are for the most part lofty and spacious. Formerly, there were deep channels of water flowing down the middle of the streets, but these have been removed. The suburbs of the city, which extend around it with a radius of a mile and a half, are beautifully situated, interspersed with gardens, and planted with fruit-trees. During the hot season the wealthier inhabitants remove inland to the villages of Beit-Miry, Brumanah, or Shemlin, on the lower slopes of the Lebanon. Besides the mosques, bazaars, and other native buildings with which it is provided, the city of Beyrout possesses numerous European edifices and institutions. There are six Roman Catholic convents or monasteries, with churches and schools attached, and the sisters of charity maintain an orphanage and hospital. The Prussians support a well-organized school, under the management of a Protestant sisterhood, and the American missionaries have, among other establishments, a hospital and medical school. A girls' school was begun in 1860 by Mrs Thompson, and a ragged school in 1863. A native Christian community has been for some time in existence; and in 1847 a native society of arts and sciences was established. Formerly regarded as the port of Damascus, Beyrout has now become by far the more important of the two cities. It is the seat of various consular establishments, and possesses a quarantine, a custom-house, and post-offices. It exports silk, wool, bitumen, rags, sponges, and skins, and imports European goods for a large part of Syria. In 1871 the value of the exports, which were destined chiefly for France and England, was £530,000; while that of the imports, which were mainly from England and Germany, amounted to £1,240,000. The coasting trade, carried on by small native craft, consists principally of timber, firewood, charcoal, and straw. A lighthouse, 98 feet high, was erected in 1864 on the neighbouring cape of Ras Beyrout. A carriage road was constructed by a French company about 1863, connecting Beyrout with Damascus. An English company com-

pleted in 1874 an extensive system of water-works, by which a large supply is brought from the Nahr-el-Kelb (the Dog River or Lycus), a distance of 9 miles; the aqueduct is taken at one place through a tunnel 1040 yards long, and the water is brought to two reservoirs at the entrance of the town, each of a capacity of 110,000 cubic feet; public fountains, barracks, and mosques are supplied free of charge. The population is of a various character, comprising Druses, Maronites, Greeks, Turks, Arabs, and other races or nationalities. It was greatly increased about 1860 by an immigration of Christian natives who had fled from persecution in Mount Lebanon, Hasbeya, and Damascus. Estimated at only 15,000 in 1838, the number of inhabitants had risen in 1871 to 70,000.

Beyrout is a place of great antiquity, and may perhaps be identified with the Berothah of the Phœnicians. For a time at least it was under the supremacy of Sidon. Destroyed by Trypho, the Syrian usurper, about 140 B.C., it was restored by the elder Agrippa about 41 A.D., raised to the rank of a Roman colony, and adorned with an amphitheatre and various splendid buildings. In the 3d century it became the seat of a school of jurisprudence, which long maintained its reputation, and was attended by several eminent men. During the reign of Justinian, in fact, Beyrout was the only place in the empire, except Rome and Constantinople, where law was permitted to be taught, and of the three the Syrian school, under the management of Theophilus and Dorotheus, appears to have stood highest in general estimation. But the injury inflicted on the city by an earthquake in 551 led to the removal of the school to Sidon, and not long after the building in which it had been held was totally consumed by fire. In the time of the Crusades Beyrout again rose into importance, and was captured by Baldwin I. in 1111, after a two months' siege. Early in the 17th century it became a chief seat of the Druses, who retained their possession till 1763, when it was betrayed into the hands of the Turks. In 1772 it was bombarded and plundered by a Russian fleet, and in 1840 it was nearly destroyed by the attack of the English under Admiral Stopford.

BEZA, THEODORE, or more correctly DE BÈZE, was born at Vezelai in Burgundy on the 24th July 1519. His family was of good descent, and his parents were noted for their piety and generosity. While an infant he was adopted by his uncle, Nicholas de Beza, a counsellor of the parliament of Paris, who took his nephew to live with him, and superintended his education with the greatest care. At the age of ten he was put under the tuition of Melchior Wolmar, a German, who resided at Orleans. Beza studied under him for seven years at Orleans and at Bourges, and from him received the impulse which guided his after life. Wolmar, who was an excellent scholar, belonged to the Reformed Church, and his pupil not only learned from him the principles of the Reformed faith, but acquired the habit of diligent and critical study of Scripture. After the return of Wolmar to Germany in 1535, Beza with great reluctance departed for Orleans in order to begin the study of law. His tasks lay altogether in the direction of classics and poetry, and to this period of his life must be referred the composition of many of the licentious poems, the publication of which cost him so much regret, and has brought upon him such calumny. After four years he obtained the degree of licentiate in law, and leaving Orleans, took up his abode in Paris. He was young, ardent, and poetical, of high rank, surrounded with friends, and amply supplied with funds,—for, though he was not in orders, he enjoyed the proceeds of two benefices. It was small wonder that under these circumstances he should have yielded to the temptations of Paris, and have eagerly seized the pleasures that presented themselves. But the extent of his dissipation has been enormously exaggerated; more particularly has his connection with the woman whom he afterwards married been the occasion of calumny and misrepresentation. A severe illness at last recalled to his mind the teachings of his old master Wolmar, and brought clearly before him the contrast his conduct presented to them. Immediately on his recovery, in October 1548, he retired to Geneva, publicly fulfilled his promise to marry the woman with whom he had formerly lived, and joined the Reformed Church. In the following year he was made professor of Greek at the academy of Lausanne, where he remained for ten years, communicating frequently with Calvin at Geneva. During this time he completed Clement Marot's French translation of the Psalms, and began the extended labours on the New Testament, which resulted in his famous translation and commentary. His veneration for Calvin, already great, was strengthened by closer intercourse; he vigorously defended the execution of Servetus; and in 1558 he gladly removed to Geneva. He was appointed professor of Greek in the academy, and assisted Calvin in his theological lectures. Soon by his vigorous teaching, his numerous writings, and his success in foreign embassies, he came to be looked upon as the most prominent man in the church of Geneva next to Calvin; and after the death of the latter in 1564, he was nominated his successor as teacher of theology, and generally recognized as the leader of the Calvinist party. His enormous activity enabled him not only to manage the internal affairs of the church, and to carry on the important negotiations with France and other powers, but also to compose several theological works of considerable value. Old age did not rob him of his energy; for in 1597 he was able to give a satirical refutation of the story spread about by the Roman Catholics that he had apostatized on his death-bed. He resigned all his official functions in 1600, and died on the 13th October 1605, at the advanced age of 86.

Beza's works were very numerous, and some of them, such as *Histoire ecclésiastique des églises réformées du royaume de France*, *Confessio*, *Tractationes Theologicæ*, are still of value. His reputation, however, rested, and still perhaps rests, on his editions and translations of the New Testament, which did much for the cause of the Reformation. See Schlosser, *Leben des Theodor Beza, etc.*, 1809; Baum, *Theodor Beza*, 2 vols., 1843-51 (incomplete). A biography of him was written by one of his favourite pupils, Antoine La Faye.

BÉZIERS, a city of France, in the department of Hérault, the capital of an arrondissement of the same name. It is beautifully situated on a hill, on the left bank of the River Orbe, where it is joined by the Languedoc canal, 38 miles S.W. of Montpellier. It is surrounded by old walls flanked with towers, round which is a promenade planted with trees, and has a fine old Gothic cathedral, Saint Nazaire, dating from the 12th, 13th, and 14th centuries, several churches, an old episcopal palace, now used for the Government offices, a communal college, an agricultural society, a theatre, and a public library. It manufactures silk stockings, starch, gloves, brandy, confectionery, paper, leather, and glass, and has a considerable trade. Béziers is of great antiquity, and has the remains of an amphitheatre, a causeway across the marsh of Cap-estang, and other Roman works. The Romans established a colony there, and it was the headquarters of the seventh legion, under the title of *Bœterra Septimanorum*. The present name occurs in the form *Besara* as early as Festus Avienus (5th or 6th century). The town was completely destroyed in 1209 by the forces of Simon de Montfort in the crusade against the Albigenses, on which occasion 60,000 persons were massacred. The walls of the town were rebuilt in 1289; but it again suffered severely in the civil and religious wars of the 16th century, and all its fortifications were destroyed in 1632. Population in 1872, 30,067

BÉZIQUE, a game at cards (probably from Sp. *besico*, little kiss, in allusion to the meeting of the queen and knave, an important feature in the game). There is a group of card games which possess many features in common. The oldest of these is *mariage*, then follow *brusquembille*, *l'homme de brou*, *briscan* or *brisque*, and *cinq-cents*.

Bézique (also called *besi* and *besigue*) appears to have been founded on these; it is, in fact, *brisque* played with a double pack, and with certain modifications rendered necessary by the introduction of additional cards.

In playing bézique, two packs of cards from which the twos, threes, fours, fives, and sixes have been rejected, are shuffled together and used as one. The packs should have backs similarly coloured or ornamented.

The players cut for deal, and the highest bézique card deals. The cards rank as follows:—Ace, ten, king, queen, knave, nine, eight, seven.

The non-dealer cuts the pack to the dealer, who reunites the separated packets, and deals three cards to his adversary, three to himself, then two to each, and again three to each. The top card of those remaining (called the *stock*) is turned up for trumps. The stock is placed face downwards between the players, and slightly spread. The players then take up the cards dealt to them, and the non-dealer plays any card out of his hand, and the dealer plays a card to it from his hand, the two cards thus played constituting a *trick*. There is no restriction as to the card to be played; the second player need not follow suit, nor win the trick. If he wins the trick by playing a higher card of the suit led, or a trump, the lead falls to him. In case of ties the leader wins. Whoever wins the trick leads to the next; but before playing again each player takes a card from the stock, and adds it to his hand, the winner of the trick taking the top card of those face downwards, and his adversary the next card. This alternate playing and drawing a card each continues until the stock (including the trump card or card exchanged for it, which is taken up last) is exhausted. The tricks remain face upwards on the table, but must not be searched during the play of the hand.

The objects of the play are—1. To promote in the hand various combinations of cards, which when *declared* entitle the holder to certain scores; 2. To win aces and tens; 3. To win the so-called last trick.

A declaration can only be made by the winner of a trick immediately after he has won it, and before he draws from the stock. It is effected by placing the declared cards (one of which at least must not have been declared before) face upwards on the table. Declared cards are left face up on the table; but they still form part of the hand, and can be led or played just as though they had not been declared. A player is not bound to declare, although he may win a trick and hold scoring cards. A card led or played cannot be declared. More than one declaration may be made to one trick, provided no card of one combination forms part of another that is declared with it. Thus four knaves and a marriage (see table of scores) may be declared at the same time; but a player cannot declare king and queen of spades and knave of diamonds together to score marriage and bézique with those three cards. He must first declare one combination, say bézique; and when he wins another trick he can score marriage by declaring the king. A declaration cannot be made of cards that have already all been declared. Thus, if four knaves (one being a bézique knave) and four queens (one being a bézique queen) have been declared, the knave and queen already declared cannot be declared again as bézique. To score all the combinations with these cards, after the knaves are declared and another trick won, bézique must next be made, after which, on winning another trick, the three queens can be added, and four queens scored. Again, if a sequence in trumps is declared, marriage of the king and queen on the table cannot afterwards take place. To score both, the marriage should be declared first, and after winning another trick the remaining sequence cards should be added. Lastly, a card once declared can only be used again in declaring in combinations of a different class. For example: the bézique queen can be declared in bézique, marriage, and four queens; but having once been declared in single bézique, she cannot form part of another single bézique; having been married once, she cannot be married again; and having taken part in one set of four queens, she cannot take part in another.

The seven of trumps may be either declared or exchanged for the turn-up after winning a trick, and before drawing. When exchanged, the turn-up is taken into the player's hand, and the seven put in its place. The second seven is, of course, declared, as it would be absurd to exchange one seven for another. A seven when declared is not left on the table, but is simply shown.

Table of Bézique Scores.

Seven of trumps,[1] turned up, dealer marks	10
Seven of trumps, declared or exchanged, player marks	10
Marriage (king and queen of any suit) declared	20
Royal marriage (king and queen of trumps) declared	40
Bézique[2] **(queen of spades and knave of diamonds) declared**	**40**
Double bézique[3] (all the four bézique cards) declared	500
Four aces (any four, whether duplicates or not), declared	100
Four kings (any four) declared	80
Four queens (any four) declared	60
Four knaves (any four) declared	40
Sequence (ace, ten, king, queen, knave of trumps) declared	150 250
Aces and tens,[4] in tricks, the winner for each one marks	10
Last trick,[5] the winner marks	10

The winner of the last trick can declare anything in his hand (subject to the limitations with regard to declaring already explained). After this all declarations cease. The winner of the last trick takes the last card of the stock, and the loser the turn up card (or seven exchanged for it). All cards on the table, that have been declared and not played, are taken up by their owners. The last eight tricks are then played, but the rules of play alter. The winner of the last trick leads. The second player must follow suit if able, and must win the trick if able, and if not able to follow suit, he must win the trick if he can by trumping. The winner of the trick leads to the next. The tricks are only valuable for the aces and tens they may contain. If a player revokes in the last eight tricks, or does not win the card led, if able, the last eight tricks belong to his adversary.

When a deal is over, the non-dealer in the previous hand deals, and so on alternately until the game is won by one of the players reaching 1000. All the scores are reckoned by tens, but there is no reason why they should not be reckoned by units, the game in that case being 100 up. The score may be kept by means of a bézique board and pegs, or by a numbered dial and hand, or by counters.

PENALTIES.—If the dealer gives too few cards the number must be completed from the stock, or the non-dealer, not having looked at his cards, may have a fresh deal.

If the dealer gives his adversary too many cards the player who has too many must not draw until his number is reduced to seven.

If the dealer gives himself too many cards the non-dealer may draw the surplus cards and add them to the stock, unless the dealer has looked at his hand, when he is liable to the penalty for playing with nine cards (*infra*).

A card exposed in dealing gives the adversary the option of a fresh deal.

If a player draws out of his turn, and the adversary discovers the error before he draws, he may add 20 to his score, or deduct 20 from his adversary's.

If the winner of a trick when drawing lifts two cards, the adversary may have them exposed, and take his choice. If the loser of a trick lifts two cards, the adversary may look at the one improperly lifted, and at the next draw that card and the next are turned face up, and the player not in fault has his choice of them.

If a player plays with seven cards his adversary may add 20 to his own score, or deduct 20 from the offender's. The player with a card short must take two cards at his next draw.

If at any time during the play of the hand one player is found to hold nine cards, the other having but eight, the adversary of the player with nine cards may add 200 to his own score, or deduct 200 from the offender's. The player with nine cards must play to the next trick without drawing.

There is no penalty at two handed bézique for exposing a card from the hand, or for leading out of turn. At three or four handed bézique, a card exposed or led out of turn must remain on the table, and nothing can be subsequently declared in combination with it.

[1] Some players do not turn up a card for trumps, but make the trump suit depend on the first marriage declared. The turning up rule is the best

[2] When clubs or hearts are trumps, the bézique cards are queen of spades and knave of diamonds. When spades or diamonds are trumps, the bézique cards are queen of clubs and knave of hearts. Some players object to this alteration, but it is a great improvement to the game.

[3] If single bézique is declared first, and then the two other bézique cards added, 500 is scored in addition to the 40 already scored; but if all four are declared together only 500 can be scored, and not 540.

[4] The winner of a trick containing two aces or two tens, or one of each, of course marks 20. The best plan is to score aces and tens immediately they are won; but some players only score them at the end of the hand. When this mode is adopted, the winner of a trick containing an ace or ten takes the tricks on the table and turns them face downwards in front of himself, and after the hand is over looks through his packet to ascertain the number of aces and tens it contains. When scoring in this way it occasionally happens that both players can score out, in which case precedence is given to the winner of the so-called last trick.

[5] The so-called last trick is the last before the stock is exhausted. When two cards of the stock, viz., the trump and another card, remain on the table, the player winning the trick is said to win the *last* trick, notwithstanding that there are still eight tricks to be played.

When a card is led out of turn, if all the other players play to it, the error cannot be rectified.

Three and Four Handed Bézique.—*When three play*, three packs are used together. All play against each other. The dealer deals to his left; the player first dealt to has the first lead. The rotation of dealing goes to the left. A second double bézique, counting 500, may be declared to a bézique on the table, which has already been used for double bézique. Triple bézique scores 1500. All the cards of the triple bézique must be on the table at the same time and unplayed to a trick. All may be declared together, or a double bézique may be added to a single one, or a third bézique may be added to a double bézique already declared. The game is 2000 up. In playing the last eight tricks, the third hand, if not able to follow suit, nor to win the trick by trumping, may throw away any card he pleases.

When four play, four packs are shuffled together and used as one. The players may score independently, or they may play as partners. A second double bézique or triple bézique may be scored as before; to form them the béziques may be declared from the hand of either partner. A player may declare when he or his partner takes a trick. In playing the last eight tricks, the winner of the last trick and the adversary to his left play their cards against each other, and then the other two similarly play theirs.

Hints to Players.—The following hints, which merely touch on the elements of the play, may assist the beginner:—

The lead is, as a rule, disadvantageous. Therefore do not win the trick unless—(1) you want to declare; or (2) you wish to make an ace or ten of the suit led; or (3) an ace or a ten is led which you desire to win.

Sevens, eights, and nines in plain suits are valueless. In trumps they should be kept to obtain the lead with. It is very important to keep one small trump in hand if possible. Knaves also are of but little value (except bézique and trump knaves), and may be thrown away freely.

It is of more importance to win aces and tens or to make tricks with them than at first sight appears. Experienced players prefer a number of small scores to sacrificing them for the chance of a large one. Therefore it is not considered good play as a rule to go for four aces unless you have three, and are in no difficulty as to your play. Rather make tricks with the aces, and especially capture tens with them. Whenever you are second player, and can win a trick with a ten, take it, except in trumps, of which the ten is kept for sequence.

When in difficulties, lead an ace or a ten in preference to a king or queen. As a rule, if you try for aces, you have to sacrifice some other score, and are pretty sure to lose some of the aces after declaring them.

If driven to lead an ace or a ten, and your opponent does not win it, lead another.

Endeavour to recollect in what suits the aces and tens have been played, so that, when leading, you may choose suits of which the most aces and tens are out. Similarly, if your adversary declares aces, avoid leading the suits of the declared aces; and, in discarding, retain those cards which are least likely to be taken by aces and tens.

Having a choice between playing a possible scoring card, or a small trump, or a card that you have declared, generally play the last so as to conceal your hand.

Do not part with a sequence card early in the hand, even if you have a duplicate, as playing it shows that you are likely to hold the duplicate, and you thus free your opponent's game, as he will immediately use his trump sequence cards to win all the aces and tens you lead.

Also, do not part with bézique cards until near the end of the hand, even after declaring bézique, because by so doing you give up all chance of double bézique. If you draw or hold a third bézique card, sacrifice everything, even sequence cards, for the chance of a double bézique.

Avoid declaring combinations which show your adversary that he cannot make sequence or double bézique. By keeping him in the dark you hamper his game, and are very likely to cause him to refrain from trumping your aces or tens. For example, if early in the hand you hold two trump queens and two bézique queens, you should postpone declaring them as long as possible, or even sacrifice the score altogether.

You may often judge during the play of the hand what combinations your adversary is going for. Thus, if he discards kings he is probably strong in queens, and *vice versa*. If in doubt as to whether you should keep kings or queens, you of course choose the combination he is not trying for. With attention and experience it is surprising how much may be inferred as to your adversary's game, and how greatly your own line of play may be thus directed.

It is as a rule right to win the last trick, in order to prevent the adversary from declaring, for which purpose lead the ace of trumps. When within a few tricks of the end of the hand, you may often prevent your opponent from scoring sequence by leading out your high trumps.

In playing the last eight tricks your object is simply to make as many aces and tens as you can, and to win those of your adversary.

Polish Bézique (also called *Open Bézique* and *Fildniski*) differs from ordinary bézique in the following particulars:—

Whenever a scoring card is played, the winner of the trick places it face upwards in front of him (the same with both cards if two scoring cards are played to a trick), forming rows of aces, kings, queens, knaves, and trump tens (called *open* cards). Cards of the same denomination are placed overlapping one another lengthwise from the player towards his adversary to economise space. When a scoring card is placed among the open cards, all the sevens, eights, nines, and plain suit tens in the tricks are turned down. Open cards cannot be played a second time, and can only be used in declaring. Whether so used or not they remain face upwards on the table until the end of the hand, including the last eight tricks. A player can declare after winning a trick and before drawing again, when the trick won contains a card or cards, which added to his open cards complete any combination that scores. Every declaration must include a card played to the trick last won. Aces and tens must be scored as soon as won, and not at the end of the hand. The seven of trumps can be exchanged by the winner of the trick containing it; and if the turn-up card is one that can be used in declaring, it becomes an open card when exchanged. The seven of trumps when not exchanged is scored for by the player winning the trick containing it.

Compound declarations are allowed, *i.e.*, cards added to the open cards can at once be used, without waiting to win another trick, in as many combinations of different classes as they will form with the winner's open cards. For example: A has three open kings, and he wins a trick containing a king. Before drawing again he places the fourth king with the other three, and scores 80 for kings. This is a simple declaration. But suppose the card led was the queen of trumps, and A wins it with the king, and he has the following open cards—three kings, three queens, and ace, ten, knave of trumps. He at once declares royal marriage (40); four kings (80); four queens (60); and sequence (250); and scores in all, 430. Again: ace of spades is turned up, and ace of hearts is led. The second player has two open aces, and wins the ace of hearts with the seven of trumps and exchanges. He scores for the exchange, 10; for the ace of hearts, 10; for the ace of spades, 10; and adds the aces to his open cards, and scores 100 for aces; in all, 130. If a declaration or part of a compound declaration is omitted, and the winner of the trick draws again, he cannot amend his score.

The ordinary rule holds that a second declaration cannot be made of a card already declared in the same class. Thus: a queen once married cannot be married again; a fifth king added to four already declared does not entitle to another score for kings.

The fundamental point to be borne in mind is, that no declaration can be effected by means of cards held in the hand. Thus: A having three open queens and a queen in hand cannot add it to his open cards. He must win another trick containing a queen, when he can declare queens.

Declarations continue during the play of the last eight tricks just the same as during the play of the other cards.

The game is 2000 up. After each deal it is advisable to shuffle thoroughly; otherwise a number of small cards will run together in the stock, and impair the interest of the game. It is also advisable to adopt the change in the bézique cards recommended for ordinary bézique, otherwise the scores of one hand may run very high, and of the other very low, which spoils the game. The lead is even more disadvantageous than at ordinary bézique. It is important not to lead cards that can be won by bézique cards. It is often advisable to win with a high card though able to win with a low one; thus having king, nine of a suit of which the eight is led, if you win the trick, you should take it with the king. It is not of so much consequence to win aces and tens (especially the latter) as at ordinary bézique. It is a difficult point in the game to decide whether to win tricks with sequence cards, on the chance of eventually scoring sequence, or to reserve trumps for the last eight tricks. As a rule, if the hand is well advanced, and you are badly off in trumps, win tricks with sequence cards, and especially if you have duplicate sequence cards make them both. If badly off in trumps towards the end of a hand, and your adversary may win double bézique, keep in hand an ace or ten of the bézique suits, as when it comes to the last eight tricks (in which suit must be followed), you may prevent the score of double bézique.

Grand Bézique (also called *Chinese Bézique*) is played like ordinary bézique, except as follows:—

Four packs are shuffled together and used as one, and nine cards are dealt to each player, by three at a time to each. When a combination is declared, and one of the cards composing it is played away, another declaration can be completed (after winning a trick) with the same cards. Thus: A declares four aces, and uses one to win a trick, or throws one away. A has a fifth ace in hand and wins a

trick, he can add it to the three remaining declared aces, and score four aces again, and so on. Marriages can be declared over and over again; thus king, queen of hearts are declared, and the player draws another king of hearts. He plays the declared king and wins the trick, he can then marry the queen again. Some players object to this, calling it bigamy; but if only permitted after the declared king is played, it is not bigamy, but the marriage of a widow. Bézique follows the same rule: if, say, the knave is played away, another knave makes another bézique; and so on with double and triple bézique, if the former declared cards which remain unplayed can be matched from cards in hand to make the requisite combinations. Sequence can be declared over and over again, and compound declarations made among the declared cards are now generally allowed. The sevens of trumps do not count, nor does the last trick, or at all events these only count by agreement. The game is 3000 up. The great points to aim at are to declare four aces or sequence, which can then be declared over and over again, if fresh aces or sequence cards are taken into hand (the duplicate sequence cards being first played away). With fair chance of sequence everything else, even aces or chance of double bézique, should be sacrificed. (H. J.)

BHÁGALPUR, a division or commissionership of British India, under the Lieutenant-Governor of Bengal, comprising the districts of Bhágalpur, Monghir, Santál Parganás, and Purniah, lies between 23° and 27° N. lat., and 85° and 89° E. long. It is bounded on the N. by the independent state of Nepál and the British district of Dárjiling; on the E. by the districts of Jalpáiguri, Dinájpur, Máldah, Murshidábád, and Bírbhúm; on the S. by the districts of Bírbhúm, Mánbhúm, and Hazáríbágh; and on the W. by the districts of Gayá, Patná, and Tirhut. According to the census report of 1872, Bhágalpur division contained an area of 18,685 square miles, with a total population, of 6,613,358 (*i.e.*, 354 to the square mile), inhabiting 19,247 villages and 1,801,497 houses. Of this population 4,925,714, or 74·5 per cent., are Hindus; 1,121,630, or 17·0 per cent., Mahometans; 2469 Christians; 53 Buddhists; 563,492, or 8·5 per cent., of unspecified religion, chiefly consisting of aboriginal tribes.

BHÁGALPUR, a district of British India in the division of the same name, under the Lieutenant-Governor of Bengal, situated between 26° 35′ 30″ and 24° 32′ 39″ N. lat., and 87° 33′ 51″ and 86° 21′ 32″ E. long. It is bounded on the N. by the independent state of Nepál, on the E. by the districts of Purniah and the Santál Parganás, on the S. by the Santál Parganás and Hazáríbágh, and on the W. by the districts of Monghir and Tirhut. Bhágalpur is a long and narrow district, divided into two unequal parts by the River Ganges. In the southern portion of the district the scenery in parts of the hill-ranges and the highlands which connect them is very beautiful. The hills are of the primary formation, with fine masses of contorted gneiss. The ground is broken up into picturesque gorges and deep ravines, and the whole is covered with fine forest trees and a rich undergrowth. Within this portion also lie the lowlands of Bhágalpur, fertile, well planted, well watered, and highly cultivated. The country north of the Ganges is level, but beautifully diversified with trees and verdure. Three fine rivers flow through the district—the Ganges, Kusí, and Ghagrí. The Ganges runs a course of 60 miles through Bhágalpur, is navigable all the year round, and has an average width of three miles. The Kusí rises in the Himálayas and falls into the Ganges near Colgong (Kahlgáon), within Bhágalpur. It is a fine stream, navigable up to the foot of the hills, and receives the Ghagrí eight miles above its debouchure.

The census of 1872 disclosed a population of 1,826,290 souls, inhabiting 2739 towns or villages; and 329,372 houses, giving an average of 422 per square mile, 667 per village, and 5·5 per house. Of the total population, 1,639,949, or 89·8 per cent., are Hindus; 169,426, or 9·3 per cent., Mahometans; 532 Christians; 19 Buddhists; 16,364, or ·9 per cent., of unspecified religions, chiefly of aboriginal tribes, consisting of hillmen, Náts, Santáls, &c. In the early days of British administration these hill people gave much trouble. They were the original inhabitants of the country whom the Aryan conquerors had driven back into the barren hills and unhealthy forests. This they avenged from generation to generation by plundering and ravaging the plains. The efforts to subdue or restrain these marauders proved fruitless, till Augustus Cleveland, the collector of Bhágalpur in the latter half of last century, won them by mild measures, and successfully made over the protection of the district to the very hill people who a few years before had been its scourge. Rice, wheat, barley, oats, Indian corn, various kinds of millet, pulses, oil-seeds, tobacco, cotton, indigo, opium, flax and hemp, and sugar-cane, are the principal agricultural products of Bhágalpur district. The jungles afford good pasturage in the hot weather, and abound in lac, silk cocoons, catechu, resin, and the *mahud* fruit, which is both used as fruit and for the manufacture of spirits. Iron, gold, coal, and building stone are found, but no iron or coal is at present smelted or worked. Gold is washed from the river sand in small particles. Silk cloth, called *tasar*, and pots similar to Chinese ware, are the principal manufactures of Bhágalpur. Principal seats of trade—Bhágalpur, Ghoghá, Colgong (Kahlgáon), Pírpaintí, and Sultánganj on the East Indian Railway; Umarpur, Purainí, Chándpur, Belhar, Jaipur, Katariá, Sabalpur, Panjwárá, and Chandan, in the south of the district; and Bihpur, Krishnaganj, Muralíganj, and Pratápganj north of the Ganges. Besides nine principal roads with a total length of 368 miles, which form the means of external and internal communication, 62 miles of the East Indian Railway connect Bhágalpur with Calcutta and Upper India. For administrative purposes Bhágalpur district is divided into four magisterial subdivisions, viz., the headquarters subdivision, and those of Bánkí, Madhupurá, and Supul; and for police purposes into twelve *thánás*. A regular police, 600 strong, was maintained in 1872 at a total cost of £9569, or an average of one man to every 7·06 square miles, and 2979 of the population. Besides the regular police there were, in 1872, 3666 village watchmen, supported at an estimated cost of £5700, paid by the landholders and villagers, exclusive of the service lands which they enjoy rent free. The total net revenue of the district, in 1870-71, amounted to £139,545, of which £72,161, or 51·71 per cent., was derived from the land; expenditure, £82,570. For the education of the people there were, in 1872, 14 Government and aided schools, attended by 876 pupils, and maintained at a total cost of £2813, of which Government contributed £929. The unaided schools numbered 314, attended by 3593 pupils. The climate of Bhágalpur partakes of the character both of the deltaic districts of Bengal and of the districts of Behar, between which it is situated. The hot season sets in about the end of March, continues till the beginning of June, the temperature at this time rising as high as 110° Fahr. The rains usually begin at the end of June and last till the middle of September; average annual rainfall, 55 inches. The cold season commences at the beginning of November and lasts till March. During December and January the temperature falls as low as 41° Fahr. The average annual temperature is 78°. Bhágalpur formed a part of the ancient Sanskrit kingdom of Anga. In later times it was included in the powerful Hindu kingdom of Magadha or Behar, and in the 7th century A.D. it was an independent state, with the city of Champá for its capital. It afterwards formed a part of the Mahometan kingdom of Gaur, and was subsequently subjugated by Akbar, who declared it to be a part of the Delhi empire. Bhágalpur passed to the East India Company by the grant of the Emperor Sháh Alam in 1765. (W. W. H.)

BHÁGALPUR, the principal town of the district and division of the same name, situated on the right bank of the Ganges, here seven miles wide, in 25° 11′ N. lat. and 87° E. long. The town is two miles in length and a mile in width, but lies in a low, open valley, and consists of scattered market-places meanly built. Its most interesting objects are two ancient round towers, each about 70 feet high. Adjacent to the town are the two Cleveland monuments, one erected by Government, and the other by the Hindus, to the memory of the civilian, who, at the end of last century, "by conciliation, confidence, and benevolence, attempted and accomplished the entire subjection of the lawless and savage inhabitants of the Jungleterry of Rájmahal." Bhágalpur is the headquarters of the commissioner of the division and of the judge and collector of the district; it is also a station of the East Indian Railway. Its Government school was attended by 361 pupils in 1872. In the same year the town contained a population of 69,678 souls, of whom 50,673, or 72 per cent., are Hindus; 18,455, or 26 per cent., Mahometans; 19 were Buddhists, 342 Christians, and 189 unclassified. Municipal income, in 1872, £2951, 6s.; expenditure, £3470, 14s.; incidence of municipal taxation, 10½d. per head of the town population.

BHAMÔ, or Banmo (in Chinese, Tsinggai), a city of Upper Burmah, situated in 24° 16′ N. lat. and 95° 54′ 47″ E. long., on the left bank of the Irawady, a short distance below its confluence with the Tapeng, and about 300 miles up the river from Mandalay the capital. It was formerly a very flourishing city, and the chief town of a Shan principality; and though greatly decayed, it is still the seat of a Burmese governor and the centre of a considerable trade. At the time of Dr John Anderson's visit in the year 1868 (*Expedition to Western Yunnan*, 1871), it consisted of about 500 houses of sun-burnt brick, and had an estimated population of 2500, partly Shans and partly Chinese. The latter possess a temple and theatre, and there were remains of ancient pagodas and other buildings. In the neighbourhood are ruins of two cities, called Tsampenago, both of considerable extent. Special attention has been directed to Bhamô as an important position for the development of commerce between British India and Western Yunnan, no fewer than four practical routes leading eastward from the city to Momein.

BHANDÁRÁ, a district of British India, under the jurisdiction of the Chief Commissioner of the Central Provinces, situated between 20° and 22° N. lat., and 79° and 81° E. long. It is bounded on the N. by the districts of Seoní and Bálághát, on the E. by the district of Ráipur, on the S. by the district of Chándá, and on the W. by the district of Nágpur. To the north, north-east, and east, a natural boundary line is marked out by lofty hills, inhabited by Gonds and other aboriginal tribes, while the west and north-west are comparatively open. Small branches of the Sátpurá range make their way into the interior of the district. The Ambagarh, or Sendurjharí hills, which skirt the south of the Chandpur parganá, have an average height of between 300 and 400 feet above the level of the plain. The other elevated tracts are the Baláhí hills, the Kanherí hills, and the Nawegáon hills. The Wainganga is the principal river in the district, and the only stream that does not dry up in the hot weather,—its affluents within the district being the Báwantharí, Bághnadí, Kanhán, and Chulban. There are 3648 small lakes and tanks in Bhandárá district, whence it is called the "lake region of Nágpur;" they afford ample means of irrigation. More than one-third of the district lies under jungle, which yields gum, medicinal fruits and nuts, edible fruits, lac, honey, and the blossoms of the *mahuá* tree (*Bassia latifolia*), which are eaten by the poorer classes, and used for the manufacture of a kind of spirit. Tigers, panthers, deer, wild hogs, and other wild animals abound in the forests, and during the rainy season many deaths occur from snake-bites.

Bhandárá district contains an assessed area of 3148·61 square miles, or 2,015,114 acres, of which 819,922 acres were under cultivation in 1869; 30,845 acres, grazing lands; 550,922 acres, cultivable but not under cultivation; and 613,425 acres uncultivable waste. The census of 1872 gave the total area of the district at 3922 square miles, and returned the population at 564,819 (144 to the square mile), residing in 106,121 houses and 1589 villages. Of the total population, 472,151, or 83·60 per cent., were Hindus; 10,696, or 1·89 per cent., Mahometans; 520 Buddhists or Jains; 61 Christians; and 81,379, or 14·41 per cent., were aboriginal tribes of unspecified religion. The Hindu population is chiefly divided into the following castes:—Bráhmans, "Pardesís," or foreigners (generally Rájputs), Ponwárs, Lodhís, Kunbís, Korís, Kaláls, Telís, Dhímars, Koshtís, Goárás, and Dhers. The inhabitants are rude and unpolished in their manners, and slothful in their habits. The agricultural products of the district consist of rice, wheat, grain, pulses, peas, sugar-cane, oil-seeds, and cotton; the following being an estimate of the acreage under different crops:—rice, 543,019 acres; wheat, 86,064; other food grains, 147,982; oil-seeds, 27,068; sugar-cane, 12,561; fibres, 197; tobacco, 558; and vegetables, 2128 acres—total, 819,477 acres, or 1280·43 square miles. Iron is the chief mineral product. Gold is also found in the bed of the Son Nadí, but does not repay the trouble of searching for it. Laterite, shale, and sandstone occur all over the district—the largest quarries being near Bhandárá town, at Korambí, and in the Baláhí hills. Native cloth, brass wares, pot-stone wares, cart-wheels, straw and reed baskets, and a small quantity of silk, form the only manufactures of the district. Cotton, salt, wheat, rice, oil-seeds, hardware, English piece goods, tobacco, silk, dyes, and cattle, are its chief articles of import; and country cloth, tobacco, and hardware its exports. The Great Eastern Road is the only well-raised, bridged, and metalled road in the district; but there are also five or six second-class roads, unmetalled and unbridged, but levelled, and sloped at the crossings of water-courses. The revenue demand for 1868–69 amounted to £40,296, 8s. from land, £5592, 2s. from excise, £3774, 18s. from stamps, £2553, 10s. from forests, £5051, 10s. from assessed taxes—total, £57,268, 8s. The regular police force of 442 men was maintained in 1868 at a cost of £5584, 10s., exclusive of the village watch. In 1868 the district contained 38 Government and 78 private schools, affording instruction to 7109 boys and 215 girls. Four towns have upwards of 5000 inhabitants: (1.) Bhandárá—population, 11,433; municipal income, £486; expenditure, £645, 6s.; rate of taxation, 10¼d. per head; (2.) Tumsar—population, 7367; municipal income, £1305; expenditure, £554, 10s.; rate of taxation, 3s. 6½d. per head; (3.) Mohárí—population, 6183; municipal revenue, £198; expenditure, £244, 2s.; rate of taxation, 7⅝d. per head; (4.) Pauní—population, 8976; municipal revenue, £174, 10s.; expenditure, £233, 18s.; rate of taxation, 4⅝d. per head. Bhandárá district contains 25 semi-independent chiefships, having an area of 1509 square miles, and a population of 166,005 souls in 1866. These little states are exempted from the revenue system, and only pay a light tribute. Their territory, however, is included within the returns of area and population above given. The climate of Bhandárá is unhealthy,—the prevailing diseases being fever, small-pox, and cholera. Nothing is known of the early history of the district. Tradition says that at a remote period a tribe of men, called the Gaulís or Gaulars, overran and conquered it. At the end of the 17th century it belonged to the Gond Rájá of Deogarh. In 1738 it was conquered by the Marhattás, who governed it till the year 1854, when it lapsed to the British Government, the Rájá of Nágpur having died without an heir.

Bhandárá, the principal town and headquarters of the district of the same name, is situated on the Waingangá, about 38 miles east of Nágpur. The town is kept neat and clean, is well drained, and is considered healthy. In 1872 it contained a total population of 11,433 souls, of whom 9657 were Hindus, 1450 Mahometans, 58 Buddhists and Jains, 54 Christians, and 214 of unspecified religion. For income, &c., see above. The town enjoys a considerable trade in cotton cloth and the local hardware.

BHANG, an East Indian name for the hemp plant, *Cannabis sativa*, but applied specially to the leaves dried and prepared for use as a narcotic drug. The hemp plant, as cultivated in the Bengal Presidency and the North-West Provinces, yields a peculiar resinous exudation, which is altogether wanting in the hemp grown on account of its fibre in European countries. For this resinous exudation, in which its virtues as a drug reside, hemp is cultivated in Kashmir, Bokhára, Yarkand, and Central Asia generally, besides North India, and in certain parts of East Africa, where, according to Captain Burton, it is grown "before every cottage door." In India the products of the plant for use as a narcotic and intoxicant are recognized under the three names and forms of Bhang, Gunja or Ganja, and Churrus or Charas. Bhang consists of the larger leaves and capsules of the plant on which an efflorescence of resinous matter has occurred. The leaves are in broken and partly agglutinated pieces, having a dark-green colour and a heavy but not unpleasant smell. Bhang is used in India for smoking, with or without tobacco; it is prepared in the form of a cake or manjan, and it is made into an intoxicating beverage by infusing in cold water and straining. Gunja is the flowering or fruit-bearing tops of the female plants. It is gathered in stalks of several inches in length, the tops of which form a matted mass, from the agglutination of flowers, seeds, and leaflets by the abundant resinous exudation which coats them. Churrus is the resinous substance separated from the plant. According to Dr O'Shaughnessy it is obtained by men dressed in leathern aprons brushing forcibly through the growing stalks, and the resin which thereby adheres to the leather is scraped off with knives. It is stated that in Nepal the

leather covering is dispensed with, and the resin gathered on the naked bodies of coolies, who brush through the standing stalks. Dr Royle says, "the glandular secretion is collected from the plants on the hills by the natives pressing the upper part of the young plants between the palms of their hands, and scraping off the secretion which adheres." The preparation known as hashish among the Arabs is similar to the gunja of India, and is used in the same manner. The use of preparations of hemp among the Mussulman and Hindu population of India is very general; and the habit also obtains among the population of Central Asia, the Arabs, and Egyptians, extending even to the negroes of the valley of the Zambesi and the Hottentots of South Africa. The habit appears to date from very remote times, for Herodotus says of the Scythians, that they creep inside huts and throw hemp seeds on hot stones. The seeds "soon send forth a virulent intoxicating smoke, which fills the close tent, and the people inside, being overpowered with the intoxicating effects, howl with excitement and delight." The observations of Dr O'Shaughnessy on the effects of the drug on the native population of India led him to conclude that it alleviates pain, and causes a remarkable increase of appetite, unequivocal aphrodisia, and great mental cheerfulness. Its violent effects are delirium of a peculiar kind, and the production of a cataleptic condition. Sir Robert Christison says, that "for energy, certainty, and convenience, Indian hemp is the next anodyne, hypnotic, and antispasmodic to opium and its derivatives, and often equal to it." Preparations are used in British pharmacy in the form of tincture and extract prepared from gunja, and it is understood to form an ingredient in the patent medicine chlorodyne.

BHARÁICH, a district of British India, under the jurisdiction of the Chief Commissioner of Oudh, situated between 28° 23′ and 27° 4′ N. lat., and 82° 11′ and 81° 9′ E. long. It is bounded on the N. by the independent state of Nepál, on the E. and S.E. by the district of Gondá, on the S.W. by the district of Bára Bánki, and on the W. by the districts of Sítápur and Kherí. Bharáich district consists of three tracts:—(1), in the centre, an elevated triangular plateau, projecting from the base of the Himálayas for about 50 miles in a south-easterly direction—average breadth 13 miles, area 670 square miles; (2), the great plain of the Ghagrá, on the west, about 40 feet below the level of the plateau; and (3), on the east, another lesser area of depression. The *Tarái*, or the forest and marshy tracts along the southern slopes of the Himálayas, gradually merge within the district into drier land, the beds of the streams become deeper and more marked, the marshes disappear, and the country assumes the ordinary appearance of the plain of the Ganges. The Ghagrá skirts the district for 114 miles; and the Raptí, with its branch the Bhaklá, drains the high grounds.

District area, 2398 square miles, since the redistribution of territory in 1869; prior to this its area was 2682 square miles. In 1872 the district contained a total population of 774,640 souls, residing in 121,905 houses and 1965 villages; of which 676,313 were Hindus, 98,124 Mahometans, and 40 Christians, and the rest of unclassified religions. Of the Hindu population the Bráhmans number 71,215; Kshatriyas, 20,514; Ahírs, 91,479; Chámárs, 56,329; Kurmís, 79,723. Principal crops and estimated acreage:—rice, 167,000 acres; Indian corn, 76,000; wheat, 73,000; barley, 84,000; and rape-seed, 25,000 acres. Besides these, other kinds of oil-seeds, pulses, sugar, cotton, opium, indigo, fibres, tobacco, and vegetables are also cultivated. Total assessed area of the district, 1,348,104 acres; of which 836,441 are under cultivation, 511,663 cultivable grazing land, and 187,247 uncultivable waste. Land tax, £114,507; rate per cultivated acre, 2s. 9d. Of the population 495,751 are agriculturists, and 278,889 non-agriculturists. There are no manufactures of any note in the district, but each large village has its little colony of weavers, and fireworks are made in Bharáich and Nánpárá. Revenue in 1871, £130,000; of which £116,000, or 89 per cent., was derived from the land. District civil expenditure, £10,147. The last land revenue settlement was completed in 1871, and expires at different periods between 1897 and 1901. The regular police number, besides the village watch, 465 men, maintained at a cost of £5850. Education is backward. The central school at Bharáich has 105 pupils; and 3 Anglo-vernacular, with 41 vernacular village schools throughout the district, have 1649 pupils. Principal towns:—(1.) Bharáich, built on the extreme edge of the plateau described above, where it sinks sharply down upon the plains of Oudh; height above sea-level, 420 feet; population, 18,889; municipal income in 1871, £2177, 14s.; rate of taxation, 2s. 3½d. per head; (2.) Nánpárá, population, 6858; municipal income in 1871, £337, 8s.; rate of taxation, 11⅝d. per head; (3.) Jainal, population, 4510.

BHARTPUR, or BHURTPORE, a native state of Rájputáná in Upper India, under the political superintendence of the British Government, lying between 26° 48′ and 27° 50′ N. lat., and 76° 54′ and 77° 49′ E. long. It is bounded on the N. by the British district of Gurgáon, on the N.E. by Mathurá, on the E. by Agra, on the S. and S.W. by the Rájput states of Karaulí and Jaipur, and on the W. by the state of Alwar. Length from north to south, about 77 miles; greatest breadth, 50 miles; area, 1974 square miles. The country is generally level, about 700 feet above the sea. Small detached hills, rising to 200 feet in height, occur, especially in the northern part. These hills contain good building stone for ornamental architecture, and in some of them iron ore is abundant. The Bangangá is the only river which flows through the state. It takes its rise at Manoharpur in the territory of Jaipur, and flowing eastward passes through the heart of the Bhartpur state, and joins the Jamná below Agra.

In 1871–72 the population of Bhartpur amounted to 743,710 souls, consisting chiefly of Játs professing Hinduism, to which tribe the Rájá or chief of the state belongs. The Játs are one of the ancient Indo-Germanic races of India; by religion, Musalmáns in the west of Hindustan, Hindus in the east, and Sikhs in the Panjáb. The Játs make excellent cultivators, hardworking, thrifty, and energetic in the arts of peace as in those of war. Principal crops:—wheat, Indian corn, cotton, pulses, and sugar. The want of water is much felt; but the soil, though in many places sandy, is rendered highly productive by well-irrigation. The saline tracts yield salt of an inferior quality. Chief routes:—Mathurá to Mhau (Mhow) *via* Bhartpur town; Mathurá to Nasírábád, through Bhartpur town; Mathurá to Alwar, through Díg town; Agra to Ferozpur, through the towns of Bhartpur, Díg, and Kumbher; Agra to Ajmír, by Wáer. Principal towns:—Bhartpur, Díg, Wáer, Kumbher, and Bianá.

Bhartpur rose into importance under Súraj Mall, who bore a conspicuous part in the destruction of the Dehli empire. Having built the forts of Díg and Kumbher in 1730, he received in 1756 the title of Rájá, and subsequently joined the great Marhattá army with 30,000 troops. But the misconduct of the Marhattá leader induced him to abandon the confederacy, just in time to escape the murderous defeat at Pániput. Súraj Mall raised the Ját power to its highest point; and Colonel Dow, in 1770, estimated the Rájá's revenue (perhaps extravagantly) at £2,000,000, and his military force at 60,000 or 70,000 men. In 1803 the East India Company concluded a treaty, offensive and defensive, with Bhartpur. In 1804, however, the Rájá assisted the Marhattás against the British. The English under Lord Lake captured the fort of Díg and besieged Bhartpur, but was compelled to raise the siege after four attempts at storming. A treaty, concluded on 17th April 1805, guaranteed the Rájá's territory; but he became bound to pay £200,000 as indemnity to the East India Company. A dispute as to the right of the succession again led to a war in 1825, and Lord Combermere captured Bhartpur with a besieging force of 20,000 men, after a desperate resistance, on the 18th January 1826. The fortifications were dismantled, the hostile chief being deported to Benares, and an infant son of the former Rájá installed under a treaty favourable to the Company. In 1853 the Bhartpur ruler died, leaving a minor heir. The state came under British management, and the administration has been improved, the revenue increased,

a system of irrigation developed, new tanks and wells constructed, and an excellent system of roads and public buildings organized. In 1871–72 the revenue of the Bhartpur state amounted to £261,957. For educational purposes one college and 147 schools, with 3908 students, are maintained at an annual expenditure of £1821. The military force of the state consists of 1500 cavalry, 1500 infantry, and 200 artillery. The police force numbers 2200 men. Owing to the hot winds blowing from Rájputáná, the climate of Bhartpur is extremely sultry till the setting in of the periodical rains. Bhartpur city, the capital, lies in 27° 12′ N. lat. and 85° 49′ E. long.

BHATGÁON, a town of Northern India, in the Nepál valley, situated in 27° 37′ N. lat. and 85° 22′ E. long. It is a celebrated place of Hindu superstition, the favourite residence of the Bráhmans of Nepál, and contains more families of that order than either Kátmandu or Patu. It contains 12,000 houses, and its palace and buildings generally are of a more striking appearance than in other Nepálese towns. The town is said to possess many Sanskrit libraries.

BHATNIÁR, or BHATTIS, a people of the northern part of Hindustán, inhabiting the tract of country now included within the British district of Hissar, formerly called Bhatiáná, the eastern frontier of which is situated 125 miles north-west of Dehli. The Bhattis present many peculiarities in manners and customs, distinguishing them from the other people of Hindustán. They consist of two distinct races—the one being composed of Mahometans of Rájput descent, who constitute the influential class, and who report among themselves that their ancestors emigrated some centuries ago from the district of Jasalmír, and after various vicissitudes settled in the Bhatniár country; the other comprising the common people, known as Játs, who have adopted the religion of their superiors, and are consequently treated with great moderation. Most of these people are descended from dwellers on the western bank of the Satlej, who were invited by a Rájá of the Bhattis to cross the river and settle in his country. Though tillers of the soil, the Bhattis are more generally characterized as shepherds; and though they are mostly restricted to the territory whence their name is derived, various tribes of them are to be found in the Panjáb, and they are also scattered over the high grounds to the east of the Indus.

Notwithstanding they are Mahometans, their customs are in some respects at variance with those observed by the majority of the followers of the prophet, particularly in the females appearing, without reserve, unveiled in public, and in their associating openly with the men. The wives of the Rájput chiefs form an exception.

The territory above described, anterior to British sway, was under the dominion of a prince or Rájá, whose authority was acknowledged by inferior chiefs. This potentate could bring 20,000 or 30,000 men into the field, but they were quite undisciplined, and despised the necessary principle of subordination. His revenue arose chiefly from the plunder his troops secured; for their wars were directed more to predatory purposes than to open contest, and the Rájá, instead of repressing the ravages of this immense banditti, willingly participated in the spoils.

While under the influence of native rule the Bhattis appear to have formed a collection of hordes of freebooters. They have been described as of a cruel, savage, and ferocious disposition, entertaining an abhorrence of the usages of civilized life—thieves from their earliest infancy, and during their predatory incursions into the neighbouring districts, not scrupling, though unresisted, to add murder to robbery.

Many of the Bhattis appear to be constantly changing their residence from place to place as subsistence fails. Their exports are horses, camels, bullocks, buffaloes, and ghí; occasionally they sell some surplus grain above what is necessary for their own consumption, but their traffic is very inconsiderable. A large portion of the country is unproductive, but along the banks of the River Ghágar, from Bhatniár to the town of Sírsá, and also in the vicinity of the Naiwál (Nalá, or watercourse), the soil is uncommonly rich, and well adapted for cultivation. The inundations of these rivers fertilize their banks, and the subsidence of the waters leaves a broad margin prepared for plentiful crops of wheat, rice, and barley, which amply reward the labours of the husbandman.

The former capital of the Bhattis was Bhatniár, which lies in a situation almost inaccessible to an enemy, for no water is to be procured within 12 miles but what supplies the inhabitants. It was taken, however, in 1398 by Timur, more recently by the military adventurer George Thomas, and finally in 1805 by the Rájá of Bikánir, who still retains authority over it. The principal town is Sírsá, between which and Bháwalpur a route for commercial purposes has been opened. Numbers of the Bhattis have emigrated from their native country to establish themselves in the western parts of the dominions of Oudh; and several families of them are to be met with in Rohilkhand. They are practised travellers, and well trained to emigration by the laborious journeys undertaken in crossing the great desert to the west of their territories. During the independence of their native rulers, expeditions were frequently made in large parties for the purpose of predatory incursions on peaceable countries more remote; and these banditti displayed both skill and determination in attaining their object. Camels previously laden with provisions were despatched to different stations in the desert, which is about 130 miles in breadth, and their loads deposited there. The most intelligent of the party about to follow were then selected as guides, and enforced the most implicit obedience on their companions during the journey, which closed at the frontier of the hostile country, or rather that against which their hostility was directed. The guides by long experience became expert without compass or landmark, and seldom failed to conduct the party to the appointed station where the provisions were deposited, and thence across the remainder of the desert in safety. If accidentally they missed the points of rendezvous, or those where alone their necessities could be relieved, they were exposed to inevitable destruction. The adventurers steered their course by the sun in the day-time, and by the polar star at night; and by similar aids they were enabled to retrace the way they had travelled.

The history of the Bhattis has attracted the notice of few European authors. They seem to have carried on frequent wars with neighbouring states, and were the most formidable enemies opposed to the Rájá of Bikánir. The latter, however, invaded their territories in the beginning of the present century, and obtained some temporary advantages. He erected a fortress in Batinda, now a possession of the Rájá of Patíálá, and this contributed to overawe them for a time, and repressed their incursions into his own dominions, as, independently of the garrison, he stationed a large body of cavalry in the fort, whose frequent sallies and captures of cattle annoyed the Bhattis so much that they contemplated a total emigration from their own country. But George Thomas, the military adventurer already noticed, an Irishman by birth, who, endowed with singular talents and intrepidity, had founded for himself an independent state in the north-west of India, was then at war with the province of Bikánir. Having reached its frontiers, the Bhattis solicited his alliance, and, to induce him to espouse their cause the more readily, offered him 40,000 rupees if he would reduce the obnoxious

fort. In the prosecution of the war several actions ensued, and various fortresses were taken; but it would appear that one of the Bhatti chiefs at variance with General Thomas commenced hostilities against him about the period now alluded to; and in this new warfare with his late allies his forces were so much reduced by repeated encounters, that, being scarcely able to stand an engagement, he fortified his camps. The Bhattis, after frequent attacks, withdrew their troops by night; whereupon General Thomas took and burned Fathiábád and other places, and might have occupied the whole country, had not a neighbouring chief concluded an alliance with the Bhattis, and sent 1000 cavalry to their aid. General Thomas retreated to Jaijar, a town within his own territory, leaving the Bhattis in possession of their capital.

The triumphs of the British arms proved fatal to the European adventurers who at that period had established themselves in Northern India, and the arrangements made with Sindia brought the British into contact with the country of the Bhattis, against whom they were compelled in 1810 to march a force, which expelled the chief, and transferred the greater part of the territory to his son, who had voluntarily proceeded to the British camp.

BHÁWALPUR, a feudatory state in North-Western India, under the political jurisdiction of the Lieutenant-Governor of the Panjáb, lying between 27° 41′ and 30° 25′ N. lat., and 69° 30′ and 73° 58′ E. long. It is bounded on the N. by Sind and Panjáb, on the E. and S.E. by the British district of Hissar and the Rájput states of Bikánir and Jasalmír, and on the S.W. by Sind. The state contains an estimated area of about 22,000 square miles; greatest length from N.E. to S.W., 310 miles; greatest breadth, 110 miles. Only a sixth part of the total area is capable of cultivation.

Thornton thus describes the general aspect of the state:—"Bháwalpur is a remarkably level country, there being no considerable eminence within its limits, as the occasional sand-hills, seldom exceeding 50 or 60 feet in height, cannot be considered exceptions. The cultivable part extends along the river line for a distance of about 10 miles in breadth from the left or eastern bank. In the sandy part of the desert beyond this strip of fertility both men and beasts, leaving the beaten path, sink as if in loose snow. Here, too, the sand is raised into ever-changing hills by the force of the wind sweeping over it. In those parts of the desert which have a hard level soil of clay, a few stunted mimosas, acacias, and other shrubs are produced, together with rue, various bitter and aromatic plants, and occasionally tufts of grass. Much of the soil of the desert appears to be alluvial; there are numerous traces of streams having formerly passed over it, and still, where irrigation is at all practicable, fertility in the clayey tract follows; but the rains are scanty, the wells few and generally 100 feet deep or more."

The Ghará, a great stream formed by the united waters of the Biás and Satlej, the Indus, and the Panjnad, are the principal rivers of the state, affording a continuous river-line of 300 or 350 miles in length. In 1872 the population was estimated at 472,791, the majority of whom are Mahometans, consisting of Jats of Hindu descent, Beluchís, and Afghans. The principal products are woollen and cotton cloths, silk goods, indigo, cereals, alum, saltpetre, &c. These form the principal exports; the imports are inconsiderable. Value of external trade in 1872, £358,000; internal trade, £444,700. Principal trade routes:—(1), From Bikánir to Central Asia *via* Bhawalpur; (2), from Jasálmír to Afghánistán; (3), from Bháwalpur to Sind. In 1872 the gross revenue of the state was returned as £197,344; estimated military force, 2679. Principal towns—Bhawalpur, the capital, situated on a branch of the River Ghara; Ahmadpur, Uch, Khánpur, and Michinábád.

The state was a dependency of the Durání kingdom till its dismemberment, when Bháwalpur became independent. On the rise of Ranjit Singh, the khán of Bháwalpur tendered his allegiance to the British Government, and received a life-pension of £10,000 per annum for his services in the Sikh war. The present ruler is a minor (1875), and the state is now under British management, under which it has greatly prospered. The Panjáb Administration Report for 1871–72 states that on the death of the late chief, when Bháwalpur came under British management, "the treasury was empty, the Government in debt, the army disorganized, the canals, on which cultivation mainly depends, neglected, while a general sense of insecurity prevailed; but now (1871–72) there is a cash balance of £80,000 in hand, the state debts have been paid off, the revenue has reached £200,000 a year (or double what it was three years ago), while the ordinary expenditure is about £160,000, the canals have been greatly increased in number and efficiency, waste lands have been brought under cultivation, population has increased, and the army has been reorganized."

BHIL, a tribe and a British political agency in Central India. The political agency comprises the following native states:—(1.) Dhár, revenue in 1871–72, £60,000, expenditure £55,000; (2.) Bakhtnagar, revenue £5933, expenditure £4495; (3.) Jabuá, revenue £11,000, expenditure the same; (4.) Alírájpur, revenue £12,095, expenditure £10,783; (5.) Matwash, revenue, £620, expenditure £334; (6.) Jobat, revenue £1500, expenditure £1200; (7.) Katiwárá; (8.) Ratanmall; (9.) Amjherá, Dektán, Ságar, Báng, Bankánir, and Manáwan, belonging to Sindhiá; and (10.) Pitláwad and Chikáldá, belonging to Holkár. The Bhil agency comprises an area of 8160 square miles, with a population of 240,000 souls, and consists of—(1.) Mánpur Parganá (British); (2.) Barwání state (under British management in 1871–72); (3.) Jamniá, Rájgash, Garhi, and other Bhumiá chiefdoms; (4.) Holkár's districts south of the Vindhyan range; and (5.) Dewas or Bágod Parganá. The Bhil agency was formed in 1825, when the Bhil corps was organized, with a view to utilizing the warlike instincts of the Bhil tribes. This brave body of men have done good service, and gradually put down the predatory habits of their countrymen. The Bhil tribes chiefly inhabit the rocky ranges of the Vindhya and Sátpurá mountains, and the banks of the Narbadá and the Taptí. In common with other hill tribes, the Bhils are supposed to have been aborigines of India, and to have been driven to their present fastnesses at the time of the Hindu invasion. They are of dark complexion and diminutive stature, but active, and capable of enduring great fatigue. Various efforts have been made by the British Government to reclaim this people from their predatory habits, and in 1869–70 the official report stated that "the Bhils of Mánpur are becoming reconciled to the life of cultivators, though not yet willing to take out leases."

BHOPÁL, a British political agency in Central India, comprising 31 native administrations classified as follows:—First, Bhopál, a treaty state, its ruler having the power of life and death; second, Rájgarh and Narsinghgarh, the rulers of which receive salutes, and exercise independent civil and criminal jurisdiction, but submit proceedings in cases of heinous crime for the political agent's review; third, Kilchipur, Kurwál, and Maksúdnagar, the chiefs of which receive no salute, but possess independent authority, except in heinous offences; fourth, Pathárí, Basaudá, and Muhammadgarh, lesser chiefships, under the more direct supervision of the political agent; Laráwát, the chief of this is a *jágírdár* or holder of a grant of land under life tenure, and is subordinate to the political agent in all matters of administration; fifth, sixteen petty chiefs called *thákurs* and *jágírdárs*; sixth, four districts of other native states not within the jurisdiction of this agency. The Bhopál political agency is subordinate to the Central India agency.

BHOPÁL, a native state in Malwa in Central India, under the political superintendence of the British Government, lying between 22° 32′ and 23° 46′ N. lat., and 76° 25′ and 78° 50′ E. long. It is bounded on the N. by the state of Gwalior and the British district of Bairsiá, on the N.E. and S.E. by the Ságar and Ner-

badá territory, on the S.W. by the possessions of Holkár and Sindhiá, and on the N.W. by Sindhiá's districts and Omatwárá. Length of the state from E. to W., 157 miles; breadth from N. to S., 76 miles; estimated area, 6764 square miles. The surface of the country is uneven, being traversed by the Vindhya ranges, a peak of which near Raysen is upwards of 2500 feet above sea-level. The general inclination of the country is towards the north, in which direction most of the streams of the state flow, while others, passing through the Vindhyan ranges, flow to the Narbadá. The population of the state is estimated at 663,656, comprising Hindus, Mahometans, and the Gonds, an aboriginal tribe. Principal crops: wheat, Indian corn, oil-seeds, pulses, opium. Chief routes: (1), from Ságar through the town of Bhopál to the British cantonment of Mhow; (2), from Bhilsá to Hoshangábád and thence to Mhow; (3), from Hoshangábád to Nimach; (4), from Jabalpur through Hoshangábád to Mhow. Principal towns: Bhopál the capital, Islámnagar, Ashtá, Sihor, and Ráisen. In 1871–72 the annual income of the state was estimated at £240,000. Bhopál state was founded in 1723 by Dost Muhammad Khán, an Afghán adventurer. In 1818 a treaty of dependence was concluded between the chief and the British Government. Since then Bhopál has been steadily loyal to the British Government, and during the mutiny it rendered good services. The present ruler is a lady, and both she and her mother, who preceded her as head of the state, have displayed the highest capacity for administration. Both have been appointed Knights of the Star of India, and their territory is the best governed native state in India.

BHUTÁN, an independent kingdom in the Eastern Himálayas, between 26° and 28° N. lat., and 89° and 93° E. long. It is bounded on the N. by Thibet; on the E. by a tract inhabited by various uncivilized independent mountain tribes; on the S. by the British province of Assam, and the district of Jalpáigurí; and on the W. by the independent native state of Sikim. The whole of Bhután presents a succession of lofty and rugged mountains abounding in picturesque and sublime scenery. "The prospect," says Captain Turner, "between abrupt and lofty prominences is inconceivably grand; hills clothed to their very summits with trees, dark and deep glens, and the high tops of mountains lost in the clouds, constitute altogether a scene of extraordinary magnificence and sublimity." As might be expected from its physical structure, this alpine region sends out numerous rivers in a southerly direction, which, forcing their passage through narrow defiles, and precipitated in cataracts over the precipices, eventually pour themselves into the Brahmaputra. One torrent is mentioned by Turner as falling over so great a height that it is nearly dissipated in mid-air, and looks from below like a jet of steam from boiling water. Of the rivers traversing Bhután, the most considerable is the Manás, flowing in its progress to the Brahmaputra under the walls of Tásgáon, below which it is unfordable. At the foot of Tásgáon Hill it is crossed by a suspension bridge. The other principal rivers are the Máchu, Tchinchu, Torshá, Mánchi, and Dharlá.

Previous to the British annexation of the Dwárs from Bhután, the area of the kingdom was reckoned at 20,000 sq. miles. The population of the country now remaining to Bhután was estimated in 1864 at 20,000 souls. Later information, however, points to a larger figure. The people are industrious, and devote themselves to agriculture, but from the geological structure of the country, and from the insecurity of property, regular husbandry is limited to comparatively few spots. The people are oppressed and poor. "Nothing that a Bhutiá possesses is his own," wrote the British envoy in 1864; "he is at all times liable to lose it if it attracts the cupidity of any one more powerful than himself. The lower classes, whether villagers or public servants, are little better than the slaves of higher officials. In regard to them no rights of property are observed, and they have at once to surrender anything that is demanded of them. There never was, I fancy, a country in which the doctrine of 'might is right' formed more completely the whole and sole law and custom of the land than it does in Bhután. No official receives a salary; he has certain districts made over to him, and he may get what he can out of them; a certain portion of his gains he is compelled to send to the Darbár; and the more he extorts and the more he sends to his superior, the longer his tenure of office is likely to be." Captain Pemberton thus describes their moral condition—"I sometimes saw a few persons in whom the demoralizing influences of such a state of society had yet left a trace of the image in which they were originally created, and where the feelings of nature still exercised their accustomed influence, but the exceptions were rare, and although I have travelled and resided amongst various savage tribes on our frontiers, I have never yet known a people so wholly degraded as the Bhutiás." Physically the Bhutiás are a fine race, although dirty in their habits and persons. Their food consists of meat, chiefly pork, turnips, rice, barley-meal, and tea made from the brick-tea of China. Their favourite drink is *chong*, distilled from rice or barley and millet, and *Marwá*, beer made from fermented millet. A loose woollen coat reaching to the knees, and bound round the waist by a thick fold of cotton cloth, forms the dress of the men; the women's dress is a long cloak with loose sleeves. The houses of the Bhutiás are of three and four stories; all the floors are neatly boarded with deal; and on two sides of the house is a verandah ornamented with carved work generally painted. The Bhutiás are neat joiners, and their doors, windows, and panelling are perfect in their way. No iron-work is used; the doors open on ingenious wooden hinges. The appearance of the houses is precisely that of Swiss chalets, picturesque and comfortable—the only drawback being a want of chimneys, which the Bhutiás do not know how to construct. The people nominally profess the Buddhist religion, but in reality their religious exercises are confined to the propitiation of evil spirits, and the mechanical recital of a few sacred sentences. Around the cottages in the mountains the land is cleared for cultivation, and produces thriving crops of barley, wheat, buckwheat, millet, mustard, chillies, &c. Turnips of excellent quality are extensively grown; they are free from fibre and remarkably sweet. The wheat and barley have a full round grain, and the climate is well adapted to the production of both European and Asiatic vegetables. Potatoes have been introduced. The Bhutiás lay out their fields in a series of terraces cut out of the sides of the hills; each terrace is riveted and supported by stone embankments, sometimes twenty feet high. Every field is carefully fenced with pine branches, or protected by a stone wall. A complete system of irrigation permeates the whole cultivated part of a village, the water being often brought from a long distance by stone aqueducts. Bhutiás do not care to extend their cultivation, as an increased revenue is exacted in proportion to the land cultivated, but devote their whole energies to make the land yield twice what it is estimated to produce. The forests of Bhután abound in many varieties of stately trees. Among them are the beech, ash, birch, maple, cypress, and yew. Firs and pines cover the mountain heights; and below these, but still at an elevation of eight or nine thousand feet, is a zone of vegetation, consisting principally of oaks and rhododendrons. The cinnamon tree is also found. Some

of the roots and branches were examined by Turner during his journey to Thibet; but the plant being neither in blossom nor bearing fruit, it was impossible to decide whether it was the true cinnamon or an inferior kind of cassia. The leaf, however, corresponded with the description given of the true cinnamon by Linnæus. The lower ranges of the hills abound in animal life. Elephants are so numerous as to be dangerous to travellers; but tigers are not common, except near the River Tistá. Leopards abound in the Hah valley; deer everywhere, some of them of a very large species. The musk deer is found in the snows, and the barking deer on every hill side. Wild hogs are met with even at great elevations. Large squirrels are common. Bears and rhinoceros are also found. Pheasants, jungle fowls, pigeons, and other small game abound. The Bhutiás are no sportsmen. They have a superstitious objection to firing a gun, thinking that it offends the deities of the woods and valleys, and brings down rain. A species of horse, which seems indigenous to Bhután, and is used as a domestic animal, is called *tángan*, from Tángastán, the general appellation of that assemblage of mountains which constitutes the territory of Bhután. It is peculiar to this tract, not being found in any of the neighbouring countries of Assam, Nepál, Thibet, or Bengal, and unites in an eminent degree the two qualities of strength and beauty. The *tángan* horse usually stands about thirteen hands high, is short bodied, clean-limbed, deep in the chest, and extremely active, his colour usually inclining to piebald. In so barren and rude a country the manufacturing industry of its people is, as might be expected, in a low stage, the few articles produced being all destined for home consumption. These consist of coarse blankets and cotton cloths made by the villagers inhabiting the southern tract. Leather, from the hide of the buffalo, imperfectly tanned, furnishes the soles of snow boots. Circular bowls are neatly turned from various woods. A small quantity of paper is made from a plant described as the *Daphne papyrifera*. Swords, iron spears, and arrow-heads, and a few copper caldrons fabricated from the metal obtained in the country, complete the list of manufactures. The foreign trade of Bhután has greatly declined. In 1809 the trade between Assam and Bhután amounted to £20,000 per annum, the lac, madder, silk, *erendi* cloth, and dried fish of Assam, being exchanged for the woollens, gold-dust, salt, musk, horses, and silk of Bhután. At present very little trade is carried on by Bhután with the neighbouring countries. The military resources of the country are on an insignificant scale. Beyond the guards for the defence of the various castles, there is nothing like a standing army. The total military force was estimated by the British envoy in 1864 at 6000. The climate of Bhután varies according to the difference of elevation. At the time when the inhabitants of Punákhá (the winter residence of the Rájás) are afraid of exposing themselves to the blazing sun, those of Ghásá experience all the rigour of winter, and are chilled by perpetual snows. Yet these places are within sight of each other. The rains descend in floods upon the heights; but in the vicinity of Tásisudon, the capital, they are moderate; there are frequent showers, but nothing that can be compared to the tropical rains of Bengal. Owing to the great elevation and steepness of the mountains, dreadful storms arise among the hollows, often attended with fatal results.

History.—Bhután formerly belonged to a tribe called by the Bhutiás Tephu, generally believed to have been the people of Kuch Behar. About two hundred years ago some Thibetan soldiers subjugated the Tephus, took possession of the country, and settled down in it. At the head of the Bhután government there are nominally two supreme authorities, the Dharm Rájá, the spiritual head, and the Deb Rájá, the temporal ruler. To aid these Rájás in administering the country, there is a council of permanent ministers, called the Lenehen. Practically, however, there is no government all. Subordinate officers and rapacious governors of forts wield all the power of the state, and tyranny, oppression and anarchy reign over the whole country. The Dharm Rájá succeeds as an incarnation of the deity. On the death of a Dharm Rájá a year or two elapses, and the new incarnation then reappears in the shape of a child who generally happens to be born in the family of a principal officer. The child establishes his identity by recognizing the cooking utensils, &c., of the late Dharm Rájá; he is then trained in a monastery, and on attaining his majority is recognized as Rájá, though he exercises no more real authority in his majority than he did in his infancy. The Deb Rájá is in theory elected by the council. In practice he is merely the nominee of whichever of the two governors of East and West Bhután happens for the time to be the more powerful. The relations of the British with Bhután commenced in 1772, when the Bhutiás invaded the principality of Kuch Behar, a dependency of Bengal. The Kuch Behar Rájá applied for aid, and a force under Captain James was despatched to his assistance; the invaders were expelled and pursued into their own territories. Upon the intercession of Teshu Lama, then regent of Thibet, a treaty of peace was concluded in 1774 between the East India Company and the ruler of Bhután. In 1783 Captain Turner was deputed to Bhután, with a view of promoting commercial intercourse, but his mission proved unsuccessful. From this period little intercourse took place with Bhután, until the occupation of Assam by the British in 1826. It was then discovered that the Bhutiás had usurped several tracts of low land lying at the foot of the mountains, called the Dwárs or passes, and for these they agreed to pay a small tribute. They failed to do so, however, and availed themselves of the command of the passes to commit depredations within the British territory. Captain Pemberton was accordingly deputed to Bhután to adjust the points of difference. But his negotiations yielded no definite result; and every other means of obtaining redress and security proving unsuccessful, the Assam Dwárs were wrested from the Bhutiás, and the British Government consented to pay to Bhután a sum of £1000 per annum as compensation for the resumption of their tenure, during the good behaviour of the Bhutiás. Continued outrages and aggressions were, however, committed by the Bhutiás on British subjects in the Dwárs. Notwithstanding repeated remonstrances and threats, scarcely a year passed without the occurrence of several raids in British territory headed by Bhutiá officials, in which they plundered the inhabitants, massacred them, or carried them away as slaves. In 1863 Mr Ashley Eden was sent as an envoy to Bhután to demand reparation for these outrages. He did not succeed in his mission; he was subjected to the grossest insults; and under compulsion signed a treaty giving over the disputed territory to Bhután, and making other concessions which the Bhután Government demanded. On Mr Eden's return the viceroy at once disavowed his treaty, sternly stopped the former allowance for the Assam Dwárs, and demanded the immediate restoration of all British subjects kidnapped during the last five years. The Bhutiás not complying with this demand, the Governor-General issued a proclamation, dated the 12th November 1864, by which the eleven Western or Bengal Dwárs were forthwith incorporated with the Queen's Indian dominions. No resistance was at first offered to the annexation; but, suddenly, in January 1865, the Bhutiás surprised the English garrison at Diwángiri, and the post was abandoned with

the loss of two mountain train guns. This disaster was soon retrieved by General Tombs, and the Bhutiás were compelled to sue for peace, which was concluded on the 11th November 1865. The Bhután Government formally ceded all the eighteen Dwárs of Bengal and Assam, with the rest of the territory taken from them, and agreed to liberate all kidnapped British subjects. As the revenues of Bhután mainly depended on these Dwárs, the British Government, in return for these concessions, undertook to pay the Deb and Dhárm Rájás annually, subject to the condition of their continued good behaviour, an allowance beginning at £2500 and rising gradually to a maximum of twice that amount. Since that time nothing of importance has occurred, and the annexed territories have settled down into peaceful and prosperous British districts.

BIAFRA, a tract of country on the coast of Western Africa, on a bay or bight of the same name. Lander, in descending the Niger, arrived in the Bight of Biafra, and thus left no doubt that the system of inter-ramified river-channels, extending from Benin to Biafra, constitutes the delta of that river. The Bight of Biafra, or Mafra, is the most eastern part of the Gulf of Guinea, between Capes Formosa and Lopez; it contains the islands of Fernando Po, Prince's, and St Thomas's.

BIANCHINI, Francis, a learned Italian astronomer and antiquary, was born at Verona in 1662, of a noble and ancient family. He was educated at Padua, and devoted himself especially to mathematics and classics. In 1684 he went to Rome, and was made librarian to Cardinal Ottoboni, afterwards Pope Alexander VIII. He was made canon of Sta Maria de la Rotonda, and afterwards of St Lorenzo in Damaso. His first work seems to have been a treatise directed against the Copernican system; it was published about 1680. In 1697 appeared the first and only volume of his *Universal History*, coming down to the close of the Assyrian empire. His later works, with the exception of the *Hesperi et Phosphori nova Phænomena*, a series of observations on Venus, were chiefly upon the ruins excavated on the Via Appia and Mount Palatine. He died in 1729.

BIARRITZ, a watering-place in the south of France, in the department of Basses-Pyrénées, on the sea-coast about five miles south-west of Bayonne. From a mere fishing village, with a few hundred inhabitants, in the beginning of the century, it rose rapidly into a place of importance under the patronage of the late emperor Napoleon III. and the empress, with whom it was a favourite resort. Excellent bathing-ground is afforded by the Vieux Port and the various sheltered bays into which the cliffs of this part of the coast are carved by the swell of the Atlantic; and the irregular eminences and promontories supply attractive sites for the erection of villas. The climate is delightful and bracing; and the bareness of the neighbourhood has been considerably relieved by fir plantations. Except the ruins of the castle of Atalaye, the lighthouse of Port Hart, the Villa Eugénie, erected for the empress in 1855–1856, the new French church, the English Protestant church, and the casino, there is no building with special claim to notice; the bathing establishments, cafés, and hotels are matters of course, but these are at least not unworthy the fame of the town. Since 1863, when it was decided that the construction of a new port was a matter of public utility, large sums of money have been expended in the attempt to form a satisfactory breakwater, but the severity of the winter storms has frequently interrupted the work. The permanent population of Biarritz, according to the census of 1871, was 3164; and the autumn visitors are estimated at from 12,000 to 15,000.

See Russell, *Biarritz and the Basque Countries*, 1873.

BIAS, a native of Priene, one of the seven sages of Greece, was the son of Teutamus, and flourished about the middle of the 6th century B.C. He was one of the most eloquent speakers of his time, and is celebrated as having never used his talents for purposes of mere gain, but as having devoted them to the service of the injured and oppressed. Many stories are told illustrative of the nobility of his character in this and other respects. According to one of these, when his native town was taken by an enemy, and the inhabitants were carrying off whatever seemed to each most valuable, one of them, observing Bias without any burden, advised him to follow his example. "I am doing so," said he, "for I carry all my valuables with me." His fellow-citizens honoured him with a splendid funeral, and dedicated to him a sanctuary which they called Teutamium. He is said to have written an heroic poem on the affairs of the Ionians, in order to show them how they might be most prosperous. A great number of the short, pithy, ethical sayings or apophthegms characteristic of the Greek sages are ascribed to Bias. Of these a few specimens may be given—"Be slow to enter on an undertaking, but when you have begun, persevere to the end;" "Know, and then act;" "Hear much, speak little;" "Do not praise an unworthy man on account of his wealth;" "Take (*i.e.*, gain your end) by persuasion, not by force;" "He is unfortunate who cannot bear misfortune;" "So order your affairs as if your life were to be both long and short." Bias is the author of the famous and often imitated reproof to the impious sailors, who in the midst of a tempest were calling on the gods—"Be quiet," said he, "lest the gods discover that you are here." (Diog. Laert., i. 82–88; Stobæus, *Floril.;* Mullach, *Frag. Ph. Græc.*, i. 203, *sqq.*)

BIBERACH, a town of Würtemberg, in the circle of the Danube, a capital of a bailiwick 23 miles S.S.W. of Ulm. It is situated on the River Riss, a small tributary of the Danube, partly on level ground and partly on hills, and still has a somewhat mediæval appearance from the remains of its ancient walls and towers. Its principal church dates from the 12th century, and it possesses a hospital with very extensive endowments. The main objects of its varied industry are toys, cloth goods of different kinds, lace, paper, and leather; and there are also bell-foundries and breweries. In the neighbourhood is the watering-place called Jordansbad. Biberach appears as a village in the 8th century, and in the 15th it became a free imperial city. During the Thirty Years' War it underwent various vicissitudes, and was for a good while held by the Swedes. In 1707 it was captured and put to ransom by the French, who afterwards, in 1796 and 1800, defeated the Austrians in the neighbourhood. In 1803 the city was deprived of its imperial freedom and assigned to Baden; and in 1806 it was transferred to Würtemberg. Biberach is the birthplace of the sculptor Natter and the painter Neher; and Wieland, who was born at the neighbouring village of Oberholzheim, spent a series of years in the town.

BIBIRINE, or Bebeerine, an alkaloid obtained from the bark and fruit of the greenheart tree, *Nectandra Rodiœi*, called bibiru or sipiri in Guiana, where the tree grows. The alkaloid was discovered about the year 1835 by Hugh Rodie, a surgeon resident in Demerara, who found it possessed great efficacy as a febrifuge, and it was recommended by him as a substitute for quinine. The sulphate of bibirine has a place in the British pharmacopœia, and is in considerable use in medicine as a bitter tonic and febrifuge. Bibirine has been shown by Walz to be apparently identical with an alkaloid obtained from the common box, *Buxus sempervirens*, called buxine, and this opinion is to some extent confirmed by Dr Flückiger. The sulphate of bibirine found in commerce is a dark brown substance in thin translucent scales.

BIBLE

Bible.

THE word BIBLE, which in English, as in Mediæval Latin, is treated as a singular noun, is in its original Greek form a plural,—τὰ βιβλία, *the* (*sacred*) *books*,—correctly expressing the fact that the sacred writings of Christendom are made up of a number of independent records, which set before us the gradual development of the religion of revelation. The origin of each of these records forms a distinct critical problem; and for the discussion of these questions of detail the reader is referred to the articles on separate Biblical books. The present article seeks to give a general account of the historical and literary conditions under which the unique literature of the Old and New Testaments sprang up, and of the way in which the Biblical books were brought together in a canonical collection and handed down from age to age. The Biblical development is divided into two great periods by the manifestation and historical work of Christ. In its pre-Christian stage the religion of revelation is represented as a *covenant* between the spiritual God and His chosen people the Hebrews. In accordance with this and in allusion to Jer. xxxi. 31, Jesus speaks of the new dispensation founded in His death as a new *covenant* (1 Cor. xi. 25). Hence, as early as the 2d century of our era the two great divisions of the Bible were known as the books of the Old and of the New Covenant respectively. Among Latin-speaking Christians the Greek word for covenant was often incorrectly rendered *testament*, and thus Western Christendom still uses the names of the Old and New Testaments.

Testament.

Religion of Israel.

OLD TESTAMENT.—*Struggle and Progress of Spiritual Religion. Priests, Prophets, &c.*—The pre-Christian age of the Biblical religion falls into a period of religious productivity and a subsequent period of stagnation and mainly conservative traditions. The period of productivity is also a period of contest, during which the spiritual principles of the religion of revelation were involved in continual struggle with polytheistic nature-worship on the one hand, and, on the other hand, with an unspiritual conception of Jehovah as a God whose interest in Israel and care for His sanctuary were independent of moral conditions. In this long struggle, which began with the foundation of the theocracy in the work of Moses, and did not issue in conclusive victory until the time of Ezra, the spiritual faith was compelled to show constant powers of new development,—working out into ever clearer form the latent contrasts between true and false religion, proving itself fitter than any other belief to supply all the religious needs of the people, and, above all, finding its evidence in the long providential history in which, from the great deliverance of the Exodus down to the Captivity and the Restoration, the reality of Jehovah's kingship over Israel, of His redeeming love, and of His moral government, were vindicated by the most indisputable proofs. As it was only the deliverance from Egypt and the theocratic covenant of Sinai that bound the Hebrew tribes into national unity, the worship of Jehovah was always acknowledged as the national religion of Israel. But from Joshua to Samuel national feeling was far weaker than tribal jealousy; and in the political disintegration of the people the religion of Jehovah seemed ready to be lost in local superstitions. During this period the chief centre of monotheism was the sanctuary and priesthood of the ark; and it was from the priestly circle that Samuel arose to reunite the nation by recalling it to the religion of Jehovah, and thus to prepare the way for the splendid age of David and Solomon. But though Samuel was by education a priest, it was not as a priest, but as a prophet that he accomplished this work.

Priests and prophets.

In all ages a priesthood is conservative, not creative; and it was only as a growing and creative power that the still undeveloped spiritual religion could live. While it was the business of the priest faithfully to preserve religious traditions already acknowledged as true and venerable, the characteristic of the prophet is a faculty of spiritual intuition, not gained by human reason, but coming to him as a word from God himself, wherein he apprehends religious truth in a new light, as bearing in a way not manifest to other men on the practical necessities, the burning questions of the present. Unlike the priesthood, the prophets never formed a regular guild. It was an axiom that the gift of prophecy was bestowed by the inward and immediate call of Jehovah. But from the time of Samuel we find a regular succession of prophets working out the spiritual problems of the national faith with ever increasing clearness, and gathering round them, sometimes in regularly formed communities, a circle of disciples and sympathizers which, though never, perhaps, numerically considerable, embraced the names of David and other leaders of Hebrew history, and impressed the stamp of prophetic influence on every part of the national life. From this time the priests hold only the second place in the history of the Old Testament religion; sometimes they even appear as the opponents of the prophetic party, whose progressive ideas are distasteful to their natural conservatism and aristocratic instincts. But on the whole, the more enlightened ministers of the central sanctuary continued to share with the prophets the task of upholding a lofty religious tradition, and not unfrequently both characters were united in one person. It was, in fact, only through the priests that the ideas of the prophets could receive public sanction in the ordinances of religion, as it was only through rulers like David, or Hezekiah, or Jehu, that they could influence the political conduct of affairs.

False views of prophecy.

A just insight into the work of the prophetic party in Israel was long rendered difficult by traditional prejudices. On the one hand the predictive element in prophecy received undue prominence, and withdrew attention from the influence of the prophets on the religious life of their own time; while, on the other hand, it was assumed, in accordance with Jewish notions, that all the ordinances, and almost, if not quite, all the doctrines of the Jewish church in the post-canonical period, existed from the earliest days of the theocracy. The prophets, therefore, were conceived partly as inspired preachers of old truths, partly as predicting future events, but not as leaders of a great development, in which the religious ordinances as well as the religious beliefs of the Old Covenant advanced from a relatively crude and imperfect to a relatively mature and adequate form.

The prophets and the law.

The proof that this latter view, and not the traditional conception, is alone true to history depends on a variety of arguments which cannot here be reproduced. That the religious ideas of the Old Testament were in a state of growth during the whole prophetic period became manifest as soon as the laws of grammatico-historical exegesis were fairly applied to the Hebrew Scriptures. That the sacred ordinances were subject to variation was less readily admitted, because the admission involved a change of view as to the authorship of the Pentateuch; but here also the facts are decisive. For example, the law in Exod. xx. 24, *ff.*, contemplates the worship of Jehovah on other altars than that of the central sanctuary (*cf.* Deut. xxxiii. 19). This practice, accordingly, was followed by Samuel, and was fully approved by Elijah (1 Kings xix. 14). But the worship

of Jehovah on the high places or local sanctuaries was constantly exposed to superstitious corruption and heathen admixture, and so is frequently attacked by the prophets of the 8th century. It was undoubtedly under their influence that Hezekiah abolished the high places. The abolition was not permanent; but in the reign of Josiah, the next reforming king, we find that the principle of a single sanctuary can claim the support not only of prophetic teaching, but of a written law-book found in the temple, and acknowledged by the high priest (2 Kings xxii., xxiii.) The legislation of this book corresponds not with the old law in Exodus, but with the book of Deuteronomy. But perhaps the clearest proof that, during the period of prophetic inspiration, there was no doctrine of finality with regard to the ritual law any more than with regard to religious ideas and doctrines, lies in the last chapters of Ezekiel, which sketch at the very era of the Captivity an outline of sacred ordinances for the future restoration. From these and similar facts it follows indisputably, that the true and spiritual religion which the prophets and like-minded priests maintained at once against heathenism and against unspiritual worship of Jehovah as a mere national deity without moral attributes, was not a finished but a growing system, not finally embodied in authoritative documents, but propagated mainly by direct personal efforts. At the same time these personal efforts were accompanied and supported by the gradual rise of a sacred literature.

Rise of a Sacred Literature.

Though the priestly ordinances were mainly published by oral decisions of the priests, which are, in fact, what is usually meant by the word *law* (Torah) in writings earlier than the Captivity, there can be no reasonable doubt that the priests possessed written legal collections of greater or less extent from the time of Moses downwards. Again, the example of Ezekiel, and the obvious fact that the law-book found at the time of Josiah contained provisions which were not up to that time an acknowledged part of the law of the land, makes it probable that legal provisions, which the prophets and their priestly allies felt to be necessary for the maintenance of the truth, were often embodied in legislative programmes, by which previous legal tradition was gradually modified. Then the prophets, especially when they failed to produce immediate reformation, began from the 8th century, if not still earlier, to commit their oracles to writing; and these written prophecies—circulating widely in a nation which had attained a high degree of literary culture, and frequently cited by later seers—disseminated prophetic teaching in a permanent form. Long before this time music and song had been practised in the prophetic circle of Samuel, and were introduced under David into the service of the sanctuary. Another important vehicle of religious instruction was the written history of the nation, which could not fail to be generally set forth in the theocratic spirit in which all loftier Hebrew patriotism had its root. And, indeed, the literary diffusion of spiritual ideas was not confined to the direct efforts of priest and prophets.

Popular religion.

In spite of the crass and unspiritual character of the mass of the people, the noblest traditions of national life were entwined with religious convictions, and the way in which a prophet, like Amos, could arise untrained from among the herdsmen of the wilderness of Judah, shows how deep and pure a current of spiritual faith flowed among the more thoughtful of the laity. Prophecy itself may from one point of view be regarded simply as the brightest efflorescence of the lay element in the religion of Israel, the same element which in subjective form underlies many of the Psalms, and in a shape less highly developed tinged the whole proverbial and popular literature of the nation; for in the Hebrew commonwealth popular literature had not yet sunk to represent the lowest impulses of national life.

Close of the Old Testament Development. Formation of the Canon.—

The Exile and Restoration.

The struggle between spiritual and unspiritual religion was brought to a crisis when the prophetic predictions of judgment on national sin were fulfilled in the fall of the kingdom of Judah. The merely political worship of Jehovah as the tutelary god of the state was now reduced to absurdity. Faith in the covenant God was impossible except on the principles of spiritual belief. Nor did the restoration by Cyrus affect this result. No political future lay before the returning exiles, and continued confidence in the destiny of the race was not separable from the religious ideas and Messianic hopes of the prophets. To obey the law of Jehovah and patiently to await the coming Deliverer was the only distinctive vocation of the community that gathered in the new Jerusalem; and after a period of misfortune and failure, in which the whole nation seemed ready to collapse in despair, this vocation was clearly recognized and embodied in permanent institutions in the reformation of Ezra and Nehemiah (445 B.C.)

Reformation and law-book of Ezra.

But with this victory the spiritual religion passed into a stationary state. The spirit of prophecy, long decadent, expired with Malachi, the younger contemporary of Nehemiah; and the whole concern of the nation from this time downwards was simply to preserve the sacred inheritance of the past. The Exile had so utterly broken all continuity of national life, that that inheritance could only be sought in the surviving monuments of sacred literature. To these, more than to the expiring voice of prophecy in their midst, the founders of the new theocracy turned for guidance. The books that had upheld the exiles' faith, when all outward ordinances of religion were lacking, were also the fittest teachers of the restored community. Previous reformers had been statesmen or prophets. Ezra is a scribe who comes to Jerusalem armed, not with a fresh message from the Lord, but with "the book of the law of Moses." This law-book was the Pentateuch, and the public recognition of it as the rule of the theocracy was the declaration that the religious ordinances of Israel had ceased to admit of development, and the first step towards the substitution of a *canon* or authoritative collection of Scriptures for the living guidance of the prophetic voice. A second step in the same direction is ascribed to Nehemiah by a tradition intrinsically probable, though of no great external authority. He, it is said, collected a library which, besides documents of temporary importance, embraced "the books about the kings and prophets, and the writings of David" (2 Mac. ii. 13.) Certainly a complete body of the remains of the prophets, with an authentic account of the history of the period of their activity, must soon have been felt to be scarcely second in importance to the law; and so Nehemiah may very well be supposed to have begun the collection which now forms the second part of the Hebrew Bible, embracing, under the general title of *The Prophets*, the historical books of Joshua, Judges, Samuel, Kings (*Earlier Prophets*), and the four prophetic books of Isaiah, Jeremiah, Ezekiel, and the twelve minor prophets (*Latter Prophets*).

Second canon.

The mention of the writings of David implies that Nehemiah also began the formation of the third and last part of the Hebrew canon, which comprises, under the title of *Ketubim* (Scriptures, Hagiographa), the Psalms, Proverbs, Job, the five Megillot or *rolls* (Canticles, Ruth, Lamentations, Ecclesiastes, Esther), and, finally, Daniel, Ezra, Nehemiah, and Chronicles.

Third canon.

It is certain, however, that this part of the collection was not completed till long after Nehemiah's time; for to say nothing of the disputed dates of Ecclesiastes and Daniel, the book of Chronicles contains genealogies which go down at least to the close of the Persian period. The miscellaneous character of the Ketubim seems, in fact, to show that after the Law and the Prophets were

closed, the third part of the canon was open to receive additions, recommended either by their religious and historical value, or by bearing an ancient and venerable name. And this was the more natural because the Hagiographa had not the same place in the synagogue service as was accorded to the Law and the Prophets.

Close of canon.

The time and manner in which the collection was absolutely closed is obscure. The threefold division of the sacred writings is referred to in the prologue to the Wisdom of Sirach (Ecclesiasticus) about 130 B.C., but Jewish tradition indicates that the full canonicity of several books, especially of Ecclesiastes, was not free from doubt till the time of the famous R. Akiba, who perished in the great national struggle of the Jews with the Emperor Hadrian (Mishna, *Jadaim*, 3; *Edaiot*, 5). The oldest list of canonical books, given by Josephus (*c. Apion.*, i. 8), is of somewhat earlier date. Josephus seems to have had quite our present canon; but he took Ruth along with Judges, and viewed Lamentations as part of the book of Jeremiah, thus counting twenty-two books instead of the twenty-four of the Talmudic enumeration and of the present Hebrew Bible. There is other evidence that only twenty-two books were reckoned by the Jews of the first Christian century; and it appears that this number was accommodated to that of the letters of the Hebrew alphabet. Even in the time of Jerome, Ruth and Lamentations were not uniformly reckoned apart. The expansion of the Talmudic twenty-four to the thirty-nine Old Testament books of the English version is effected by reckoning the minor prophets one by one, by separating Ezra from Nehemiah, and by subdividing the long books of Samuel, Kings, and Chronicles. In this reckoning, and in the very different order of the books, we follow in the main the Alexandrian Greek and Vulgate Latin versions. But the Alexandrian differed from the Hebrew canon in more important points. The line of distinction between inspired and human writings was not so sharply drawn; and the Greek Bible not only admitted additions to several of the Hagiographa, but contained other apocryphal books, of some of which Greek was the original tongue, while others were translations of Hebrew or Aramaic writings. See APOCRYPHA.

Number of canonical books.

Alexandrian canon.

In turning now to a literary and critical survey of the Old Testament books, we shall find it convenient to depart from the division of the Hebrew canon, in favour of a classification suggested by the order of the books followed in the English version and in most other translations. The Old Testament literature is made up of historical, poetico-didactic, and prophetic writings, and under these three heads we will arrange what remains to be said on the subject.

Historical Books.—These form two parallel series of sacred history. The books from Genesis to Kings give a continuous story (with some episodical additions) from the creation to the fall of the kingdom of Judah. The book of Chronicles covers the same ground on a narrower plan, contracting the early history into genealogical lists, and occupying itself almost entirely with the kingdom of Judah, and especially with matters connected with the temple and its worship. The narrative of the chronicler is continued in the books or rather book of Ezra and Nehemiah, which incorporates original memoirs of these two reformers, but otherwise is so exactly in the style of the Chronicles that critics are practically agreed in ascribing the whole to a single author, probably a Levite, who, as we have already seen, cannot have written before the close of the Persian empire. The questions that are raised as to the work of the chronicler belong less to the general history of Biblical literature than to special introduction. We pass on, therefore, to the larger and more important series. The Pentateuch and the so-called earlier prophets form together a single continuous narrative. It is plain, however, that the whole work is not the uniform production of one pen, but that in some way a variety of records of different ages and styles have been combined to form a single narrative. Accordingly, Jewish tradition bears that Moses wrote the Pentateuch, Joshua the book named after him, Samuel the book of Judges, and so forth. As all Hebrew history is anonymous,—a sure proof that people had not yet learned to lay weight on questions of authorship,—it is not probable that this tradition rests on any surer ground than conjecture; and, of course, a scribe who saw in the sacred books the whole outcome of Israel's history would naturally leap to the conclusion that the father of the Law was the author of the Pentateuch, and that the other leaders of Israel's history could not but be the writers of a great part of the Scriptures. A more careful view of the books themselves shows that the actual state of the case is not so simple. In the first place, the limits of the individual books are certainly not the limits of authorship. The Pentateuch as a law-book is complete without Joshua, but as a history it is so planned that the latter book is its necessary complement. (*Cf.*, for example, Exod. xvi. 35, Josh. v. 12; Gen. l. 24, 25; Exod. xiii. 19; Josh. xxiv. 32.) In truth, an author who wrote after the occupation of Canaan could never have designed a history which should relate all God's promises to Israel and say nothing of their fulfilment. But in its present shape the Pentateuch is certainly subsequent to the occupation, for it uses geographical names which arose after that time (Hebron, Dan), refers to the conquest as already accomplished (Deut. ii. 12, *cf.* Num. xv. 32; Gen. xii. 6), and even presupposes the existence of a kingship in Israel (Gen. xxxvi. 31). And with this it agrees, that though there are marked differences of style and language within the book of Joshua, each style finds its counterpart in some section of the Pentateuch. In the subsequent books we find quite similar phenomena. The last chapters of Judges cannot be separated from the book of Samuel, and the earlier chapters of Kings are obviously one with the foregoing narrative; while all three books contain passages strikingly akin to parts of the Pentateuch and Joshua (*cf.*, for example, the book of Deuteronomy with Josh. xxiii., 1 Sam. xii., 1 Kings viii.) Such phenomena not only prove the futility of any attempt to base a theory of authorship on the present division into books, but suggest that the history as we have it is not one narrative carried on from age to age by successive additions, but a fusion of several narratives which partly covered the same ground and were combined into unity by an editor. This view is supported by the fact, that even as it now stands the history sometimes gives more than one account of the same event, and that the Pentateuch often gives several laws on the same subject. Of the latter we have already had one example, but for our present argument the main point is not diversity of enactment, which may often be only apparent, but the existence within the Pentateuch of distinct groups of laws partly taking up the same topics. Thus the legislation of Exod. xx.-xxiii. is partly repeated in ch. xxxiv., and on the passover and feast of unleavened bread we have at least six laws, which if not really discordant, are at least so divergent in form and conception that they cannot be all from the same pen. (Exod. xii. 1-28, xiii. 3-10, xxiii. 15, xxxiv. 18; Lev. xxiii. 5-14, Deut. xvi.) Of historical duplicates the most celebrated are the twofold history of the creation and the flood, to which we must recur presently. The same kind of thing is found in the later books; for example, in the account of the way in which Saul became king, where it is scarcely possible to avoid the conclusion that 1 Sam. xi. 1-11 should attach directly to ch. x. 16 (*cf.* x. 7). But the extent to which the historical books are

The Chronicles.

Genesis to Kings—a single history.

Duplicate histories.

made up of parallel narratives which, though they cover the same period, do not necessarily record the same events, was first clearly seen after Astruc (1753 A.D.) observed that the respective uses of Jehovah (LORD) and Elohim (God) as the name of the Deity afford a criterion by which two documents can be dissected out of the book of Genesis. That the way in which the two names are used can only be due to difference of authorship is now generally admitted, for the alternation corresponds with such important duplicates as the two accounts of creation, and is regularly accompanied through a great part of the book by unmistakable peculiarities of language and thought, so that it is still possible to reconstruct at least the Elohim document with a completeness which makes its original independence and homogeneity matter of direct observation. The character of this narrative is annalistic, and where other material fails blanks are supplied by genealogical lists. Great weight is laid on orderly development, and the name Jehovah is avoided in the history of the patriarchs in order to give proper contrast to the Mosaic period (*cf.* Gen. xvii. 1; Exod. vi. 3); and, accordingly, we find that the unmistakable secondary marks of this author run through the whole Pentateuch and Joshua, though the exclusive use of Elohim ceases at Exod. vi. Of course the disappearance of this criterion makes it less easy to carry on an exact reconstruction of the later parts of the document; but on many points there can be no uncertainty, and it is clearly made out that the author has strong priestly tendencies, and devotes a very large proportion of his space to liturgical matters. The separation of this document may justly be called the point of departure of positive criticism of the sources of the Old Testament; and present controversy turns mainly on its relation to other parts of the Pentateuch. Of these the most important are—1. The Jehovistic narrative, which also begins with the creation, and treats the early history more in the spirit of prophetic theology and idealism, containing, for example, the narrative of the fall, and the parts of the history of Abraham which are most important for Old Testament theology. That this narrative is not a mere supplement to the other, but an independent whole, appears most plainly in the story of the flood, where two distinct accounts have certainly been interwoven by a third hand. 2. Many of the finest stories in Genesis, especially great part of the history of Joseph, agree with the Elohim-document in the name of God, but are widely divergent in other respects. Since the researches of Hupfeld, a third author, belonging to northern Israel, and specially interested in the ancestors of the northern tribes, is generally postulated for these sections. His literary individuality is in truth sharply marked, though the limits of his contributions to the Pentateuch are obscure.

Composition of the Pentateuch.

Priestly, prophetic, and popular narratives.

It will be remembered that we have already seen that three currents of influence run through the Old Testament development,—the traditional lore of the priests, the teaching of the prophets, and the religious life of the more enlightened of the people. Now, in the three main sections of the early history just enumerated we find the counterpart of each of these. The priestly narrative of the Elohist, the prophetic delineation of the Jehovist, the more picturesque and popular story of the third author, embody three tendencies, which are not merely personal but national, and which constantly reappear in other parts of Hebrew literature. Up to the book of Joshua all three run side by side But the priestly interest found little scope in the subsequent history; and from the time of the Judges we can generally distinguish only sections marked by prophetic pragmatism and others which, though distinctly religious and even theocratic, are, so to speak, written from a layman's stand-point. The latter comprise a large part of Judges, and by far the greatest part of Samuel, as well as the beginning of Kings. To the modern mind this part of the narrative, which is rich in colour and detail, is by far the most interesting, and it is with sincere regret that we pass at 1 Kings xi. to a division of the history for which the chief sources—cited as the Chronicles of the Kings of Israel and Judah respectively—treat almost exclusively of the outer political life of the nation. In striking contrast to the uniformity of this narrative are the interspersed histories of Elijah and other northern prophets. These histories are very remarkable in style and even in language; and, containing some of the noblest passages of the Old Testament, form one of many proofs of the unusual literary genius of the kingdom of Ephraim. But how are these various narratives related to each other? This question is not easy to answer. In general the third or lay element of the history seems to stand nearest to the events recorded, and even, perhaps, to form the direct basis of the prophetical matter; while, occasionally, old lists of names and places, poetico-historical pieces, and the like, form a still deeper stratum in the story. (Poetical pieces in the *Book of the Wars of Jehovah*, Num. xxi. 14; *Book of Jasher* [the upright], Josh. x. 13; 2 Sam. i. Lists like 2 Sam. xxiii.) Whether the same hands or only the same tendencies as appear in the non-Levitical parts of Genesis run on as far as the book of Kings, is a question which, though answered in the affirmative by Schrader and others, cannot be viewed as decided. Even the date of these elements of the Pentateuch is obscure; but in the 8th century Hosea refers quite clearly to passages of both. Thus far there is tolerable agreement among critics; but the Levitical or Elohistic history is the subject of violent controversy, which, however, turns mainly on the analysis of the legal parts of the Pentateuch. These contain other elements besides those already enumerated, of which we need only mention the brief code which follows the Decalogue in Exod. xx.–xxiii., and the great repetition of the law in a prophetic spirit which occupies the major part of Deuteronomy. Both these codes may be called popular in tone. They are precepts not for the priests, but for the whole people; and the former is the fundamental sketch of the whole theocratic constitution, which the latter develops and to some extent alters. Now the book of Deuteronomy presents a quite distinct type of style which, as has been already mentioned, recurs from time to time in passages of the later books, and that in such a connection as to suggest to many critics since Graf the idea, that the Deuteronomic hand is the hand of the last editor of the whole history from Genesis to Kings, or, at least, of the non-Levitical parts thereof. This conclusion is not stringent, for a good deal may be said in favour of the view that the Deuteronomic style, which is very capable of imitation, was adopted by writers of different periods. But even so it is difficult to suppose that the legislative part of Deuteronomy is as old as Moses. If the law of the kingdom in Deut. xvii. was known in the time of the Judges, it is impossible to comprehend Judg. viii. 23, and above all I Sam. viii. 7 That the law of high places given in this part of the Pentateuch was not acknowledged till the time of Josiah, and was not dreamed of by Samuel and Elijah, we have already seen. The Deuteronomic law is familiar to Jeremiah, the younger contemporary of Josiah, but is referred to by no prophet of earlier date. And the whole theological stand-point of the book agrees exactly with the period of prophetic literature, and gives the highest and most spiritual view of the law, to which our Lord himself directly attaches his teaching, and which cannot be placed at the beginning of the theocratic development without making the whole history unintelligible. Beyond doubt the book is, as already hinted, a prophetic legislative programme; and if the author put

The laws of the Pentateuch.

Deuteronomy

his work in the mouth of Moses instead of giving it, with Ezekiel, a directly prophetic form, he did so not in pious fraud, but simply because his object was not to give a new law, but to expound and develop Mosaic principles in relation to new needs. And as ancient writers are not accustomed to distinguish historical data from historical deductions, he naturally presents his views in dramatic form in the mouth of Moses. If then the Deuteronomic legislation is not earlier than the prophetic period of the 8th and 7th centuries, and, accordingly, is subsequent to the elements of the Pentateuchal history which we have seen to be known to Hosea, it is plain that the chronology of the composition of the Pentateuch may be said to centre in the question whether the Levitico-Elohistic document, which embraces most of the laws in Leviticus with large parts of Exodus and Numbers, is earlier or later than Deuteronomy. The answer to this question turns almost wholly on archæological inquiries, for there is, perhaps, no *quite* conclusive reference to the Elohistic record in the prophets before the Exile, or in Deuteronomy itself. And here arises the great dispute which divides critics, and makes our whole construction of the origin of the historical books uncertain. The Levitical laws give a graduated hierarchy of priests and Levites; Deuteronomy regards all Levites as at least possible priests. Round this difference, and points allied to it, the whole discussion turns. We know, mainly from Ezek. xliv., that before the Exile the strict hierarchical law was not in force, apparently never had been in force. But can we suppose that the very idea of such a hierarchy is the latest point of liturgical development? If so, the Levitical element is the latest thing in the Pentateuch, or, in truth, in the historical series to which the Pentateuch belongs; or, on the opposite view, the hierarchic theory existed as a legal programme long before the Exile, though it was fully carried out only after Ezra. As all the more elaborate symbolic observances of the ritual law are bound up with the hierarchial ordinances, the solution of this problem has issues of the greatest importance for the theology as well as for the literary history of the Old Testament.

Fusion of several elements into one narrative.

And now a single word on the way in which these various elements, mirroring so many sides of the national life, and dating from so various ages, came to be fused into a single history, and yet retained so much of their own identity. The Semitic genius does not at all lie in the direction of organic structure. In architecture, in poetry, in history, the Hebrew adds part to part instead of developing a single notion. The temple was an aggregation of small cells, the longest Psalm is an acrostic, and so the longest Biblical history is a stratification and not an organism. This process was facilitated by the habit of anonymous writing, and the accompanying lack of all notion of anything like copyright. If a man copied a book it was his to add and modify as he pleased, and he was not in the least bound to distinguish the old from the new. If he had two books before him to which he attached equal worth, he took large extracts from both, and harmonized them by such additions or modifications as he felt to be necessary. But in default of a keen sense for organic unity very little harmony was sought in points of internal structure, though great skill was often shown, as in the book of Genesis, in throwing the whole material into a balanced scheme of external arrangement. On such principles minor narratives were fused together one after the other, and at length in exile a final redactor completed the great work, on the first part of which Ezra based his reformation, while the latter part was thrown into the second canon The curious combination of the functions of copyist and author which is here presupposed did not wholly disappear till a pretty late date; and where, as in the books of Samuel, we have two recensions of the text, one in the Hebrew and one in the Septuagint translation, the discrepancies are of such a kind that criticism of the text and analysis of its sources are separated by a scarcely perceptible line.

Poetical Books.—The origin of some leading peculiarities of Hebrew poetry has been recently referred by Assyriologists to Accadian models; but however this may be, the key to the whole development of the poetical literature of Israel is found in the same psychological characteristics of the race which are impressed on the vocabulary and grammatical structure of the language. The Hebrew tongue is sensuous, mobile, passionate, almost incapable of expressing an abstract idea, or depicting a complex whole with repose and symmetry of parts, but fit to set forth with great subtilty individual phases of nature or feeling. It is the speech of a nation whose naturally quick perceptions minister to an emotional temperament and an imperious will, which subordinates knowledge to action and desire, and habitually contemplates the universe through the medium of personal feeling or practical purpose. To speak with the philosophers, the Hebrew character is one of predominant subjectivity, eager to reduce everything to a personal standard, swift to seize on all that touches the feelings or bears directly on practical wants, capable of intense effort and stubborn persistence where the motive to action is personal affection or desire, but indisposed to theoretical views, unfit for contemplation of things as they are in themselves apart from relation to the thinker. In the poetry of such a nation the leading current must necessarily be lyrical, for the lyric is the natural vehicle of intense and immediate personal feeling. The earliest Hebrew poems are brief, pregnant expressions of a single idea, full of the fire of passion, full, too, of keen insight into nature, in her power to awake or sustain human emotion; but recording this insight not with the pictorial fulness of western art, but in swift, half-formed outlines, in metaphor piled on metaphor, without regard to any other principle of proportion or verisimilitude than the emotional harmony of each broken figure with the dominant feeling. Such a poetry could not but find its highest scope in the service of spiritual religion. The songs in Exod. xv. and Judg. v. prove the early origin of a theocratic poetry; but the proper period of Hebrew psalmody begins with David, and its history is practically the history of the Psalter. Here, as in the case of the historical books, we have to begin by questioning the tradition contained in the titles, which ascribe seventy-three Psalms to David, and besides him name as authors Asaph, the sons of Korah, Solomon, Moses, Heman, Ethan. Again the tendency is to refer as much as possible to familiar names. There is no reason to believe that any title is as old as the Psalm to which it is prefixed, and some titles are certainly wrong; for example, the author of the elegy on Saul and Jonathan could not possibly have written Ps. lxxxvi., which is a mere cento of reminiscences from other poems. On the other hand the titles are not purely arbitrary. They seem to supply useful hints as to the earlier collections from which our present Psalter was made up. The Korahite and Asaphite Psalms may probably have been derived from collections in the hands of these families of singers; and the so-called "Psalms of David" were very likely from collections which really contained poems by David and other early singers. The assertion that no Psalm is certainly David's is hyper-sceptical, and few remains of ancient literature have an authorship so well attested as the 18th or even the 7th Psalm. These, along with the indubitably Davidic poems in the book of Samuel, give a sufficiently clear image of a very unique genius, and make the ascription of several other poems to David extremely probable. So, too, a very strong argument claims Psalm ii. for Solomon, and in later times we have sure landmarks in the psalms of Habakkuk (Hab. iii.)

Characteristics of Hebrew poetry.

Landmarks in the history of Hebrew lyric—the Psalms.

David.

and Hezekiah (Isa. xxxviii.) But the greater part of the lyrics of the Old Testament remain anonymous, and we can only group the Psalms in broad masses, distinguished by diversity of historical situation and by varying degrees of freshness and personality. As a rule the older Psalms are the most personal, and are not written for the congregation, but flow from a present necessity of individual (though not individualistic) spiritual life. This current of productive psalmody runs apparently from David down to the Exile, losing in the course of centuries something of its original freshness and fire, but gaining a more chastened pathos and a wider range of spiritual sympathy. Psalm li., obviously composed during the desolation of the temple, marks, perhaps, the last phase of this development. The epoch of the return was still not without poetic freshness, as some of the so-called Songs of Degrees (Pilgrim-songs?) prove. But on the whole the Psalms of the second temple are only reflections of old ideas, cast mainly in directly liturgical form, or at least embodying the experience of the nation rather than of the individual. The date of the latest Psalms is much disputed. Most lines of evidence suggest that the collection was complete before the latest books of the canon were written, but many expositors find in individual Psalms (44, 74, 79, 83, &c.) clear traces of the Maccabee age.

Parallelism or sense-rhythm.

Through the whole period of Hebrew lyric, represented not only by the Psalter, but by the Lamentations, traditionally ascribed to Jeremiah, and by various scattered pieces in Prophets (*e.g.*, Isa. xii.) and in historical books (*e.g.*, Num. xxi. 17; 1 Sam ii.), there is little change in form and poetic structure. From first to last the rhythm consists not in a rise and fall of accent or quantity of syllables, but in a pulsation of sense, rising and falling through the parallel, antithetic, or otherwise balanced members of each verse. (So-called *Hebrew Parallelism;* better *Sense-rhythm.*) Beyond this one law of rhythm, which is itself less an artificial rule than a natural expression of the principle, that all poetic utterance must proceed in harmonious undulation, and not in the spasm of unmodulated passion, the Hebrew poet was subject to no code of art, though strophical arrangements, sometimes marked by a refrain, are not uncommon; while poems of acrostic structure (alphabetic Psalms) are found not exclusively in the most recent literature (Ps. ix., x. form a single undoubtedly old acrostic). The later are on the whole longer than the earlier poems. But this is due not to increased constructive power, but to a diffuser style, a less vigorous unity of feeling and thought, and a tendency to ring many variations on one key. A wider range of artistic power appears in the Song of Solomon, a lyrical drama, in which, according to most critics, the pure love of the Shulamite for her betrothed is exhibited as victorious over the seductions of Solomon and his harem. As the motive of the piece is political as well as ethical, it is most naturally assigned to the early period of the northern kingdom.

Lyrical drama.

Poetical wisdom—the Mashal.

The remaining poetical books of the Old Testament belong to a different category. Unfit for abstract speculation, valuing no wisdom that is not practical, and treasuring up such wisdom in sententious rhythmical form,—enforced by symbol and metaphor, and warm with the breath of human interest,—the Hebrew is a poet even in his philosophy. Side by side with the ode the earliest Hebrew literature shows us the Mashal, or *similitude*, sometimes in the form of biting epigram (Num. xxi., 27 *ff.*) or sarcastic parable (Judg. ix. 8; 2 Kings xiv. 8), sometimes as the natural vehicle of general moral teaching. The greatest name in the early proverbial wisdom of Israel is that of Solomon (1 Kings iv. 32), and beyond doubt many of his aphorisms are to be found in the book of Proverbs. Yet this book is not all Salomonic. The last two chapters are ascribed to other names, and part of the collection was not put in shape till the time of Hezekiah (xxv. 1), who can have had no infallible criterion of authorship by Solomon, and must not be credited with critical intentions. In truth, the several sections of the book are varied enough in colour to make it plain that we have before us the essence of the wisdom of centuries, while the introductory address in chapters i.–ix. shows how a later age learned to develop the gnomic style, so as to fit it for longer compositions. The fundamental type of Hebrew philosophy remains, however, unchanged, even in the book of Ecclesiastes, which bears every mark of a very late date, long after the Exile. On the other hand, a fresh and creative development, alike in point of form and of thought, is found in the book of Job, which, in grandly dramatic construction, and with wonderful discrimination of character in the several speakers, sums up the whole range of Hebrew speculation on the burning question of Old Testament religion, the relation of affliction to the justice and goodness of God and to the personal merit and demerit of the sufferer. Like the other noblest parts of the Old Testament, the book of Job has a comparatively early date. It was known to Jeremiah, and may be plausibly referred to the 7th century B.C.

Proverbs.

Ecclesiastes.

Job.

In the book of Job we find poetical invention of incidents, attached for didactic purposes to a name apparently derived from old tradition. There is no valid *a priori* reason for denying that the Old Testament may contain other examples of the same art. The book of Jonah is generally viewed as a case in point. Esther, too, has been viewed as a fiction by many who are not over sceptical critics; but on this view a book which finds no recognition in the New Testament, and whose canonicity was long suspected by the Christian as well as by the Jewish Church, must sink to the rank of an apocryphal production.

Jonah.

Esther.

Freedom taken by copyists.

In the poetical as in the historical books anonymous writing is the rule; and along with this we observe great freedom on the part of readers and copyists, who not only made verbal changes (*cf.* Ps. xiv. with Ps. liii.), but composed new poems out of fragments of others (Ps. cviii. with lvii. and lx.) In a large part of the Psalter a later hand has systematically substituted Elohim for Jehovah, and an imperfect acrostic, like Ps. ix., x., cannot have proceeded in its present form from the first author. Still more remarkable is the case of the book of Job, in which the speeches of Elihu quite break the connection, and are almost universally assigned to a later hand.

Literary activity of prophets.

Prophetical Books.—We have already seen that the earliest prophecies of certain date are of the 8th century, though there is a probability that Joel flourished in the 9th century, in the reign of Joash of Judah, and that the opening verses of Amos are cited from his book. On the other hand, the old school of prophecy, whose members from Samuel to Elisha were men of action rather than of letters, was not likely to leave behind it any written oracles. The prophets generally spoke under the immediate influence of the spirit or "hand of Jehovah." What they wrote was secondary, and was, no doubt, greatly abridged. The most instructive account of the literary activity of a prophet is given in Jer. xxxvi. Jeremiah did not begin to write till he had been more than twenty years a prophet. Some prophetic books, like that of Amos, seem to have been composed at one time and with unity of plan. Other prophets, like Isaiah, published several books summing up portions of their ministry. In one or two cases, especially in that of Ezekiel, the prophet writes oracles which were apparently never spoken. Before the Exile there was circulation of individual prophetic books, and earlier prophets quote from their predecessors. But the task of

collecting and editing the remains of the prophets was hardly undertaken till the commencement of the second canon; and by this time, no doubt, many writings had been lost, others were more or less fragmentary, and the tradition of authorship was not always complete.

Prophecies are often anonymous.

It was, indeed, more important to have an oracle authenticated by the name of its author than to know the writer of a history or a Psalm, and many prophets seem to have prefixed their names to their works. But other prophecies are quite anonymous, and prophets who quote earlier oracles never give the author's name. (A famous case occurs, Isa. xv., xvi., where in xvi. 13, for *since that time* read *long ago*.) Now all the remains of prophecy, whether provided with titles or not, were ultimately arranged in four books, the fourth of which names, in separate titles, twelve authors; while the first three books are named after Isaiah, Jeremiah, Ezekiel, and actually mention no other names in the titles of the several prophecies of which they are made up. But is it safe to assume that every anonymous prophecy in these books must be by the author of the next preceding prophecy which has a title? Certainly any such assumption can only be provisional, and may be overthrown by internal evidence.

Internal evidence of date.

But internal evidence of date, it is said, cannot apply to prophetic books in which the author looks in a supernatural way into the future. The value of this argument must be tested by looking more closely at the actual contents of the prophetic books. The prophecies contain—1*st*, reproof of present sin; 2*d*, exhortation to present duty; 3*d*, encouragement to the godly and threatening to the wicked, based on the certainty of God's righteous purpose. In this last connection prophecy is predictive. It lays hold of the ideal elements of the theocratic conception, and depicts the way in which, by God's grace, they shall be actually realized in a Messianic age, and in a nation purified by judgment and mercy. But in all this the prophet starts from present sin, present needs, present historical situations. There is no reason to think that a prophet ever received a revelation which was not spoken directly and pointedly to his own time. If we find, then, that after the prophecy of Zechariah i.–viii., which is complete in itself, there begins at ch. ix. a *new* oracle, quite distinct in subject and style, which speaks of an alliance between Judah and Israel as a thing subsisting in the prophet's own time, which knows no oppressor later than Assyria and Egypt, and rebukes forms of idolatry that do not appear after the Exile;—if, in short, the whole prophecy becomes luminous when it is placed a little after the time of Hosea, and remains absolutely dark if it is ascribed to Zechariah, we are surely entitled to let it speak for itself. When the principle is admitted other applications follow, mainly in the book of Isaiah, where the anonymous chapters, xl.–lxvi., cannot be understood in a natural and living way except by looking at them from the historical stand-point of the Exile.

Titles.

Then arises a further question, whether all *titles* are certainly authentic and conclusive; and here, too, it is difficult to answer by an absolute affirmative. For example, in Isa. xxx. 6, the title, "The burden of the beasts of the south," interrupts the connection in a most violent way. This is not a solitary instance, but on the whole the titles are far more trustworthy in the prophecies than in the Psalms, and partly on this account, but mainly from the direct historical bearing of prophetic teaching, we can frame a completer history of written prophecy than of any other part of Old Testament literature.

Northern prophets.

We have, on the one hand, a series of prophets—Amos, Hosea, and the anonymous author of Zech. ix.–xi.—who preached in the northern kingdom, but are not descendants of the school of Elisha, which had so decayed under court favour from the dynasty of Jehu, that Amos had to be sent from the wilderness of Judah to take up again the forgotten word of the Lord. In Judah proper we have the great Assyrian prophets,

Assyrian prophets.

Isaiah with his younger contemporary Micah, the powerful supporters of the reformation of Hezekiah, labouring one in the capital, the other in the country district of the Philistine border. To the Assyrian period belongs also Nahum, who wrote, perhaps, in captivity, and foretold the fall of Nineveh. Then comes Zephaniah about the time of the Scythian ravages, followed by the prophets of the Chaldean period;

Chaldean period.

first Habakkuk and then Jeremiah and Ezekiel, men of a heavier spirit and less glowing poetic fire than Isaiah, no longer upholding the courage of Judah in the struggle with the empire of the East, but predicting the utter dissolution of existing things, and finding hope only in a new covenant —a new theocracy. In the period of Exile more than one anonymous prophet raised his voice; for not only the "Great Unnamed" of Isa. xl.–lxvi., but the authors of other Babylonian prophecies, are probably to be assigned to this time. In the new hope of deliverance the poetic genius, as well as the spiritual insight of prophecy, awakes to fresh life, and sets forth the mission of the new Israel to carry the knowledge of the Lord to all nations. But the spirit of the new Jerusalem had little in common with these aspirations, and in Haggai, Zechariah, and Malachi,

The latest prophets.

prophecy retains not much of its old power except an uncompromising moral earnestness. The noble poetry of the old prophets, which even in the time of Ezekiel had begun to give way to plain prose, finds no counterpart in these latest oracles; and imaginative power is shown, where it still exists, in the artificial structure of symbolic visions. No important new ideas are set forth, and even the tone of moral exhortation sometimes reminds us more of the rabbinical maxims of the fathers in the Mishna, than of the prophetic teaching of the 8th century. And as if the spirit of prophecy foresaw its own dissolution, Malachi looks not to the continued succession of prophets, but to the return of Elijah as the necessary preparation for the day of the Lord.

Daniel.

In this sketch of the prophetic writings we find no place for the book of Daniel, which, whether composed in the early years of the Persian empire, or, as modern critics hold, at the time of the Maccabee wars, presents so many points of diversity from ordinary prophecy as to require entirely separate treatment. It is in point of form the precursor of the apocalyptic books of post-canonical Judaism, though in its intrinsic qualities far superior to these, and akin to the prophets proper.

Further History of the Old Testament Canon in the Jewish Church.—Under this head we confine ourselves to points which lead up to the reception of the Old Testament by Christendom. These are mainly two:—(1), the history of the Hebrew text, which we now possess only in the recension established by Jewish scribes at a time later than the Christian era; (2), the history of those versions which arose among Jews, but have influenced Christendom.

The consonantal text.

The Text of the Old Testament.—Semitic alphabets have no full provision for distinguishing vowels, and the oldest writing, before orthography became fixed, was negligent in the use even of such vowel-letters as exist. For a long time, then, not only during the use of the old Phœnician character, but even after the more modern square or Babylonian letters were adopted, the written text of the Bible was *consonantal only*, leaving a certain scope for variety of pronunciation and sense. But even the consonantal text was not absolutely fixed. The loose state of the laws of spelling and the great similarity of several letters made errors of copying frequent. The text of Micah, for example, is often unintelligible, and many hopeless errors are older than the oldest versions.

Plurality of recensions.

But up to the time of the Alexandrian version, MSS. were in circulation which differed not merely by greater or less accuracy of transcription, but by presenting such differences of recension as

could not arise by accident. The Greek text of Jeremiah is vastly different from that of the Hebrew Bible, and it is not certain that the latter is always best. In the books of Samuel the Greek enables us to correct many blunders of the Hebrew text, but shows at the same time that copyists used great freedom with details of the text. For the Pentateuch we have, in the copies of the Samaritans, a third recension, often but not always closely allied to the Greek. The three recensions show important variations in the chronology of Genesis; and it is remarkable that the *Book of Jubilees*, a Jewish treatise, which cannot be much older than the Christian era, perhaps not much older than the destruction of the Jewish state, sometimes agrees with the Samaritan or with the Alexandrian recension. Up to this time, then, there was no absolutely received text.

Received or Massoretic text. But soon after the Christian era all this was changed, and by a process which we cannot follow in detail, a single recension became supreme. The change was, no doubt, connected with the rise of an overdrawn and fantastic system of interpretation, which found lessons in the smallest peculiarity of the text; but Lagarde has made it probable that no critical process was used to fix the standard recension, and that all existing MSS. are derived from a single archetype, which was followed even in its marks of deletion and other accidental peculiarities. (Lagarde, *Ammerkn. zur griech. Uebersetzung der Prov.*, 1863, p. 1; *cf.* Nöldeke in Hilgenfeld's *Zeitschr.*, 1873, p. 445.) Then the received text became the object of farther care, and the Massorets, or "possessors of tradition" with regard to the text, handed down a body of careful directions as to the true orthography and pronunciation. The latter was **Vowel-points.** fixed by the gradual invention of subsidiary marks for the vowels, &c., an invention developed in slightly divergent forms in the Babylonian and Palestinian schools of Jewish scholarship. The vowel-points were not known to Jerome, but the system was complete before the 9th century, presumably several hundred years before that time. All printed Bibles follow the Western punctuation, but old Karaite MSS. with the Babylonian vowels exist, and are now in course of publication. It is from the Massoretic text, with Massoretic punctuation, that the English version and most Protestant translations are derived. Older Christian versions, so far as they are based on the Hebrew at all (Jerome's Latin, Syriac), at least follow pretty closely the received consonantal text.

Jewish Versions.—Versions of the Old Testament became necessary partly because the Jews of the Western Dispersion adopted the Greek language, partly because even in Palestine the Old Hebrew was gradually supplanted by Aramaic. **Septuagint** The chief seat of the Hellenistic Jews was in Egypt, and here arose the Alexandrian version, commonly known as the Septuagint or Version of the LXX., from a fable that it was composed, with miraculous circumstances, by seventy-two Palestinian scholars summoned to Egypt by Ptolemy Philadelphus. In reality there can be no doubt that the version was gradually completed by several authors and at different times. The whole is probably older than the middle of the 2d century B.C. We have already seen that the text that lay before the translators was in many parts not that of the present Hebrew The execution is by no means uniform; and, though there are many good renderings, the defects are so numerous that the Greek-speaking Jews, as well as the large section of the Christian church which long depended directly or indirectly on this version, were in many places quite shut out from a right understanding of the Old Testament. Nevertheless, the authority of the version was very great, its inspiration was often asserted, and its interpretations exercised a great influence on Jewish and Christian thought, though among the Jews it was to a certain extent displaced by the version of the proselyte Aquila (2d century of our era), which followed with slavish exactness the letter of the Hebrew text.

Among the Jews who spoke Aramaic, translations into **Targums.** the vernacular accompanied, instead of supplanting the use of the original text, which was read and then orally paraphrased in the synagogues by interpreters or Methurgemanim, who used great freedom of embellishment and application. This practice naturally led to the formation of written Targums, or Aramaic translations, which have not, however, reached us in at all their earliest form. It used, indeed, to be supposed that the simple and literal Targum of Onkelos on the Pentateuch was earlier than the time of Christ But recent inquirers have been led to see in it, and in the linguistically cognate Targum on the Prophets (Targum of Jonathan), products of the Babylonian schools, in which the freedom of the early paraphrastic method was carefully avoided. Upon this view the date of these Targums is some centuries after the Christian era. On the other hand, an older style of paraphrase is preserved in the Palestinian Targums, which nevertheless contain in their present form elements later than the Babylonian versions. The Targum of Pseudo-Jonathan on the Pentateuch is apparently the latest form of the free Palestinian version, full of legendary adornments and other additions to the text. Other fragments of Palestinian translation, known as the Jerusalem Targum, and referring to individual passages of the Pentateuch and Prophets, probably represent an earlier stage in the growth of the Aramaic versions. There are also Targums on the Hagiographa, which, however, have less importance, and do not seem to have had so changeful a history. The Targums as a whole do not offer much to the textual critic. They are important, partly from the insight they give into an early and in part pre-Christian exegesis, partly from their influence on later Jewish expositors, and through them on Christian versions and expositions. In some cases the literal or Babylonian Targums have a text differing from the Massoretic. But it is not unlikely that if we had a satisfactory text of the Targums (towards which almost nothing has hitherto been done), these variations would find their explanation in the Eastern text and the Assyrian punctuation.

NEW TESTAMENT.—*Relation of the Earliest Christianity to the Literary and Intellectual Activity of the Age.*—In the **The scribes.** literature of Palestine at the time of Christ we distinguish a learned and a popular element. The learned class or scribes were busy on their twofold structure of Halacha, or legal tradition and inference, supplementing and "hedging in" the Pentateuchal law, and Haggada, or fantastic exegesis, legendary, ethical, or theosophic, under which the religious directness of the Old Testament almost wholly disappeared. The popular religious literature of the day **Popular apocalyptic.** seems again to have been mainly apocalyptic. (See APOCALYPTIC LITERATURE.) The people never wearied of these mysterious revelations couched in strange symbolic and enigmatic forms, and placed in the mouths of ancient patriarchs and worthies, which held forth golden visions of deliverance and vengeance in a shape which, because crasser and earthlier, was also more palpable than the spiritual hopes of the old prophets. Beyond the limits of Palestine thought took a wider range. In adopting the Greek **Hellenism.** language the Hellenistic Jews had also become open to the influences of foreign speculation, and the schools of Alexandria, whose greatest teacher, Philo, was contemporary with the foundation of Christianity, had in great measure exchanged the faith of the Old Testament for a complicated system of metaphysico-theological speculations upon the Absolute Being, the Divine Wisdom, the Logos, and the like, which by the aid of allegorical interpretation were made to appear as the true teaching of Hebrew antiquity.

To these currents of thought the relation of the earliest Christianity, entirely absorbed in the one great fact of the manifestation of God in Christ crucified, risen, and soon to return in glory, was for the most part hostile, when it was not merely superficial. With the spirit of the scribes Jesus had openly joined issue. In the legal tradition of the elders he saw the commandment of God annulled (Matt. xv.) It was His part not to destroy but to fill up into spiritual completeness the teaching of the old dispensation (Matt. v.); and herein He attached himself directly to the prophetic conception of the law in Deuteronomy (Matt. xxii. 37, *ff.*) And not only in His ethical teaching but in His personal sense of fellowship with the Father, and in the inner consciousness of His Messianic mission, Jesus stood directly on the Old Testament, reading in the Psalms and Prophets, which so vainly exercised the unsympathetic exegesis of the scribes, the direct and unmistakable image of His own experience and work as the founder of the spiritual kingdom of God (*cf.* especially, Luke xxiv. 25, *ff.*) Thus Jesus found His first disciples among men who were strangers to the theological culture of the day (Acts iv. 13), cherishing no literature but the Old Testament witness to Christ, and claiming no wisdom save the knowledge of Him. At first, indeed, the church at Jerusalem was content to express its new life in simple exercises of faith and hope, without any attempt to define its relation to the past dispensation, and without breaking with the legal ordinances of the temple. But the spread of Christianity to the Gentiles compelled the principles of the new religion to measure themselves openly with the Judaism of the Pharisees. In the heathen mission of Paul the ceremonial law was ignored, and men became Christians without first becoming proselytes. The stricter Pharisaically-trained believers were horror-stricken. The old apostles, though they could not refuse the right hand of fellowship to workers so manifestly blessed of God as Paul and Barnabas, were indisposed to throw themselves into the new current, and displayed considerable vacillation in their personal conduct. Paul and his associates had to fight their own battle against the constant efforts of Judaizing emissaries, and the rabbinical training acquired at the feet of Gamaliel enabled the apostle of the heathen to meet the Judaizers on their own ground, and to work out the contrast of Christianity and Pharisaism with a thoroughness only possible to one who knew Pharisaism from long experience, and had learned the gospel not from the tradition or teaching of men but by revelation of Jesus Christ (Gal. i. 12).

Jesus and the scribes.

Paul and the Judaizers.

The relation of the first Christians to the current apocalyptic was of a different kind. The Messianic hopes already current among the first hearers of the gospel were unquestionably of apocalyptic colour. And though the contents of Christian hope were new, and expressed themselves in a revival of prophetic gifts (1 Cor. xii. 10; Acts xi. 27, &c), it was not a matter of course that apocalyptic forms should be at once dropped, especially as Old Testament prophecy itself had inclined in its later stages towards an increasing concreteness in delineating the Messianic kingdom, and so had at least formed the basis for many apocalyptic conceptions. The apocalyptic books continued to be read, as appears from the influence of the book of Enoch on the epistle of Jude; and after the new spirit of prophecy had died away a Christian apocalyptic followed the Jewish models But the way in which a genuine Christian prophecy, full of "the testimony of Jesus" (Rev. xix 10), retained not a little of the apocalyptic manner (mainly, it is true, in dependence on the book of Daniel), appears clearly in the Revelation of John, which, whether we accept the prevalent tradition of its apostolic authorship, or, with some ancients and many moderns, ascribe it to a different John, is at least an undisputed monument of the prophecy of the apostolic age (according to modern critics, *earlier* than the fall of Jerusalem).

Christian prophecy and apocalyptic.

The influence on Christianity of Hellenistic philosophy, and, in general, of that floating spirit of speculation which circulated at the time in the meeting-places of Eastern and Western thought, was for the most part later than the New Testament period. Yet the Alexandrian education of a man like Apollos could not fail to give some colour to his preaching, and in the epistle to the Hebrews, whose author, a man closely akin to Paul, is not a direct disciple of Jesus (Heb. ii. 3), the theological reflection natural to the second generation, which no longer stood so immediately under the overpowering influence of the manifestation of Christ, is plainly affected in some points by Alexandrian views. In the case of other books the assertion of foreign speculative influences is generally bound up with the denial of the authenticity of the book in question. That the gospel of John presents a view of the person of Christ dependent on Philonic speculation is not exegetically obvious, but is simply one side of the assertion that this gospel is an unhistorical product of abstract reflection. In the same way other attacks on the genuineness of New Testament writings are backed up by the supposed detection of Orphic elements in the epistle of James, and so forth.

Hellenistic thought in the church

Motives and Origin of the first Christian Literature.—We have seen that the earliest currents of Christian life and thought stood in a very secondary relation to the intellectual activity of the period. The only books from which the Apostolic Church drew largely and freely were those of the Old Testament, and the Christian task of proclaiming the gospel was not in the first instance a literary task at all. The first writings of Christianity, therefore, were of an occasional kind. The care of so many churches compelled Paul to supplement his personal efforts by epistles, in which the discussion of incidental questions and the energetic defence of his gospel against the Judaizers is interwoven with broad applications of the fundamental principles of the gospel to the whole theory and practise of Christian life. In these epistles, and generally in the teaching of Paul and his associates, Christian thought first shaped for itself a suitable literary vehicle. It was in Greek that the mission to the Gentiles was carried on, for that language was everywhere understood. Already in the mouths of Hellenistic Jews and in the translation of the Old Testament the κοινή, or current Greek of the Macedonian period, had been tinctured with Semitic elements, and adapted to express the ideas of the old dispensation. Now a new modification was necessary, and soon in the circle of the Pauline churches specifically Christian ideas became inseparably bound up with words which to the heathen had a very different sense Whether the epistolary way of teaching was used upon occasion by the older apostles before the labours of Paul is not clear; for most scholars have declined to accept the ingenious view which sees in the epistle of James the earliest writing of the New Testament. The other epistles are certainly later, and the way in which several of them are addressed, not to a special community in reference to a special need but to a wide circle of readers, seems to presuppose a formed custom of teaching by letter which extended from Paul not only to so like-minded a writer as the author of Hebrews (Apollos or Barnabas ?) but to the old apostles and their associates.

The epistles.

Besides epistles we have in the New Testament a solitary book of Christian prophecy and a fourfold account of the gospel history, with a continuation of the third gospel in the Acts of the Apostles. The origin and mutual relations of the gospels form at the present moment the field of numerous controversies which can only be dealt with in separate articles. We must here confine ourselves to one or two points of general bearing.

Synoptic gospels.

Jewish disciples were accustomed to retain the oral teaching of their masters with extraordinary tenacity and verbal exactness of memory (Mishna, *Aboth*, iii. 8; *Edaioth*, i. 3), and so the words of Jesus might for some time be handed down by merely oral tradition. But did the gospel continue to be taught orally alone up to the time when the extant gospels were written? or must we assume the existence of earlier evangelical writings forming a link between oral tradition and the narratives we now possess? The earliest external evidence on this point is given in the prologue to Luke's gospel, which speaks of many previous essays towards a regularly digested evangelical history on the basis of the tradition (whether exclusively oral or partly written is not expressed) of eye-witnesses who had followed the whole course of Christ's ministry. It seems to be implied that if the eye-witnesses wrote at all, they, at least so far as was known to Luke, did not compose a regular narrative but simply threw together a mass of reminiscences. This understanding of the words of the evangelist agrees very well with the uniform tradition of the old church as to the second gospel, viz., that it was composed by Mark from material furnished by Peter. This tradition goes back to Papias of Hierapolis, about 150 A.D., but it is a fair question whether the second gospel as we have it is not an enlarged edition of Mark's original work. On the other hand ecclesiastical tradition recognizes the apostle Matthew as the author of the first gospel, but does so in a way that really bears out the statements of Luke. For the tradition that Matthew wrote the first gospel is always combined with the statement that he wrote in Hebrew (Aramaic). But from the time of Erasmus the best Greek scholars have been convinced that the gospel is not a translation. Either, then, the whole tradition of a directly apostolic Aramaic gospel is a mistake, caused by the existence among the Judaizing Christians in Palestine of an apocryphal "Gospel according to the Hebrews," which was by them ascribed to Matthew, but was, in fact, a corrupt edition of our Greek gospel; or, on the other hand, what Matthew really wrote in Aramaic was different from the book that now bears his name, and only formed an important part of the material from which it draws. The latter solution is naturally suggested by the oldest form of the tradition; for what Papias says of Matthew is that he wrote τὰ λόγια, *the oracles*,—an expression which, though much disputed, seems to be most fairly understood not of a complete gospel but of a collection of the words of Christ. And if so, all the earliest external evidence points to the conclusion that the synoptical gospels are non-apostolic digests of spoken and written apostolic tradition, and that the arrangement of the earlier material in orderly form took place only gradually and by many essays. With this the internal evidence agrees. The three first gospels are often in such remarkable accord even in minute and accidental points of expression, that it is certain either that they copied one another or that all have some sources in common. The first explanation is inadequate, both from the nature of the discrepancies that accompany the agreement of the three narratives, and from the impossibility of assigning absolute priority to any one gospel. For example, even if we suppose that the gospel of Mark was used by the other two authors, or conversely that Mark was made up mainly from Matthew and Luke, it is still necessary to postulate one or more earlier sources to explain residuary phenomena. And the longer the problem is studied the more general is the conviction of critics, that these sources cannot possibly have been merely oral.

Papias.

It appears from what we have already seen, that a considerable portion of the New Testament is made up of writings not directly apostolical, and a main problem of criticism is to determine the relation of these writings, especially of the gospels, to apostolic teaching and tradition. But behind all such questions as the relative priority of Matthew or of Mark, the weight to be assigned to the testimony of Papias, and so forth, lies a series of questions much more radical in character by which the whole theological world is at present agitated Can we say of all the New Testament books that they are either directly apostolic, or at least stand in immediate dependence on genuine apostolic teaching which they honestly represent? or must we hold, with an influential school of modern critics, that a large proportion of the books are direct forgeries, written in the interest of theological tendencies, to which they sacrifice without hesitation the genuine history and teaching of Christ and his apostles? There are, of course, positions intermediate to these two views, and the doctrine of tendencies is not held by many critics even of the Tübingen school in its extreme form. Yet, as a matter of fact, every book in the New Testament, with the exception of the four great epistles of St Paul, is at present more or less the subject of controversy, and interpolations are asserted even in these. The details of such a controversy can only be handled in separate articles, but a few general remarks may be useful here.

Tübingen school.

External evidence.

The arguments directed by modern critics against the genuineness or credibility of New Testament books do not for the most part rely much on external evidence. Except in one or two cases (particularly that of 2d Peter) the external evidence in favour of the books is as strong as one can fairly expect, even where not altogether decisive. We shall see when we come to speak of the canon that, towards the close of the 2d century, the four gospels, the Acts, thirteen epistles of Paul, the first epistles of Peter and John, and the book of Revelation, were received in the most widely separated churches with remarkable unanimity. Before this time the chain of evidence is less complete. All our knowledge of the period that lies between the apostles and the great teachers of the Old Catholic Church towards the close of the 2d century is fragmentary. We possess but scanty remains of the literature, and the same criticism which seeks to bring down many New Testament books into this period questions the genuineness of many of the writings which claim to date from the first half of the 2d century, and so are appealed to by conservative writers. But on the whole, what evidence does exist is of a kind to push back all the more important writings to an early date. The gospel of John, for example, is one of the books which negative critics are most determined in rejecting. Yet the fairest writers of the school (Hilgenfeld, Keim) admit that it was known to Justin Martyr in the middle of the 2d century, though they think that besides our four gospels he had a fifth of apocryphal character. But references of an earlier date can hardly be denied; and the gospel may be traced almost to the beginning of the century by the aid of fragments of the Gnostic Basilides and of the epistles of Ignatius. The Tübingen school, indeed, maintain that the fragments preserved by Hippolytus are not from Basilides, but from a later writer of his school, and utterly reject the Ignatian epistles. But it cannot be said that they have proved their case beyond dispute. They have at most shown that, if the gospel *must on other grounds* be taken as spurious, the external evidence may be pushed aside as not absolutely insuperable. On the other hand they try to bring positive proof that certain books were unknown in circles where, if genuine, they must have circulated. But such a negative is in its very nature difficult to prove. Probably the strongest argument of the kind is that brought to show that Papias did not know the gospel of John. But we know Papias only through Eusebius; and though the latter

The fourth gospel.

is careful to mention all references to disputed books, it does not appear that it was part of his design to cite testimony to a book so universally allowed as John's gospel. And Papias does give testimony to the first epistle of John, which is hardly separable from the gospel. On the whole, then, we repeat that, on the most cardinal points, the external evidence for the New Testament books is as strong as can fairly be looked for, though not, of course, strong enough to convince a man who is sure *a priori* that this or that book is unhistorical and must be of late date.

The strength of the negative critics lies in internal evidence. And in this connection they have certainly directed attention to real difficulties, many of which still await their explanation. Some of these difficulties are not properly connected with the Tübingen position. The genuineness of 2d Peter, which, indeed, is very weakly attested by external evidence, was suspicious even to Erasmus and Calvin, and no one will assert that the Pauline authorship of 1st Timothy is as palpable as that of the epistle to the Romans. So, again, it is undeniable that the epistle to the Colossians and the so-called epistle to the Ephesians differ considerably in language and thought from other Pauline epistles, and that their relation to one another demands explanation. But in the Tubingen school all minor difficulties, each of which might be solved in detail without any very radical procedure, are brought together as phases of a single extremely radical theory of the growth of the New Testament. The theory has two bases, one philosophical or dogmatical, the other historical; and it cannot be pretended that the latter basis is adequate if the former is struck away. Philosophically the Tubingen school starts from the position so clearly laid down by Strauss, that a miraculous interruption of the laws of nature stamps the narrative in which it occurs as unhistorical, or, at least, as more cautious writers put the case, hampers the narrative with such extreme improbability that the positive evidence in favour of its truth would require to be much stronger than it is in the case of the New Testament history. The application of this proposition makes a great part of the narrative of the Gospels and Acts appear as unhistorical, and therefore late; and the origin of this late literature is sought by regarding the New Testament as the monument of a long struggle, in the course of which an original sharp antagonism between the gospel of Paul and the Judaizing gospel of the old apostles was gradually softened down and harmonized. The analysis of the New Testament is the resurrection of early parties in the church, each pursuing its own tendency by the aid of literary fiction. In the genuine epistles of Paul on the one hand, and in the Revelation and some parts of Matthew on the other, the original hostility of ethnic and Jewish Christianity is sharply defined; while after a series of intermediate stages the Johannine writings present the final transition in the 2d century from the contests of primitive Christianity to the uniformity of the Old Catholic Church. This general position has been developed in a variety of forms, more or less drastic, and is supported by a vast mass of speculation and research; but the turning points of the controversy may, perhaps, be narrowed to four questions—(1.) Whether in view of Paul's undoubted conviction that miraculous powers were exercised by himself and other Christians (1 Cor. xii 9, *f.*; 2 Cor. xii. 12) the miracle criterion of a secondary narrative can be maintained? (2.) Whether the book of Acts is radically inconsistent with Paul's own account of his relations to the Church at Jerusalem, and whether the antithesis of Peter and Paul is proved from the epistles of the latter, or postulated in accordance with the Hegelian law of advance by antagonism? (3.) Whether the gospel of John is necessarily a late fiction, or does not rather supply in its ideal delineation of Jesus a necessary supplement to the synoptical gospels which can only be understood as resting on true apostolic reminiscence? (4.) Whether the external evidence for the several books and the known facts of church history leave time for the successive evolution of all the stages of early Christianity which the theory postulates?

The Tübingen theory.

The Christian Canon of the Old and New Testaments.—We have already seen that the Apostolic Church continued to use as sacred the Hebrew Scriptures, whose authority derived fresh confirmation from the fulfilment of the prophecies in Christ. The idea that the Old Testament revelation must now fall back into a secondary position as compared with inspired apostolic teaching was not for a moment entertained. Still less could the notion of a body of New Testament Scriptures, of a collection of Christian writings, to be read like the Old Testament in public worship and appealed to as authoritative in matters of faith, take shape so long as the church was conscious that she had in her midst a living voice of inspiration. The first apostolic writings were, as we have seen, occasional, and it was not even matter of course that every epistle of an apostle should be carefully preserved, much less that it should be prized above his oral teaching. Paul certainly wrote more than two epistles to the Corinthians, and even Papias is still of opinion, when he collects reminiscences of apostolic sayings from the mouths of the elders, that what he reads in books cannot do him so much good as what he receives "from a living and abiding voice." Nay, the very writers who are the first to put Old and New Testament books on a precisely similar footing (*e.g.*, Tertullian) attach equal importance to the tradition of churches which had been directly taught by apostles, and so were presumed to possess the "rule of faith" in a form free from the difficulties of exposition that encumber the written word. In the first instance, then, the authoritative books of the Christian church were those of the Old Testament; and in the time of the apostles and their immediate successors it was the Hebrew canon that was received. But as most churches had no knowledge of the Old Testament except through the Greek translation and the Alexandrian canon, the Apocrypha soon began to be quoted as Scripture. The feeling of uncertainty as to the proper number of Old Testament books which prevailed in the 2d century is illustrated by an epistle of Melito of Sardis, who journeyed to Palestine in quest of light, and brought back the present Hebrew canon, with the omission of the book of Esther. In the 3d century Origen knew the Hebrew canon, but accepted the Alexandrian additions, apparently because he considered that a special providence had watched over both forms of the collection. Subsequent teachers in the Eastern Church gradually went back to the Hebrew canon (Esther being still excluded from full canonicity by Athanasius and Gregory of Nazianzus), distinguishing the Alexandrian additions as ἀναγιγνωσκόμενα—books used for ecclesiastical lessons. In the Western Church the same distinction was made by scholars like Jerome, who introduced for merely ecclesiastical books the somewhat incorrect name of Apocrypha; but a laxer view was very prevalent and gained ground during the Middle Ages, till at length, in opposition to the Protestants, the Council of Trent accepted every book in the Vulgate translation as canonical.

Christian canon—Old Testament.

We turn now to the New Testament collection. The idea of canonicity—the right of a book to be cited as Scripture—was closely connected with regular use in public worship, and so the first step towards a New Testament canon was doubtless the establishment of a custom of reading in the churches individual epistles or gospels. The first beginnings of this custom must have been very early. The reference to Luke in 1 Tim. v. 18 is disputed, and

New Testament canon.

2 Pet. iii. 16 is usually taken as one of many arguments against the genuineness of that epistle; but a citation from Matthew is certainly referred to as Scripture in the epistle of Barnabas. But such recognition of an individual gospel is a long way removed from the recognition of an apostolic canon. The apostolic writings continued to be very partially diffused, and readers used such books as they had access to, often failing to distinguish between books of genuine value and worthless forgeries. For most readers were very uncritical, and there was an enormous floating mass of spurious and apocalyptic literature, including recensions of the gospel altered by heretical parties to suit their own views. It was perhaps in contest with the heretics of the 2d century that the necessity of forming a strict list of really authoritative writings came to be clearly felt; and it is remarkable that heretics, generally hostile to the Old Testament, seem to have been among the first to form collections of Christian writings for themselves. Thus Marcion, in the middle of the 2d century, selected for himself on dogmatical grounds ten Pauline epistles, and a gospel which seems to have been based on Luke. Up to this time perhaps no formal canon of sacred writings had been put forth by the Catholic Church. But in the second half of the century the notion of an authoritative New Testament collection appears in full development, and there is an amount of agreement as to the contents of the canon, which implies that, in spite of the loose way in which apocryphal books circulated side by side with genuine works, the church had no great difficulty in drawing a sharp line between the two classes when this was felt to be necessary. At the time of the great teachers of the close of the 2d century (Irenæus, Tertullian, Clement) we find a twofold collection, *the Gospel* and *the Apostles*. The Gospel comprises the four evangelists; and this number was already so absolutely fixed as to admit of no further doubt.

Quite beyond dispute were also the main books of the *Apostolicon*, the Acts, thirteen epistles of Paul, 1st Peter, 1st John, and the Apocalypse. The Muratorian fragment which contains a list twenty or thirty years older than the 3d century omits 1st Peter, but adds Jude, 2d and 3d John (?), and (as a disputed book) the Apocalypse of Peter. The Shepherd of Hermas might also be read, but it is pointed out that it is of quite recent date and not of prophetic or apostolic authority. From this time forward, then, the controversy is narrowed to a few books, occupying a middle position between the large mass of our present New Testament, which was already beyond dispute, and the spurious literature which was quite excluded from ecclesiastical use. Absolute uniformity was not at once attainable, for various churches had quite independent usages; and, as we see from the Muratorian canon, a book might receive a certain ecclesiastical recognition without being, therefore, viewed as strictly canonical. This dubious margin to the canon was of very uncertain limits, and Clement of Alexandria still uses many apocryphal books which found no acknowledgment in other parts of the church. Gradually the list of books which have even a disputed claim to authority is cut down. In the time of Eusebius the Shepherd of Hermas was still read in some churches, and several other books—the Epistle of Barnabas, the Acts of Paul, the Revelation of Peter, the Teachings of the Apostles—appear as controverted writings. But all these are plainly on the verge of rejection, while, on the other hand, 2d and 3d John, Jude, James, and 2d Peter are gradually gaining ground. This process continued to go on without interruption till at length the whole class of disputed books (*antilegomena*) melted away, and only our present canon was left on the one hand, and books of no authority or repute upon the other. Thus the Council of Laodicea was able wholly to forbid the ecclesiastical use of uncanonical books (360 A.D.) and the only uncertain point remaining in the tradition of the Eastern Church was the position of the Apocalypse, which had gradually fallen into suspicion, and was not fully reinstated till the 5th century. The Western Church, on the other hand, was long dubious as to the epistle to the Hebrews, which was received without hesitation in the East, as the Apocalypse continued to be in the West. The age of Augustine and Jerome saw the close of the Western canon.

Antilegomena.

Transmission and Diffusion of the Bible in the Christian Church before the Invention of Printing.

Under this head we have to speak—1st, of the transmission of the original text; 2d, of the ancient versions.

Text of O. T.

1. THE ORIGINAL TEXT—*Old Testament.*—The rapid spread of Christianity among the Gentiles of the West made Greek the sacred language of Christendom. Not only is Greek the language of the New Testament, but it was in the Septuagint version that the Old Testament was first circulated in the most important Gentile churches. Hebrew was almost unknown even to learned Christians, and in fact the current (Jewish as well as Christian) doctrine of the inspiration of the Septuagint, and a suspicion that the Hebrew text had been falsified by the Jews, made the study of the original appear unprofitable. A juster view of the value of Hebrew studies was formed by the two greatest scholars of the patristic period, Origen and Jerome. But the Septuagint continued to enjoy an authoritative place in the Eastern Church; and the Latin Church, though it finally adopted Jerome's translation from the Hebrew in place of the older translation from the Greek, was not led by this change to take any interest in further study of the original. The Hebrew Bible continued to be the peculiar possession of the Jews, of whose labours in fixing and transmitting a standard text we have already spoken. It was not till the beginning of the 16th century that Christian scholars began to take a lively interest in the "Hebrew verity;" and what has been done since that time to repair so many centuries of neglect belongs to the history of the printed text or of exegesis.

Text of N. T.—external features.

New Testament.—The original copies of the New Testament writings were probably written on papyrus rolls, and were so soon worn out by frequent use, that we do not even possess any historical notice of their existence. They must, however, have been written in *uncial* or large capital letters, without division of words or punctuation, without accents, breathings, &c., and probably without any titles or subscriptions whatever. The earliest transcripts comprised only portions of the New Testament, the gospels being oftenest copied, and the Pauline oftener than the catholic epistles. Even after the canon became fixed, MSS. of the whole New Testament, or of the whole Greek Bible, were comparatively rare. The order of the several books was not quite fixed; but the catholic epistles generally followed the book of Acts. It may also be noted that in the oldest MSS. the epistle to the Hebrews precedes the pastoral epistles. In course of time various changes were introduced in the externals of the written text. Parchment and vellum took the place of papyrus, and form the material of the oldest extant copies. The uncial character held its ground till about the 10th century, when the use of a *cursive* or running hand became general. Attempts to indicate the punctuation go back as far as the 4th or 5th century. The oldest MSS. use for this purpose an occasional simple point, or a small blank space in the line. Another system was to write the text in short lines (στίχοι) accommodated to the sense. The author of this *stichometry* was Euthalius of Alexandria in the second half of the 5th century, who applied it to the epistles and Acts. The same plan was afterwards extended to the gospels; but vellum was too costly to allow of its general adoption. The present system of punctuation was first used in printed books. Breathings and accents were not in common use down to the end of the 7th century; but occasional traces of them seem to occur considerably earlier.

Another device for the more convenient use of the New Testament was the division of the text into sections of various kinds. The gospels were divided by Ammonius of Alexandria (220 A.D.) into short chapters (Ammonian sections, κεφάλαια), constructed to facilitate the comparison of corresponding passages of the several gospels. These sections are marked on the margin of most MSS. from the 5th century onwards; and in general a reference is also given to the so-called canons of Eusebius, which are a kind of index to the sections, enabling the reader to find the parallel passages. Another division of the gospels into larger sections (τίτλοι, breves) is also found in MSS. of the 5th century, and a similar division of the other books into chapters (κεφάλαια) came into use not much later. The chapters of the Acts and the catholic epistles were the work of Euthalius. Our present chapters are much later. They were invented by Cardinal Hugo of S. Carus in the 13th century, were first applied to the Latin Bible, and are still unknown in the

Eastern Church. The present system of verses first appears in the edition printed by Robert Stephens in the year 1551.

The titles and subscriptions of the New Testament books are another point on which a succession of changes has taken place. The oldest MSS. have much shorter titles than those which the English version adopted from the later Greek text; and the subscriptions, with their would-be historical information, are not only late, but worthless. Those appended to the epistles of St Paul are attributed to Euthalius.

Various readings. More important than these external matters are the variations which in course of time crept into the text itself. Many of these variations are mere slips of eye, ear, memory, or judgment on the part of a copyist, who had no intention to do otherwise than follow what lay before him. But transcribers, and especially early transcribers, by no means aimed at that minute accuracy which is expected of a modern critical editor. Corrections were made in the interests of grammar or of style, slight changes were adopted in order to remove difficulties, additions came in, especially from parallel narratives in the gospels, citations from the Old Testament were made more exact or more complete. That all this was done in perfect good faith, and simply because no strict conception of the duty of a copyist existed, is especially clear from the almost entire absence of deliberate falsification of the text in the interests of doctrinal controversy. To detail all the sources of various readings would be out of place; it may suffice to mention, in addition to what has been already said, that *glosses*, or notes originally written on the margin, very often ended by being taken into the text, and that the custom of reading the Scriptures in public worship naturally brought in liturgical additions, such as the doxology of the Lord's Prayer; while the commencement of an ecclesiastical lesson torn from its proper context had often to be supplemented by a few explanatory words, which soon came to be regarded as part of the original.

Up to a certain point the various readings due to so many different causes constantly became more and more numerous; but the number of independent readings which could arise and be perpetuated was limited by various circumstances. A general similarity necessarily prevailed in associated groups of copies, which were either derived from the same archetype, or written by the same copyist, or corrected by comparison with a single celebrated MS. Causes such as these, combined with local peculiarities of style and taste, and with the fact that the New Testament, like Christianity itself, was sent forth from central mother churches to newly-formed communities all around, gave a decided local colouring to the text current in certain regions; so that we are still able to speak in a general way of an Alexandrian, a Western, a Byzantine, and perhaps also (with Tischendorf) of an Asiatic text. But of course no ancient local text remained uninfluenced by copies from other regions. The comparison of copies became more and more extended in range as the church grew and consolidated into a homogeneous form; and though old readings, which had obtained a firm hold in certain communities, were not easily eradicated, it at length became almost impossible for any important new error to escape detection. Most variations of any consequence which are found in existing MSS. are known to be as old as the 4th century, and other readings existed then which no MS. is known to contain.

The variations of early copies were most completely smoothed into uniformity in the later Byzantine MSS., after the Mahometan conquest had overthrown Greek learning in Syria and Egypt. The scribes of Constantinople spent great pains on the text in accordance with their own notions of what was proper, and gave it a form which is certainly smoother, correcter, and more uniform than that of older MSS. But precisely these peculiarities show that this late recension is remote from the original shape of the New Testament writings, and compel us to seek the true text by study of early MSS., especially of the still existing uncial copies.

The MSS. The manuscripts are of six classes, containing respectively the gospels, the Acts with the catholic epistles, the Pauline epistles, the Apocalypse, the ecclesiastical lessons from the gospels, the lessons from the Acts and epistles. Copies belonging to the last two classes are called lectionaries, and lectionaries of the gospels are called evangelistaria. Each MS. is referred to by critics by a special mark. Uncial MSS. are denoted by a capital letter, A standing for the Codex Alexandrinus, B for the Vaticanus, and so on. Cursives and lectionaries are denoted by Arabic numerals. It is to be observed that the same letter in a different part of the New Testament does not necessarily refer to the same MS. Thus Cod. D of the gospels and Acts is the Codex Bezæ, but D of the Pauline epistles is the Claromontanus. If we reckon fragments, the number of uncial MSS. is 56 of the gospels, 14 of the Acts, 6 of the catholic epistles, 15 of the Pauline epistles, 5 of the Apocalypse. But many of these are extremely short fragments. The number of cursives and lectionaries is enormous, so that altogether there are nearly a thousand MSS. for the gospels, and as many more for the rest of the New Testament. Not nearly all the cursive copies have been thoroughly examined, and most of them have small value, though some comparatively recent MSS. are important from the fact that they represent an ancient text. Lectionaries, even when uncial, are little esteemed by most critics. Græco-Latin codices which have the Greek and Latin in parallel columns were formerly suspected of correcting the Greek text by the Latin, but their value is now generally recognized.

Uncial copies. The oldest copies of the Greek Testament are the Codex Sinaiticus (ℵ) and the Codex Vaticanus (B), both of the 4th century. Next in age come the Alexandrian manuscript (A) and the Codex Ephraemi (C), both of which are referred to the 5th century. All of these copies were originally complete Bibles, with the old as well as the New Testament. ℵ is still complete as regards the New Testament; A and B have lacunæ; C is very imperfect, and barely legible, the ancient writing having been almost removed by a mediæval scribe to make way for the writings of Ephraem Syrus. ℵ, A, B, C, are the four great first-rate uncials, and will be found more fully described in separate articles. Besides these there are one or two fragments as old as the 5th century (I, I^b, T).

A quite peculiar place is held by the Græco-Latin Codex Bezæ at Cambridge (D), which dates from the 6th century, but presents a text full of the most singular interpolations. The other uncials of the gospels are less important, either from their fragmentary state or from the character of their text. The later uncials are hardly more valuable than good cursives.

The most important MS. of the Acts, in addition to those already mentioned, is E, the Codex Laudianus, Græco-Latin of the 6th century, in the Bodleian at Oxford. For the Pauline epistles we may mention D, or Codex Claromontanus, at Paris, also Græco-Latin of the 6th century, and H, or Codex Coislinianus, of the same century, of which there are 12 leaves at Paris and 2 at St Petersburg. Uncial authority is most scanty for the Apocalypse, for which the Vaticanus is defective. B of the Apocalypse is an uncial of the 8th century.

Greek versions. 2. The Christian Versions.—We have seen that the early church adopted the LXX., not so much in the character of a version, as in that of an authoritative original. Although several attempts were made in the 2d century of our era to produce a better Greek rendering of the Old Testament, not one of these seems to have had its origin in the Catholic Church. Aquila was a Jew, whose closely verbal rendering was designed to serve the subtilties of Rabbinic exegesis. Symmachus and Theodotion were probably Ebionites. The former was an excellent master of Greek, who happily corrected many clumsy renderings of the LXX., but inclined too much to paraphrase, and to the obliteration of characteristic figures and bold expressions. Theodotion made less extensive changes, and aimed only at necessary corrections. His rendering of Daniel was so manifest an improvement that it entirely displaced the old version, and is still regularly printed as part of the LXX.

Origen's Hexapla. In the Christian Church the importance of these new versions, and the unsatisfactory condition of the LXX.—which, apart from its original defects, had been much corrupted in successive transcriptions—were first clearly set forth by Origen in his Hexaplar edition of the Old Testament. This great work takes its name from the six columns in which it was arranged, containing respectively the Hebrew in the proper character, the same in Greek letters, the versions of Aquila, Symmachus, and Theodotion, and a text of the LXX., partly corrected by comparison of MSS., partly emended by recourse to the Hebrew. The variations of several less important versions were also noted. The complete Hexapla was too huge a work to be transcribed and circulated as a whole. It lay in the library at Cæsarea, and was only occasionally consulted by scholars; but the column containing Origen's emended text of the LXX. was published in separate transcripts by Eusebius and Pamphilus, and attained so great a circulation that in the Palestinian churches, as we learn from Jerome, it quite displaced the older text. In composing his Hexaplar text, Origen was careful to distinguish his own improvements from the original LXX. by the use of asterisks and other marks. In later copies these marks were unfortunately often omitted. The Hexaplar text became mixed up with the true LXX., and the modern critic is sometimes tempted to forget how much the Eastern Church owed to this first attempt to go back to the Hebrew Old Testament, in his impatience at the obliteration by the adoption of Hexaplar corrections of important divergences of the LXX. from the Massoretic text. Our knowledge of the other columns of Origen's great edition is fragmentary, and is derived partly from citations in ancient authors, partly from notes in MSS. of the Hexaplar LXX., or of the Syriac translation of it composed by Paul of Tela (616 A.D.) The best collection of these fragments is that edited by Field (*Origenis Hexaplorum quæ supersunt*, Oxford, 1867-1875).

The first origin of translations of the Christian Scriptures into the vernacular of non-Hellenic churches is involved in much obscurity. Apart from the probable existence of early Aramaic gospels, there is no sure trace of a Christian literature in any other tongue than Greek till late in the 2d century. Even in the churches of Gaul, Greek was the recognized language of Christian authorship. In Rome the literary use of Greek extended into the 3d century; and in the earliest days of the Roman Church, Greek was the language of public worship. Even in remoter districts the demand

for a vernacular Bible can hardly have come from the educated and reading classes, but arose rather from the custom of reading lessons from Scripture in the congregation. The earliest Christian translations are the Peshito or "Simple" version in Syria, and the Old Latin in Africa, monuments of the early vigour of two great churches on the eastern and western outskirts of Hellenic culture.

Syriac versions.

It is scarcely probable that either of these versions is older than the middle of the 2d century. The Syriac, which claims to be first considered, was already an old version, containing obsolete expressions, in the time of S. Ephraem, who died 373 A.D. Internal marks of antiquity are found in the relation of the Old Testament to a very early Jewish exegesis, and especially in the omission from the New Testament of 2 Peter, 2 and 3 John, Jude, and Revelation. On the other hand, there is no certain reference to this version by authors earlier than Ephraem; and the data afforded by the history of the canon, and by a comparison of the earliest remains of Syriac literature—the hymns of Bardesanes, who died about 225—are not sufficient to supply the lack of direct information. Some critics still date the version from the beginning of the 2d century, while others would bring it down into the 3d. Even the close of the 3d century has been named; but this view rests on the unlikely supposition that the omission of five New Testament books was due to later theological influences, and was not an original peculiarity of the version. The translation is, on the whole, excellent. The Old Testament is taken from the Hebrew, and, though sometimes dependent on Jewish exegesis, and in other parts strongly influenced by the LXX., is decidedly superior to the Targums. The Peshito was the received version in all branches of the much-divided Syrian churches. But it did not stand alone. The Hexaplar version of Paul of Tela, and the slavishly literal Philoxenian (508 A.D.—revised a century later by Thomas of Harkel), were presumably designed in the service of Biblical criticism. More obscure is the origin and purpose of the fragmentary version of the gospels published by Cureton in 1858, and by him supposed to be older than the Peshito.

Latin versions.

In the history of the Old Latin version almost nothing is certain, save that it originated in Africa, before the time of Tertullian, and that it assumed such Protean shapes in the hands of transcribers that it is to this day uncertain whether several distinct versions are not included in the general name of the Old Latin. Jerome, indeed, speaks only of great variations between copy and copy; but Augustine tells us that the "Itala" is to be preferred to the other Latin interpretations. Hence MSS. of the Old Latin are often called copies of the Itala; but in truth no one knows what the Itala is, for it is mentioned only by Augustine, and by him only once.

A version which at best was a rude and over-literal rendering of the Greek Bible, in an unpolished provincial dialect, and which had not even that fixed form which is so necessary in a Bible for ecclesiastical use, could not continue to serve the needs of the great Latin Church; and towards the close of the 4th century a work of revision was undertaken at the instance of Damasus, bishop of Rome, by Jerome, the most learned of the Western doctors. Jerome began by correcting the New Testament, making only such changes as seemed absolutely imperative. In the Old Testament he first revised the Psalter after the LXX., producing the version known as the Roman Psalter from its adoption in the Roman liturgy. A second revision, based on the Hexaplar text, forms the Gallican Psalter, long used in Gaul and other churches beyond the Alps. Then Jerome proceeded to revise other books on the basis of the Hexaplar Greek; but, finding this half-measure unsatisfactory, he finally rendered the Old Testament directly from the Hebrew. The work was completed 405 A.D., and though often dependent on Aquila, and especially on Symmachus, it bears high witness to the scholarship of the author, and is perhaps the best of the ancient versions. In spite of its merits the new version was much attacked, and made way in public estimation by very slow degrees. It was not till the 9th century that the Old Latin was entirely superseded in the Roman Church, and the circulation of the old and new versions side by side was long a fertile source of corruptions in the text of both. At length the complete supremacy of Jerome's Latin was marked by the transference to it of the name of the *Vulgate Version*, which in older times was given to the LXX.

Other Eastern versions.

The Egyptian versions (Memphitic in the dialect of lower Egypt, Thebaic or Sahidic for upper Egypt) supplied the needs of the only great Christian population of the early church which was not able to use the Greek, the Latin, or the Syriac. The most recent inquirers are disposed to believe that Egypt received the Bible in the vernacular almost as soon as Syria. The version was taken from the Greek, which was also the source of various later translations—the Ethiopic, the Armenian (5th century), the Georgian (6th century), the Slavonic (9th century)—fruits of the gradual diffusion of Christianity in the remotest regions of the ancient world. The Gothic version of Ulfilas—the earliest written monument of the Teutonic languages—is of the 4th century, and was also from the Greek. Only fragments of this translation remain to us, mainly in the famous silver-lettered MS. of the 5th or 6th century (*Codex Argenteus*) in the library of Upsal.

Thus far the history of the versions records the triumphs of Christianity. The Arabic versions, on the contrary, owe their origin to the spread of Islam, when the language of the conquering Saracens displaced the ancient dialects of Syria and Egypt. This change did not diminish the authority of the old ecclesiastical versions, or displace them from their position in the services of the church. The edification of the unlearned was secured by reading the lessons in the vulgar tongue, as well as in Syriac or Coptic; and, accordingly, the numerous Christian Arabic versions are mainly taken not from the original tongues, but from the versions whose use they were designed to supplement. In like manner the rise of the New-Persian language and literature produced a Persian version of the Syriac New Testament. Of parts of the Old Testament there are Arabic and Persian translations directly from the Hebrew, but these are the work of Jewish scholars. The Arabic versions of the Pentateuch and Isaiah, by R. Saadias Gaon, in the 10th century, are among the most important monuments of ancient Jewish learning.

Later Western versions.

In the West as in the East the disintegration of the Roman empire was associated with the rise of new national dialects, and Latin ceased to be understood by the laity. But the Roman Church was too intent on the preservation of her homogeneous organization, her visible unity of worship, to allow the vulgar tongues to supplant the old liturgical language, or even to introduce a bilingual service. The use of the Bible in a form intelligible to the illiterate was shifted from the sphere of public worship to that of private edification and instruction; and for the latter purpose the necessities of a barbarous age seemed to demand explanatory paraphrases, Bible narratives in metre, and the like, rather than literal renderings of the whole Scriptures. Thus, in the Anglo-Saxon Church, Caedmon's poetical version of the Bible history dates from 664 A.D., while the earliest prose translations of parts of the Latin Bible (gospels, psalms, &c.) do not seem to be older than the 8th century. In Germany, in like manner, metrical versions of the gospel are among the earliest attempts to convey the Bible to the people. Ottfrid's harmony of the gospels in High German, and the poem called *Hêliand* (Saviour), in Old Saxon, date from the 9th century; and the prose translation of the so-called Gospel Harmony of Tatian —from the Latin of Victor of Capua—belongs to the same age. A complete and literal translation of the Vulgate existed in Germany perhaps as early as the beginning of the 14th century. Among nations whose speech was descended from the vulgar Latin, the work of translation naturally began later. The earliest remains of Romance versions are thought to be as old as the 11th century; but the work of translation assumed important dimensions mainly in connection with the spirit of revolt against the Church of Rome which rose in the 12th and 13th centuries. The study of the Bible in the vulgar tongue was a characteristic of the Cathari and Waldenses, and the whole weight of the church's authority was turned against the use of the Scriptures by the laity. The prohibition of the Bible in the vulgar tongue, put forth at the Council of Toulouse in 1229, was repeated by other councils in various parts of the church, but failed to quell the rising interest in the Scriptures. In England and in Bohemia the Bible was translated by the reforming parties of Wyclif and Huss; and the early presses of the 15th century sent forth Bibles, not only in Latin, but in French, Spanish, Italian, German, and Dutch.

The Printed Text.

Printed Hebrew Bibles.

Though the Latin Bible was the first book printed, the original text was for some time neglected. The Jews of Italy led the way with several editions of parts of the Old Testament, commencing with the Psalter of 1475. The beautiful edition of Soncino (1488) was the first complete Hebrew Bible, and was soon followed by the edition of Brescia, used by Luther (1494). At length Christians interested themselves in the work. The Antwerp printer, Daniel Bomberg, established a Hebrew press in Venice, from which he sent forth a series of Bibles and other books. The famous Rabbinical Bible of 1517, edited by Felix Pratensis, a converted Jew, is known as the first Bomberg Bible, and is especially valuable for the text of the Targums, which it prints in parallel columns with the Hebrew. The second Rabbinical Bible of Bomberg was edited by R. Jacob Chayim (who also became a Christian), and contains the first printed edition of the Massora, with a text carefully corrected in accordance with Massoretic precepts. This edition at once attained a great reputation. It was several times reprinted, and most subsequent editions are directly or indirectly dependent on it. The only early edition which rivals its fame is the Complutensian Polyglott, published at Alcala in 1517, at the expense of Cardinal Ximenes. The Hebrew of this polyglott exhibits a peculiar text, independent of the Italian editions. Later editions of the Hebrew Bible present little or no advance on the early prints; and most recent editions are decidedly inferior. Of Hebrew Bibles, with various readings from MS. authority, the best known are Kennicott's (Oxford, 1776, 1780) and De Rossi's (Parma, 1784–1798). The latter collection is by far the best, but neither has done much for the improvement of the text. In fact the differences between really good MSS. are

generally very minute; and where the current text is corrupt it is not from MSS., but from the versions, or from conjecture, that help must be sought. On the other hand, a more accurate edition of the Massoretic text is certainly wanted. But such an edition must pay special regard to vowel points and accents, which Kennicott and De Rossi neglect, and must consult MSS. of the Massora as well as of the text. The most valuable edition which notes variations not affecting the consonantal text is the Mantuan Bible of 1742, 1744, with the notes of Norzi (R. Jedidiah Solomon of Norcia). The best recent texts are S. Baer's Leipsic editions of Genesis (1869), Psalms (1861), and Isaiah (1872). Among easily accessible editions of the whole Old Testament, those of Jablonsky (Berlin, 1699) and J. H. Michaelis (Halle, 1720) have the best reputation.

Printed text of New Testament. The Greek New Testament was first printed in the Complutensian Polyglott (1514), but a delay in the publication enabled Froben of Basel to preoccupy the market with an edition hastily prepared by Erasmus from very recent codices. In subsequent editions a good many changes were made, partly after the Complutensian text, and in the third edition (1522) the spurious passage, 1 John v. 7, appeared for the first time. But it was still a recent and therefore an unsatisfactory text that was represented, and this radical defect was not corrected by the editors who followed Erasmus, though some of them, and notably Th. Beza, possessed, and to some extent used, better MSS. than Erasmus consulted. Their beauty and convenience, rather than the merit of their text, procured a great currency for the editions of Robert Stephens (*O mirificam* editions, 1546, 1549; royal edition, 1550), and his text of 1550, or the Elzevir text of 1621, which, though mainly based on Beza, is very nearly identical with the other, came to be regarded as the "received text," which subsequent editors were long afraid to change. But materials for a better text were gradually accumulated by Walton in the London Polyglott (1657), Curcellæus (1658), Fell (1675), and above all by John Mill in his great edition of 1707. These labours were viewed with much jealousy by the hyper-orthodox; and even as late as 1751, Wetstein, after long and most valuable studies, could find a publisher only on consideration that his amendments on the received editions should not stand in the text. Some important steps, however, were taken in the interval between Mill and Wetstein. Bentley sketched in 1720 the plan of an edition which should restore the text of the 4th century; and Bengel in 1734 actually published an amended text, though readings which had not been given in any previous edition were admitted only in the Apocalypse. Bengel was the first who classed MSS. under families, as Asiatic and African respectively. The next great critical editor after Bengel and Wetstein was J. J. Griesbach, whose chief edition appeared 1796, 1806. Griesbach gave an exaggerated importance to the doctrine of families of MSS.; and his edition was constructed on the principle of adhering to the received text, unless the reasons to the contrary were irresistible; but his industry and critical skill give him a very high place among editors. Griesbach was followed by the Roman Catholic Scholz, whose labours were more pretentious than valuable; and at length the great critic Lachmann (1842, 1850) threw aside all traditional respect for the received text, and sought to restore the text of the 4th century by the aid of a very small number of select MSS., together with the Latin versions as given in the oldest copies, and the citations of the earliest fathers. The idea was fruitful, though the material employed was too scanty. Since Lachmann published his edition our knowledge of the most ancient authorities has been greatly increased. New MSS. have been added, notably Tischendorf's ℵ; and the MSS. formerly known have been edited or collated with much greater accuracy. The most distinguished labourers in this work were Tischendorf and Tregelles. In addition to numerous editions and collations of ancient copies, Tischendorf put forth a series of critical editions, of which the eighth (Leipsic, 1865-1872) contains the completest critical commentary yet published. The great edition of Tregelles (1857-72) rests exclusively on the most ancient authority, resembling Lachmann's work in conception, though using much more copious materials. This edition, as well as Tischendorf's VIII., lacks the *prolegomena*, both editors having been struck down by paralysis before their work was complete.

Recent versions. The recent versions, subsequent to the invention of printing and the revived study of the original tongues, demand a word in conclusion. New Latin versions naturally accompanied many of the early editions of the original text. Thus Erasmus gave many corrections of the Vulgate in his Greek Testament, the Complutensian gives an interlinear version of the LXX., the Genoa Polyglott Psalter of 1516 gives renderings both of the Hebrew and of the Chaldee. Even such works as these, designed as they were for scholars, gave offence from their appearance of undermining the authority of the Vulgate; and it was the Reformation, in its revolt against mere human authority, that first demanded open circulation of vernacular versions from the original tongues. From the time of Luther's version (New Testament, 1522; complete Bible, 1534) we may distinguish four classes of versions.

1st, Versions adopted by Protestant countries or churches. Such are Luther's Bible in Germany; the Dutch Bible of the Commission of the Synod of Dort, 1637; the English Authorized Version of 1611; the Genevan French Bible, formed by successive revisions of Olivetan's version of 1535; the Danish of 1550, based on Luther, revised in 1607, 1647; the Swedish, 1541. Most of these national Bibles were preceded by earlier Protestant versions, which they supersede. See especially ENGLISH BIBLE. Revisions of the national versions have of late years been undertaken in Norway, Holland, and Germany, as well as in England.

2d, Versions which never held any other place than that of private contributions to Biblical exegesis. Such are—among older works—the Latin Old Testament of Junius and Tremellius, and the New Testament of Beza. These versions belong to the history of exegesis.

3d, Missionary versions.

4th, Roman Catholic versions. The Council of Trent declared the Vulgate version authentic, and forbade interpretations of Scripture not in conformity with the consent of the fathers. Vernacular versions subject to these restrictions were published as the antidote to Protestant Bibles. Such are the Rhemish and Douay versions in English. Other Roman Catholic versions owe their origin to evangelical tendencies within the church. Jansenism, in particular, produced the French version of De Sacy (Mons, 1667), and otherwise stimulated the study of Scripture.

Literature.—Full discussion of some of the topics glanced at in this article must be sought in treatises on individual books or critical problems of the Old and New Testaments. But on most points it will be sufficient to refer to works on Biblical Introduction. The history of this branch of theology with lists of the principal older books—some of which, including the writings of R. Simon, Carpzov, and Eichhorn, are still of value—is given in most recent works on the subject. Of these it may be sufficient to mention for the Old Testament—De Wette's *Einleitung*, rewritten by Schrader (Berlin, 1869), full of condensed information; Bleek's posthumous *Einleitung* (3d edition, 1870), less complete in detail and now rather behind date, but very clear and instructive; Keil's *Einleitung* (3d edition, 1873), which is strictly conservative. The two last are translated. Kuenen's *Historisch-Kritisch Onderzoek*, of which there is a French translation, is very full, but the author has considerably changed his views in the *History of the Religion of Israel* (Haarlem, 1869-70) of which there is an English translation. Ewald's *History of Israel* is important, and is also accessible to the English reader; with it must be taken his books on the *Prophets* and *Poets of the Old Covenant.* Recent English literature on the Old Testament is not very remarkable, but Dr S. Davidson's *Introduction* gives a full account of foreign investigations. The history of the Old Testament in the Christian church has been written by L. Diestel (*Geschichte der Alten Testamentes*, u.s.w., Jena, 1869). For the New Testament, De Wette, Bleek, and Davidson may again be consulted. A very instructive book is Reuss's *Geschichte des Heiligen Schriften Neuen Testaments* (5th edition, Brunswick, 1874). The most recent general work proceeding from the Tübingen school is Hilgenfeld's *Historisch-Kritische Einelitung in das Neue Testament* (Leipsic, 1875). On the canon there are several important works by Credner in German, and an English *History of the Canon of the New Testament*, by Dr Westcott (4th edition, 1875). On the text of the New Testament the English reader may consult Tregelles's volume, contributed to Horne's *Introduction* (1856), and Scrivener's *Plain Introduction to the Criticism of the New Testament* (2d edition, 1874). Le Long's *Bibliotheca Sacra*, continued by Masch (Halle, 1778-1790), gives a full account of editions of the original text and versions, which may be supplemented by reference to De Rossi's *Annales Hebræo-typographici* (*XV. Cent.*, Parma, 1795; *MDI. to MDXL.*, Parma, 1799), and Reuss's *Bibliotheca Novi Testamenti Græci* (Brunswick, 1872). Detailed references to other recent books will be found in the works already cited. (W. R. S.)

BIBLE SOCIETIES, associations for extending the circulation of the Holy Scriptures. For a long period this object has been pursued to a considerable extent by several religious institutions, such as the Society for the Propagation of the Gospel in Wales, formed by the Rev. Thomas Gouge, one of the two thousand ministers ejected by the Act of Uniformity in 1662; the Society for Promoting Christian Knowledge, founded in 1698; the Society for sending Missionaries to India, established in the year 1705 by Frederick IV., King of Denmark, and which numbered among its agents the celebrated missionary, Christian Frederick Schwartz; the Society for Promoting Christian Knowledge in the Highlands and Islands of Scotland, formed in Edinburgh in 1709; the Moravian Missionary Society, founded in 1732; the Book Society for Promoting Religious Knowledge among the Poor, which was formed in London in 1750, and numbered among its earliest friends Dr Doddridge and the Rev. James Hervey; and the Religious Tract Society, founded in 1779. But the first British association which had in view the single purpose of disseminating the Scriptures was the NAVAL AND MILITARY BIBLE SOCIETY, established in the year 1780, which has done immense service to the army and navy of Great Britain. The sphere of its operations, however, was comparatively limited, and in 1804 the BRITISH AND FOREIGN BIBLE SOCIETY, the greatest agency ever devised for the diffusion of the Word of God, was founded. The proposal to institute this association originated with the Rev. Mr Charles of Bala, whose philanthropic labours in Wales were greatly impeded by the scarcity of the Scriptures in the principality, and it was largely fostered at the outset by members of the committee of the Religious Tract Society. The exclusive object of the British and Foreign Bible Society is to promote the circulation of the Scriptures, both at home and abroad, and its constitution admits the co-operation of all persons disposed to concur in its support. The committee of management consist of 36 laymen, 6 of them being foreigners resident in or near the metropolis, and of the remaining 30, one-half are members of the Church of England, and the other half members of other Christian denominations.

The proceedings of this society gave rise to several controversies, one of which related to the fundamental law of the society to circulate the Bible alone without notes or comments. On this ground it was vehemently attacked by Bishop Marsh and other divines of the Church of England, who insisted that the Prayer-Book ought to be given along with the Bible. Another controversy, in which the late Dr Andrew Thomson of Edinburgh took a prominent part, related to the circulation on the Continent, chiefly by affiliated societies, of the Apocrypha along with the canonical books of Scripture. In 1826 it was resolved by the committee that the fundamental law of the society be fully and distinctly recognized as excluding the circulation of the Apocrypha. This step, however, failed to satisfy all the supporters of the society in Scotland, who proceeded to form themselves into independent associations. A third serious controversy by which the society has been agitated, was occasioned by the alleged inaccuracy of some of the translations issued under its authority; and a fourth referred to the admissibility of non-Trinitarians to the privilege of co-operation. The refusal of the society in 1831 to alter its constitution so as formally to exclude such persons, led to the formation of the Trinitarian Bible Society. This has, however, been exceedingly limited in its operations, and the original society stands unrivalled.

By a law of the British and Foreign Bible Society, no translations are adopted or circulated in the languages of the United Kingdom except the Authorized Version. For other countries the best ancient or received versions are printed; and in the case of new translations, every effort is made to ascertain their strict fidelity and general literary merit. Most of the versions for countries not yet enlightened by Christianity are made by resident missionaries; and these the society prints at the instance of the missionary societies for whose use they are chiefly intended. These versions are made, wherever practicable, from the original Hebrew or Greek text. The society has had a share, direct or indirect, in the translation, printing, or distribution of Scriptures in 210 languages or dialects, the number of versions thus printed being 269. Altogether the society has put into circulation nearly 74 million Bibles, Testaments, and Portions (*i.e.*, single books of the Bible); and its expenditure for this purpose has amounted to £7,750,000.

In the course of 1874 there were issued from the society's depôts, at home and abroad, no fewer than 2,619,427 Bibles, Testaments, and Portions. The free income for 1874–75 amounted to £119,093, 7s. 7d.; adding the contributions for special objects, and the proceeds by sale of Scriptures, a total is reached of £222,191, 5s. 6d. The payments for translating, printing, and circulating the Scriptures were only £691 in the first year of the society's existence; while in 1874–75 they were £217,390, 13s. 1d.

Immediately after the foundation of the society an extensive correspondence was opened with ministers and laymen in all parts of the world.

Auxiliary and Branch Societies were gradually formed in every district of the United Kingdom and in the colonies. These became centres whence the Scriptures might be obtained at cost price, and in cases of special need at even less. There are at present in the United Kingdom 4496 auxiliaries and branches, besides 1208 in the British colonies. Many of these are managed by ladies. Juvenile associations have also been organized in many localities.

Agents have been appointed both at home and abroad to investigate local requirements, to supply information for the guidance of the committee, and to suggest the best means of carrying out the great purpose of the society.

Depôts for the sale of Scriptures have likewise been opened in almost every town of England, and in many places abroad.

Colportage is employed to some extent in England, and very largely on the Continent and in India.

Grants to Societies are made on various conditions. When applied for by missionary societies and philanthropic institutions, copies of the Scriptures are supplied very freely; while grants of money and paper are made to other Societies in aid of the translation and printing of the Scriptures, when good reasons are seen for the expenditure.

It may be added that the society does not encourage the *gratuitous* distribution of Bibles and Testaments, except under peculiar circumstances.

The first English New Testament printed by the society was issued in September 1805. Stereotype printing had just been introduced; and this invention, coupled with the society's plan of selling the Scriptures at a very low price, brought about a speedy and general reduction in the price of English Bibles. Besides this indirect benefit which has thus been secured to English readers, the investigations and exertions of the society first revealed, and then relieved, the great scarcity of Bibles which had previously existed. To show what the deficiency was, it may be mentioned that in 1812 inquiry was made into the case of 17,000 families in the metropolis, when it was discovered that half of them did not possess a Bible at all.

The efforts of the society in India are organized upon a scale and with a completeness scarcely rivalled elsewhere. Bible circulation in India owes its origin mainly to the zeal of the Serampore missionaries, especially of Carey, Marshman, and Ward, whose labours had begun shortly before the Bible Society was formed. It was stimulated by the exertions of Dr Claudius Buchanan, and by the establishment of the college at Fort William. Gradually auxiliary societies were formed at important centres—such as Calcutta, Bombay, Madras, Allahabad, &c. One of these auxiliaries alone—that at Madras—circulated in 1874–75 over 120,000 copies, and employed 55 native colporteurs. The assistance afforded by the society to India and Ceylon in grants of money, paper and books—including £27,230 supplied to Dr Carey and his associates—amounts to no less a sum than £361,193.

When the society began to inquire into the state of the Continent, the dearth of Scriptures was found to be greater, if possible, than at home. Thus, in Lithuania, among 18,000 Germans, 7800 Polish, and 7000 Lithuanian families, not a Bible was to be found. One half of the population of Holland appeared to be without the Scriptures. In Poland a Bible could hardly be obtained at any price. In the district of Dorpat (Esthonia), containing 106,000 inhabitants, not 200 Testaments were to be found, and there were Christian pastors who did not possess the Scriptures in the dialect in which they preached. Into Iceland, with a population of 50,000, of whom almost all could read, not above 40 or 50 copies had penetrated; while in Sweden a single auxiliary found 13,900 families totally unprovided.

Such was the state of things abroad when the society was established. Correspondence was at once opened with well-known men like Oberlin Knapp, and Herzog; the society's foreign secretary and agents personally visited the districts, and various subsidiary societies were formed. The highest patronage was often obtained for these, the emperor of Russia, the kings of Prussia, Bavaria, Sweden, and Würtemberg, and many others, entering heartily into the work. Some of the societies thus formed were, however, suppressed through the influence of Rome. More than 15,000,000 copies have been printed by them up to the present time.

Of all the foreign Bible societies, by far the most remarkable was that established in Russia, in the year 1812, under the presidency of Prince Galitzin, and with the direct approval and support of the Emperor Alexander I. An imperial ukase was issued, giving formal sanction to the project; all communities joined to speed it on its way; 289 auxiliaries were rapidly formed; the Scriptures were printed in nearly 30 languages, including Modern Russ; 861,000 copies were circulated; and at the time of its suspension in 1826 it had been aided by the British and Foreign Bible Society to the extent of £16,833.

Besides thus encouraging Bible circulation through friendly counsel and pecuniary aid, the British and Foreign Bible Society has done and is doing a direct work on the Continent, some illustration of which may be gathered from the following particulars:—

The first French Bible printed by the society was prepared for the prisoners of war in 1805. After the peace was concluded, measures were taken to form centres of Bible circulation through the country. As a result of these movements, various Bible societies sprang up. Depôts have also been opened in Paris and many other large towns; and special provision has been made for the provincials of the west, by the preparation of Basque and Breton versions. There have been printed by the society, in the French tongue, upwards of seven and a half million copies of the Scriptures.

In 1835, when Mr W. P. Tiddy went out as agent for the society in Belgium, hardly a Bible was to be found in the country, and evangelistic efforts were rare, through the vehement opposition which they encountered. A staff of colporteurs was appointed, and through their efforts a large supply of Scriptures was distributed. This led to the formation of several Protestant communities.

The society's agent in Germany superintends the movements of between 60 and 70 colporteurs, and reports a yearly circulation of about 300,000 copies. The services rendered during the Franco-Prussian war were so signal as to call forth not only the grateful appreciation of the Germans, but a written acknowledgment from the emperor, who is himself an annual subscriber to the society.

Efforts were made by Dr Pinkerton in 1816 to establish a National Bible Society for Austria; but through the influence of the Pope the emperor was induced to reject the proposal. A new beginning was made in 1850, when in less than two years 41,659 copies of the Scriptures, in German, Bohemian, and Hungarian, were put into circulation. Fresh opposition was, however, soon awakened, and the authorities ordered the whole stock on hand to be withdrawn from the country. In compliance with this order, Mr E. Millard, the society's agent, retired to Prussia, where he laboured for several years with marked success. After a while he was permitted to return to Vienna, and to open depôts at such centres as Pesth, Trieste, Klausenburg, and Prague. By these means, and through a large staff of colporteurs, he has issued during the past ten years 1,250,000 copies.

Very little direct work was done in Italy until the Revolution of 1848. Then the society gladly hailed the opportunity of entering the country; but soon the door was again closed. The Pope issued an encyclical in 1849, in which the condemnation of Bible societies was emphatically repeated. As a consequence, 3000 New Testaments, just printed at Florence, were seized, presses were confiscated, paper and type carried off, and the society's agent compelled to retire. All this is now altered. The headquarters of the society's Italian agency are at Rome, and the Scriptures are distributed from depôts and by colporteurs in all parts of the peninsula.

Little could be done in Spain prior to the Revolution of 1868, which threw open the country and established religious liberty. All available means were then adopted for printing and circulating the Spanish Bible. The issues from the Madrid depôt have exceeded half a million copies, but during the recent civil troubles the movements of the colporteurs have been much restricted.

Between 300,000 and 400,000 copies of the Scriptures have been printed in the Portuguese tongue.

Mr Paterson paid a visit to Sweden in 1809 on behalf of the society, and found the poor almost entirely without the Scriptures. Thus in one diocese 10,000 families were discovered without a Bible in their possession. An agency was established in 1831. Special grants have been made to the army and navy, and for the students in the universities. The total issues since 1832 have been over 20,00,000, and that in a population of less than 4,000,000.

To give even an outline of the work done by the British and Foreign Bible Society in the more remote parts of the world would be to write a volume. All the great missionary societies are its debtors. Its undenominational character has secured what could hardly otherwise have been attained—the use of the same version by missionaries of different churches; and it has often proved a healer and a peace-maker abroad, while it has been a bond of union at home. To the linguist and to the comparative philologist its operations are of intense interest; and the boon conferred on the thought and language of many nations through its versions of the Scriptures is well-nigh inestimable.

The EDINBURGH BIBLE SOCIETY originated in the controversy respecting the circulation of the Apocrypha, and was composed of Protestants professing their belief in the doctrine of the Holy Trinity, and disposed to co-operate in promoting the dissemination of the Scriptures.

The SCOTTISH BIBLE SOCIETY was instituted upwards of forty years ago. At the time of its establishment, the other Bible societies in Scotland employed their funds chiefly in circulating the Scriptures in foreign countries. This association was intended exclusively for the distribution of the Bible at home, and its funds were at first derived from collections made in the parish churches within the Synod of Lothian and Tweeddale.

The Scotch Bible societies were amalgamated in 1861, and took the name of the NATIONAL BIBLE SOCIETY OF SCOTLAND. During the year 1874 the society issued 340,908 Bibles, Testaments, and "Portions," its receipts, including the proceeds of sales, amounting to £26,840.

The first Bible society in America is believed to have been established by a few Baptists in New York in 1804; its object was to purchase and lend Bibles for a month at a time. The PHILADELPHIA BIBLE SOCIETY, which was instituted December 12, 1808, was for some years the only association in the country for the gratuitous distribution of the sacred Scriptures. The AMERICAN BIBLE SOCIETY was formed at New York, May 8, 1817. It has numerous auxiliaries throughout the several states of the Union. In 1875 its income amounted to $577,569. Its issues during that year were 926,900 Bibles and Testaments, and since its formation 31,893,332.

Among other societies may be mentioned the BIBLE TRANSLATION SOCIETY, whose versions embody the views of the Baptists, and the PORTEUSIAN BIBLE SOCIETY (named from Bishop Porteus), for the circulation of Bibles marked so as to show the practical bearing of each chapter.

It is believed that there are altogether about 70 Bible societies in the world. The issues of the 7 leading societies may be summarized as follows:—

The British and Foreign Bible Society	73,750,538
The American Bible Society	31,893,332
The National Bible Society of Scotland	4,563,669
The Prussian Bible Society at Berlin	4,083,413
The Hibernian Bible Society	3,962,581
The Wurtemberg Bible Society	1,279,966
The Netherlands Bible Society	1,258,643
Total	120,792,142

The monopoly of the right to print the Bible in England is still possessed by the Universities of Oxford and Cambridge, and her Majesty's printer for England. But after a controversy, which was carried on for some time with great warmth (1840–41), the prices of the common Bibles and Testaments were greatly reduced, and they have gradually attained their present remarkable cheapness.

In Scotland, on the expiry of the monopoly in 1839, Parliament refused to renew the patent, and appointed a Bible Board for Scotland, with power to grant licences to print the Authorized Version of the Scriptures. This step produced a great reduction in the price of the sacred volume, and its circulation was considerably increased.

BIBLIOGRAPHY

THE term Bibliography has passed through different meanings. The βιβλιόγραφος of the Greeks, like the *librarius* of the Romans, was a mere copyist. When the name *bibliographie* was adopted by the French, it was used, as late as the middle of the last century, to signify skill in deciphering and judging of ancient manuscripts. Its special application to printed books may be said to date from the *Bibliographie Instructive* of De Bure in 1763; not that he appears to have coined the new meaning of the term, but his work first popularized the study which the growth of libraries and the commerce in literature had created.

Bibliography, thus understood, may be defined as the science of books, having regard to their description and proper classification. Viewing books simply as vehicles of learning, it would undoubtedly be correct to extend our inquiry to the period when the only books, so called, were manuscripts. And such is, in fact, the view adopted by bibliographers like Peignot, Namur, and Hartwell Horne. But a survey so extensive is open to practical objections. In the first place, bibliography as a science was unknown until long after printing had laid its first foundations, and indeed made it a necessity, with requirements increasing with the multiplied productions of the press. The materials for comparative study were wanting in an age when books were regarded as isolated treasures, to be bought at prices corresponding with their scarcity. In the second place, the critical study and comparison of ancient manuscripts, their distribution into families deduced from one or more archetypes, and the investigation of ancient systems of writing, embrace a subject so wide in its scope and special in its character, that convenience of treatment, confirmed as it is by the facts of history, would alone suggest the propriety of distinguishing between manuscript and printed bibliography. This distinction it is here proposed to observe, the subject of MSS. being reserved for the article PALÆOGRAPHY, the name which in its maturity it received.

Amid much variety of treatment in detail, two main divisions underlie the general study of bibliography, viz., *material* and *literary*, according as books are regarded with reference to their form or their substance. The former belongs chiefly to the bookseller and book-collector; the latter to the literary man and the scholar. Material bibliography treats of what Savigny terms the "aussere Bücherwesen," or the external characteristics of books, their forms, prices and rarity, the names of the printers, the date and place of publication, and the history of particular copies or editions. It involves a knowledge of typography, not, indeed, as a mechanical process, but in its results, and, in fact, of all the constituent part of books, as a means of identifying particular productions. Its full development is due to the gradual formation of a technical science of books. Considerations of buying and selling, which were first reduced to a system in Holland, and afterwards advanced to their present complete form in France and England, gave an impetus to this branch of bibliography. The growth of private libraries, especially during the last century in France, promoted a passion among rich amateurs for rare and curious books; and literary antiquarians began to study those extrinsic circumstances, apart from the merit of their contents, which went to determine their marketable value, and to reveal the elements of rarity.

Literary, or, as it is sometimes called, intellectual bibliography treats of books by their contents, and of their connection in a literary point of view. It has been subdivided into *pure* and *applied*, according as its functions became more complex with the spread of printed books and the increasing requirements of learning. Catalogues expanded into dictionaries, whose object was to acquaint literary men with the most important works in every branch of learning. Books were accordingly classified by their contents, and the compiler had to distinguish between degrees of relative utility, so that students might know what books to select. This duty, which devolved in most cases on men of learning, has led French writers in particular to exaggerate the province of bibliography. "La bibliographie," says Achard, "étant la plus étendue de toutes les sciences, semble devoir les renfermer toutes;" and Peignot describes it under his proposed title of *Bibliologie*, as "la plus vaste et la plus universelle de toutes les connaissances humaines." We know of no excuse for such pretensions beyond this, that books represent, in its transmissible form, the sum total of all kinds of knowledge. The bibliographer has to determine the genuineness, not the authenticity of a book; its identity of authorship or publication, not the correctness of its contents. When he pronounces judgment on its intrinsic merits he usurps the office of the critic. Some works, indeed,—like Baillet's *Jugemens des Savans, sur les Principaux Ouvrages des Auteurs*, augmentés par M. de la Monnoye, 8 vols., Amst., 1724; Blount's *Censura Celebriorum Auctorum*, London, 1690; Morhof's *Polyhistor Literarius, Philosophicus, et Practicus*, the best edition of which is that of Fabricius in 1747: the *Onomasticon Literarium* of Saxius, Utrecht, 7 vols., 1759–90; and the *Censura Literaria* of Sir Egerton Brydges, 10 vols., 1805–9,—are collections of critical bibliography of extreme value to the literary historian; but there is a wide difference in design between compilations even of this kind and works devoted to original criticism. In like manner the proper objects of classification have been neglected by many bibliographers, who have indulged in refinements of method, not as a means of facilitating reference, but for the purpose of illustrating a philosophical system of learning. Pretensions such as these, have, unfortunately, done much to discredit bibliography as a science of practical application, by investing it with a false air of mystery, and exposing it to the charge of empiricism. Its real value, in a literary aspect, depends on the recognition of its purpose as ancillary to the study of literature; not, in short, as an end, but as a means to the attainment of knowledge, by the investigation of its sources.

France must be regarded as the real mother of bibliography.[1] Italy was the field in which book-collections first began on a large scale, and that country can boast of names like Magliabecchi, Apostolo Zeno, Bandini, Audiffredi, Mazzuchelli, and Morelli, besides provincial works like Moreni's *Bibliografia della Toscana*, and Gamba's *Serie di Testi*. But the labours of French bibliographers, especially after Naudé, converted a study, more or less desultory, into a science and a systematic pursuit. In Germany, poor in public and almost destitute of private libraries, bibliography has been studied almost exclusively in its literary aspect. Belgium has shown much recent activity; but neither Holland, Spain, nor Portugal can show any modern work of importance. In England the paucity of bibliographers is the more to be regretted from the wealth of her resources. Richard de Bury, in his *Philobiblion*, had descanted on the charms of book-collecting as early as the 14th century; but Blount's *Censura*, published in 1690, was the only regular

[1] The term *bibliognoste* originated with the Abbé Rive; words similarly compounded, and involving fanciful niceties of distinction, are common among French writers on this subject (*Peignot*).

treatise on bibliography up to that date. Oldys, whose *British Librarian* first appeared in 1737 but was never completed, was among the first in this country to divert the public taste from an exclusive attention to new books, by making the merit of old ones the subject of critical discussion; and Maittaire, who was second master of Westminster School, and who died in 1747, first established the study of bibliography in England on a solid basis. The labours of Dibdin we shall have occasion frequently to refer to; they mark a new phase of bibliography in England which followed the opening up of the Continent after the great war with France. The science in America has been cultivated only recently; but the names of Cogswell, Ticknor, and Jewett are already well-known to bibliographers.

I. *The Constituent Parts of Books, and Differences of Editions.*

The history of the materials used for early manuscripts—a subject fruitful in research—lies outside the limits we have proposed for bibliography as the study of printed literature. Fortunately for the spread of books, in the modern sense of the term, the invention of printing was preceded by the important discovery of the art of making paper from linen rags. The precise date of this discovery is not known, nor are writers agreed as to the country in which it was made; but it seems to be ascertained that this kind of paper was in general use in Europe before the end of the 14th century. Caxton and the other early English printers appear to have used paper of foreign manufacture. Such questions, among others, as the relative priority of different editions, or the productions of different presses, are frequently to be determined by a comparison of the constituent elements of the books themselves; but the subject is too technical to be noticed in detail. The question as to the origin of printing belongs strictly to a consideration of that art; but as its history and its progress are illustrated by the productions of different presses, the bibliographer will find much matter of interest in the principal works devoted to the subject. Prominent among these are the *Monumenta Typographica* of Wolfius, Hamburg, 1740; Meerman's *Origines Typographicæ;* Prosper Marchand's *Histoire de l'origine et des premiers progrès de l'Imprimerie*, 1740—a valuable supplement to which was published by M. Mercier, Abbé de Saint Leger, in 1773, and republished in 1775; and Lambinet's *Recherches historiques, littéraires, et critiques sur l'origine de l'Imprimerie*, first published at Brussels in 1799.

An accurate knowledge of the different forms of books is necessary to the bibliographer, as without it no book can be correctly described; and however easy such knowledge may appear, it is yet certain that errors in this respect have been committed even by experienced bibliographers, and that doubts have been entertained as to the existence of editions, owing to their forms having been inaccurately described.[1] These mistakes generally proceed from this, that there are different sizes of paper comprehended under the same name. But the water-lines in the sheets afford a test, as they are uniformly perpendicular in the folio and octavo, and horizontal in the quarto and duodecimo sizes. In the infancy of printing the sizes were generally folio and quarto, and some have supposed that no books were printed in the smaller forms till after 1480; but M. Peignot instances many editions in the smallest forms of an earlier date; as may be seen in the article "Format" of the supplement to his *Dictionnaire de Bibliologie*. The subject of water-marks is treated at length in Sotheby's *Principia Typographica.*

The respective merits of different editions can be ascertained often only by minute inquiries. It is a principal object of the bibliographical dictionaries, to be afterwards mentioned, to point out those editions of important works which such inquiries have discovered to be the best. There are many particulars in which one edition may differ from or excel another. There may be differences or grounds of preference in size, in paper, and in printing. Later revision by the author may give his work, when it comes to be reprinted, a complexion differing largely from what it had at the first; while the first edition exhibits his original thoughts as they came fresh from his pen. One edition may derive its superiority from being furnished with notes, an index, or a table of contents. Plates make great differences in the value of editions, and even in the value of copies of the same edition. In the beautifully engraved edition of *Horace* by Pine, a small error in the first impressions serves as a test whether any copy contains the best engravings of those elegant vignettes which illustrate that edition. The medal of Augustus, on page 108 of the second volume, has in the first copies the incorrect reading *Post Est* instead of *Potest;* this was rectified in the after impressions; but as the plates had meanwhile sustained some injury, the copies which show the incorrect reading are of course esteemed the best. Dibdin, in his *Bibliomania*, points out this as an instance of preference founded on a *defect;* but the real ground of preference is the superiority of the impressions, ascertained by the presence of this trifling defect. There are sometimes differences between copies of the same edition of a work.[2] Walton's *Polyglot Bible* is a celebrated instance. The printing of that great work, for which Cromwell liberally allowed paper to be imported free of duty, was begun in 1653 and completed in 1657, and the preface to it in some copies contains a respectful acknowledgment of this piece of patronage on the part of the Protector; but in other copies the compliment is expunged, and replaced by some invectives against the republicans,—Walton having on the Restoration printed another preface to the copies which had not by that time been disposed of.[3]

II. *Early Printed Books.*

The first productions to which the name of *Books* has been applied, were printed, not with movable types, but from solid wooden blocks. These consisted of a few leaves only, on which were impressed images of saints and other historical pictures, with a text or a few explanatory lines. The ink was of a brownish hue, and glutinous quality, to prevent it from spreading. These are known by the name of *Image Books*, or *Block Books*, and are generally supposed to have succeeded the earlier impressions for playing cards, which are dated back to the end of the 14th century. Strictly speaking, they were the immediate precursors, rather than the first specimens of typography; in fact, they mark the transition to that art from engraving.[4] Peignot puts their number at seven or eight, but others have extended it to ten. They belong chiefly to the Low Countries, and were often reprinted, as is generally thought, during the first half of the 15th century, and, indeed, after

[1] See Boulard, *Traité Elémentaire de Bibliographie*, pp. 38, 39.

[2] The *Voyage to Cadiz* is sometimes wanting in Hakluyt's *Navigations*, 1598–1600. A reprint is often inserted to supply this want, which may be known from the original by its having only seven paragraphs in p. 607, vol. i., whereas the original has eight. The *original* ends on p. 619, the *reprint* on p. 620.

[3] See vol. i. of Dr Clarke's *Bibliographical Dictionary* for some curious details on this point.

[4] Mr Holt, who contends that printing preceded engraving, ascribes the date of 1423 on the *St. Christopher* to a forgery for 1493, and asserts that no copy of the *Biblia Pauperum* was known before 1485. See *Notes and Queries*, 4th series, ii. 265.

the discovery of printing, properly so called. One of the most celebrated is the *Biblia Pauperum*,[1] consisting of forty leaves, printed on one side, so as to make twenty when pasted together, on which passages from Scripture are represented by means of figures, with inscriptions. It appears to have been originally intended for the use of those poor persons who could not afford to buy complete copies of the Bible. Some fugitive sheets still attest the primitive attempts at printing, in the modern sense of the word. *The Letters of Indulgence* of Pope Nicholas V., two editions of which, on a small sheet of parchment, were printed in 1454, fix the earliest period of the impression of metal types, with a date subjoined.[2] The earliest known book, however, of any magnitude, and probably the first thus printed, was the undated *editio princeps* of the Bible, commonly known as the Mazarin Bible, from a copy having been found by De Bure in the library of the Cardinal. It is undated, but authorities generally concur in ascribing it to a period between 1450 and 1455. The work is usually divided into two volumes, the first containing 324, and the second 317 pages, each page consisting of two columns. The characters, which are Gothic, are large and handsome, and resemble manuscript. No fewer than twenty copies are known to be extant.[3] The first printed book with a date is the *Psalter* of Fust and Schöffer, printed at Mentz in 1457, as a somewhat pompous colophon announces. It was found, in 1665, in the Castle of Ambras, near Innsbruck, where the Archduke Francis Sigismund had collected a quantity of MSS. and printed books, taken chiefly from the library of Corvinus. A few other copies are in existence, one of which was bought under Louis XVIII. for the Royal Library at Paris for the sum of 12,000 francs. Whether the types employed were wooden or metallic has been disputed between Van Praet and Didot. As a specimen of early printing the work is magnificent; it contains richly embellished capitals in blue, red, and purple.

Besides these monuments of infant typography, a special interest attaches to the productions of the 15th century. They are usually known as *Incunabula*, a term applied to them by modern German writers. Brunet, following Santander, estimates their number at 18,000 or 20,000; but it is probable that many duplicates are included in this reckoning. They came into demand chiefly at the beginning of the last century, and especially about 1740, at the third centenary of printing. The passion for them at first was indiscriminate, but preference afterwards was given to the presses of Mayence, Bamberg, Cologne, Strasburg, Rome, and Venice.

As regards these early printed books, a knowledge of typography is necessary to the bibliographer, to enable him to verify their identity. A brief reference to some of their leading peculiarities must suffice here. The printer's name, and the date[4] and place of printing were at first omitted, the printer imitating the reticence of the copyist, and the book being a mere fac-simile of the manuscript. In Germany and the Low Countries few dated books are found before 1476 or 1480. Title-pages appear to have come in a few years later; none of Caxton's works, with one doubtful exception, have any. Titles to chapters were first used in the *Epistles of Cicero*, 1470. According to Palmer, the use of signatures, or letters at the bottom of the page to guide the bookbinder in the arrangement of the sheets, began with Zarot in a Terence printed by him at Milan in 1470. Marolles ascribes them to John of Cologne, who printed at Venice in 1474, and the Abbé Rive to John Koelhof, a printer of Cologne. They were in use in that city in 1475, and at Paris the next year, but were not employed by Caxton until 1480. Catch-words, which, like signatures, preceded the numbering of pages, are found in MSS. of the 11th century, and were first applied to printing by Vindelin de Spira at Venice. Their purpose, to direct the binder, had been previously supplied by *Registers*, or alphabetical tables of the first word of chapters, which were introduced about 1469. The earliest system of numbering was applied, not to pages, but to leaves, a large Roman figure being placed at the top of the *recto* in each leaf. The characters were uniformly Gothic--the foundation of our Black-letter—until 1467, when Gothic was supplanted by the Roman type, introduced in that year at Rome, and improved on by Jenson at Venice. It was first used in England by Pynson. *Italics* were first used by Aldus in his *Virgil* of 1501; they are said to have been suggested to him by Petrarch's writing, and were employed to compress matter into his small octavos without the inconvenience of abbreviations. Hebrew characters began at Soncino, in the duchy of Milan, in 1482, and at Naples in 1487. The only points first used were the colon and full stop; but Aldus improved punctuation by giving a better shape to the comma and adding the semicolon. With Caxton oblique strokes took the place of commas and periods. The form of the earliest books was chiefly folio and quarto. Almost every page abounded in abbreviations or contractions. Blank spaces were left for capitals and the first letters of periods, which were afterwards filled up by the illuminator. The Basel press was noted for its ornamental initials; and Calliergus at Rome and the Paris printers excelled in decorative printing of this kind. The taste for embellishment led to ornamental title-pages about 1490, the usual ornament at first being the "author at his desk." The custom of coloured frontispieces appears to have prevailed until the end of last century. Decorated borders appear in the first page of some of Sweynheim and Pannartz's productions; few ornaments, however, were introduced into the body of the text before the first Hebrew publications.[5] The *Aulus Gellius* of 1469 by the same printers is cited as the first book with a preface; and their *Apuleius* of the same year contains the earliest marginal notes. For further information on the characteristics of early printed books the reader will do well to consult Palmer's *General History of Printing* (a work ascribed chiefly to George Psalmanazar); Jungendres, *De Notis Characteristicis Librorum a Typographiæ Incunabulis ad annum* 1500 *impressorum*; and Marolle's *Recherches sur l'Origine des Signatures et des Chiffres de Page.*

[1] So called first by Heinecken, *Idée générale d'une collection complete d'Estampes*, 8vo, 1771. Dibdin, in his *Bibl. Spenceriana*, and Ottley, in his *History of Engraving*, have given fac-similes of the figures in several of the block-books. See also Falkenstein's *Geschichte der Buchdruckerkunst in ihrer Entstehung und Ausbildung*, 4to, 1840; Schelhorn's *Amœn. Lit.*; the works of Maittaire, D. Clement, Fournier, Meermann, Papillon, and De Bure; and J. P. Berjeau's *Catalogue illustré des livres xylographiques*, 1865. Heinecken was the chief authority until recently, when his views, especially on the chronology of the block-books, have been much contested. Sotheby's *Principia Typographica*, 3 vols., 1858, is the most important work on this subject in late years. The author has also attempted to elucidate the character of the water-marks of the period.

[2] Dibdin's *Bibl. Spencer.*, i. xliv.

[3] Before the discovery of the Mazarin Bible, the Bamberg Bible of Pfister generally passed for the first printed book. Schelhorn has written a treatise maintaining its priority of age. As to the Mazarin Bible, see an article by Dibdin in Valpy's *Classical Journal*, No. 8. The kind of types employed upon it has been the subject of much dispute.

[4] The date was sometimes computed by Olympiads, as in the *Ausonii Epigrammata*, printed at Venice in 1472. Middleton, who has written to prove that the Oxford *Expositio S. Jeronimi* of 1468 contains a falsified date, quotes, as an example, the *Decor Puellarum* of Jenson, at Venice, which is dated 1461, instead of 1471, in order, he says, to give priority to the printer over John de Spira, whose first work appeared in 1469 (*Works*, iii. 236).

[5] For this class of books see De Rossi's *Annales Hebræo-Typographici*, 1795–99.

The devices of the early printers are of importance to the bibliographer, since questions occur as to the early editions which can only be ascertained by discovering the printer's name. The invention of marks or vignettes is ascribed by Laire (*Index Librorum Sæc.* XV., ii. 146) to Aldus; he traces them to a Greek Psalter of 1495. A device, however, consisting of two shields occurs in Fust and Schoffer's Bible of 1462. They were not used by Ulric Zell, the first printer at Cologne, nor by the fathers of the Paris or Venetian presses. Monograms or ciphers were frequently employed, with initial letters of names or other devices curiously interwoven, and these furnish a trustworthy clue to identity. The monograms of the Early English printers are explained in Ames's *Typographical Antiquities*. Of the devices of different presses the best fac-similes are given in Dibdin's *Bibliographical Decameron*, vol. ii. Orlandi's *Origine e Progressi della Stampa*, Bologna, 4to, 1722, is a work of indifferent merit. The *Thesaurus Symbolorum ac Emblematum* of Scholtz, published at Nuremberg in 1730, and Spoerlius's *Introductio in Notitiam insignium Typographorum*, of the same year, are the best and most interesting authorities on this subject.

The *incunabula* of the various early presses have been treated separately by different writers. Schwarz in 1740 and Wurdtwein in 1787 reviewed the productions of the Mentz press. Those of Nuremberg were noticed by Röder in 1742; and a catalogue of them, in the library of that town, was compiled by Saubert in 1643. In Italy, the Roman press is represented by Michael Canensio in 1740, and more particularly by Audiffredi in 1783, who afterwards extended his researches to all early Italian productions. The books issued from Milan between 1465 and 1500 have been noticed by Saxius; the Parmese editions by Affo in 1791; those of the Spiras at Venice by Pellegrini in 1794; those of Friuli by Bartolini in 1798; and those of Ferrara by Antonelli in 1830. The early Paris press has been copiously treated by Chevillier, and that of Lyons by Péricaud, 1840. For Spain there is Caballero in 1793; and the works printed in the Low Countries are reviewed at length in Meermann's *Uitvindung den Bockdrukkonst*, Amsterdam, 1767. Herbert, Ames, and Dibdin well-nigh exhaust the subject of early English bibliography. The different collections of *incunabula* in public or private libraries have been noticed in more or less detail. Seemiller in 1785 catalogued upwards of 1800 editions of the 15th century at Ingolstadt. Those in the Magliabecchian library at Florence have been described by Fossi (or rather Follini) in 1793–95. The collection of Lomenie de Brienne is known through the labours of the elder De Bure and his continuator, Laire; and the treasures of Count Boutourlin were catalogued by Audin de Rians. Lambeth library contains many specimens, which have been noticed by Maitland; and the splendid collection of Earl Spencer at Althorp has met with a worthy exponent in Dibdin.[1]

For more general information on this subject the reader may consult the following works:—*Index Librorum ab inventa Typographia ad annum* 1500, *cum notis*, 2 vols. 1791. This work, by Laire, is one of the most useful of its kind, and it has the advantage of four indexes, which furnish a ready reference to its contents. De Bure, in the seventh volume of his *Bibliographie Instructive*, has given a list of 15th century books, classed in the order of the different towns. M. La Serna Santander's *Dictionnaire Bibliographique choisi du quinzième siècle*, 3 vols., 1805, is a very learned and exact work, and, like Laire's *Index* above mentioned, embraces only the rarest and most interesting publications of the 15th century. See also the *Lettres de l'Abbé de St. L.* (Mercier de St. Leger), *au Baron de H.* (Heiss), Paris, 1785. Maittaire's *Annales Typographici ab artis inventæ origine* is a mine of learning and research. The first volume, published in 1719, embraces the period from the origin of printing to 1500, but his researches into printed literature extended in the third volume to 1557; and there is an appendix which affords a partial continuation to 1664. A supplement to this elaborate work, by Denis, in 2 vols. 4to, appeared at Vienna in 1789, and contains 6311 articles omitted by Maittaire. Panzer's *Annales Typographici* was founded on the preceding work, and consisted of eleven volumes, which were published at Nuremberg between 1793 and 1803. It was intended to be limited to the 15th century, but, after the appearance of the fifth volume, the period was extended to the year 1536. German publications were reserved for a separate work, which bears the title of *Annalen der älteren deutschen Literatur*. The *Repertorium Bibliographicum* of Lud. Hain, 4 vols. 1826–38, contains an alphabetical list of no less than 16,299 books printed during the 15th century, which are described with rare minuteness and accuracy. The author's labours were terminated by death, when he had advanced as far as UG. The addition of bibliographical notices, pointing out first editions and books of remarkable rarity and price, would have much enhanced its interest and value. The *Literatur d. ersten 100 Jahre nach d. Erfindung d. Typographie*, by Chr. F. Harless, was published at Leipsic in 1840. Its object differs from that of the preceding works, in making the notice of early editions subordinate to his purpose of illustrating thereby the transition and progress of contemporary learning.

III. *Rare and Curious Books.*

This branch of what Ebert terms "restricted" bibliography belongs peculiarly to the book-collector and bookseller, if regard be had especially to the inclinations of purchasers, the actual demand, and the marketable value of books. Rarity and price depend very much on each other; rarity makes them dear, and dearness makes them rare. Hallam asserts that the price of books was reduced four-fifths by the inventing of printing. From a letter of Andreas, bishop of Aleria, to the pope, in his preface to the *Epistles of Jerome*, it would seem that 100 golden crowns was the maximum demanded for a valuable MS., and that the first printed books were sold for about 4 golden crowns a volume. At any rate, one natural effect of printing was to restrict the number of rare books to a separate class. Cailleau, who has been followed by most other writers on this subject, distinguishes between *absolute* and *relative* rarity. The former term is applied to those books or editions of which only a small number has been printed. Such for the most part are works printed for private circulation, as those of the Strawberry Hill Press, which are very scarce and enormously dear. This class of English books is treated in the *Bibliographical Catalogue of Books, privately printed*, by John Martin, 1834, republished, with additions, in 1854, 8vo. Much of the value attached to editions of the 15th century arises from the limited number of impressions. They were seldom more than 300; John of Spira printed only 100 copies of his *Pliny* and *Cicero;* and printers had the example of Sweynheim and Pannartz, who were reduced to poverty by their surplus copies, to avoid exceeding the current demand. Suppressed works belong to the same category, in proportion to the success of prohibition. Others owe their scarcity to accidental destruction; as, for instance, the second volume of Hevelius's *Machina Cœlestis*, 1679, which would have shared the fate of the remainder of his works, on the burning of his house, had the author not previously given some copies to his friends. At the great fire of London in 1666 there were some works of Dugdale, among others writers, as well as the first volume of Prynne's *Records of the Tower*, of which only a few copies escaped; but their value has been reduced by subsequent impressions. The same kind of rarity attaches to *Editions de luxe*, chiefly made for rich amateurs; to large paper copies and *tall* copies, *i.e.*, copies of a work published on paper of ordinary size and barely cut down by the binder; and to books printed on coloured paper. A list of the last-named is given by Duclos and Cailleau, and reprinted by Horne in his

[1] *Bibliotheca Spenceriana.* To this were afterwards added his *Ædes Althorpianæ*, with a supplement, 1822, and the volume on the *Cassano Library*, with a general index, 1823. The beauty of the fac-similes alone would entitle these works to the front rank of books on bibliography.

Introduction to Bibliography. It includes an edition of Sterne's *Sentimental Journey*, three copies only of which were printed at Paris in 1802, on rose-coloured paper, and the complete *Works of Voltaire*, edited by Beaumarchais (Kehl, 1785), twenty-five copies of which were struck off on blue paper, after some had been requested by Frederick the Great for his own use, on account of the weakness of his eyesight. Vellum copies, again, have been much prized by collectors. They belong to the early days of printing, especially to the Aldine, Verard, and Giunti presses, and to those of the first English printers. Few were made between the latter half of the 16th and the beginning of the last century; but the art was revived in France by Didot and Bodoni, and the folio *Horace* of 1799 by the former is a *chef d'œuvre* of its kind. The Royal Library at Paris has a sumptuous collection of vellum copies, which have been elaborately described by Van Praet.[1] At the sale of the M'Carthy library, the *Psalter* of Fust and Schöffer on vellum was bought by Louis XVIII. for 12,000 francs. The libraries of Earl Spencer and the duke of Devonshire contain the finest specimens in this country. The *relative* rarity of books is due to a variety of causes, chiefly connected with the peculiar nature of their contents. Among works of this kind, generally speaking, are local histories, lives of learned men, books of antiquities, or of curious arts, those written in languages little known, macaronic treatises, and catalogues of private libraries. Works like the *Acta Sanctorum*, in 53 volumes, however accessible in public though not in private libraries, are rare in this sense of the term. The class of publications known as *Ana*, containing the sayings and doings of men great in their day, has become comparatively scarce. The first of these was the *Scaligerana* of 1666. The public fastened upon them at first with avidity, but the number of such productions created in time a distaste for them (see ANA, vol. i., pp. 784–5). Burton's *Anatomy of Melancholy*, which fascinated Dr Johnson, is an instance of undeserved neglect. For a long time it fell into disuse, and from being a waste-paper book, became extremely rare, until reprinted in recent times. Fugitive pieces, like political broadsides, share the penalties of an ephemeral interest. The *King's Pamphlets*, so called from having been presented by George III. to the British Museum, are the largest collection of this kind in England. It owes its origin to the industry of the bookseller Thomason.[2]

In a literary sense, a book, to deserve the title of rare, should be a work of some merit, and not one whose obscurity is due to its worthlessness. Curious books, however, depend very much on the pleasure of the curious; and the follies and caprice of collectors are summed up in the word *Bibliomania*. Some copies of Tuberville's *Book of Hunting*, 1611, were bound in deer-skin; Mr Jeffery, the bookseller, enclosed Mr Fox's historical work in fox's-skin; and a story is told of Dr Askew having caused a book to be bound in human skin, for the payment of which he was prosecuted by the binder. German bibliographers reproach us with an undue passion for book curiosities. *Bibliomania* forms the title of an amusing work by Dr Dibdin, who, though accused of a leaning to this weakness, knew well how to value the intelligent study of books. The practice was satirized as early as the time of Brandt, (see his *Ship of Fools*.) It prevailed in England chiefly during last century, and reached its height at the sale of the duke of Roxburghe's library in 1812.[3] The time, however, has passed away when the passion for collecting rare and curious books, without regard to their usefulness, merit, or beauty, was too often a failing with well-educated persons. The love of uncut and large-paper copies of vellum and first editions, and of illustrated books, has been better regulated since book-madness was attacked by the Abbé Rive, Dibdin, Dr Ferrier, and the Rev. James Beresford; and modern book-clubs like the Roxburghe (1812), the Bannatyne (1823), the Maitland (1823), and the Surtees (1834) Societies, the Abbotsford Club (1834), and the Early English Text Society, have done important service to bibliography by reprinting scarce old books.

Detached notices of rare and curious books are to be found in the catalogues of private libraries, especially those compiled by French writers during the last century. Beloe's *Anecdotes of Literature* contains much interesting matter on scarce books and their prices. The following, however, are the chief works on this subject:—Hallervord's *Bibliotheca curiosa*, Frankfort, 1687; Beyer's *Memoriæ historico-criticæ librorum rariorum*, Dresden and Leipsic, 1734; Vogt's *Catalogus historico-criticus librorum rariorum*, the best edition of which appeared at Frankfort in 1793. The author applies the epithet *rare* with more judgment than his predecessors. A supplement to his work was the *Florilegium historico-criticum librorum rariorum* of Gerdesius, first published in 1740, and again in 1763. The *Bibliothèque curieuse, ou Catalogue raisonné des livres rares et difficiles à trouver*, by D. Clement, Gottingen, 1750–60, is compiled on a more extensive plan than any of the preceding. Although consisting of 9 volumes 4to, it only extends to the letter H, terminating there in consequence of the author's death. Clement is generally blamed for a very profuse and inaccurate application of his own nomenclature; his notes, moreover, are crammed with citations, and tediously minute, but they abound with curious morsels of literary history, and it is to be regretted that the work was not completed. S. Engel, *Bibliotheca Selectissima*, Bern, 8vo, 1743; T. Sinceri, *Notitia historico-critica librorum rariorum*, Frankfort, 1753; *Bibliographie Instructive, ou Traité de la connaissance des livres rares et singuliers*, by W. F. De Bure, Paris, 1763–68, 7 vols. This work did much to popularize bibliography in France. The author criticizes parts of Clement's dictionary, but recognizes the general merit of that work. De Bure published a supplement in 1769, containing a catalogue of rare and curious books in the library of Gaignat. *Dictionnaire typographique, historique, et critique, des livres rares, estimés, et recherchés en tous genres*, par J. B. L. Osmont, 2 vols. 8vo, Paris, 1768. This work contains a fuller account of Italian books than the preceding. *Dictionnaire bibliographique, historique, et critique, des livres rares, précieux, singuliers, etc.*, by André Charles Cailleau, 3 vols. 8vo, Paris, 1790. This work was compiled, according to M. Barbier and others, by the Abbé Duclos, and was republished in 1800, with a supplementary volume, by M. Brunet. Notes are affixed to unpriced books, stating their value. *Bibliotheca Librorum rariorum Universalis*, by Jo. Jac. Bauer, 7 vols. 8vo, 1770-91. Peignot in his *Répertoire des Bibliographies speciales, curieuses, et instructives*, 8vo, Paris, 1810, has written on the elements of rarity, and the different classes of rare books.

IV. *The Classics.*

Fortunately for the preservation of ancient literature, the discovery of printing coincided very closely with the full development of that zeal for classical learning, which had begun with the 15th century.[4] To Italy belongs the chief glory of first embodying, in an imperishable form, those materials which the industry of Poggio and others had rescued from the dust of monastic libraries. In rapid succession the first editions of the classics issued from Italian presses; no less than fifty of these are enumerated by Panzer. *Apuleius*, *Aulus Gellius*, *Cæsar*, *Livy*, *Lucan*, *Virgil*, and portions of *Cicero*, were printed by Sweynheim and Pannartz at Rome before 1470; while the rival press of the Spiras at Venice boasted of *Plautus*, *Tacitus*,

[1] *Catalogue des livres imprimés sur Velin de la Bibliothèque du Roi*, 1822–28, 6 vols. See his supplemental catalogue of similar books in other libraries, 1824, 4 vols. royal 8vo. Panzer, as he informs us in his *Essai sur l'Histoire du Parchemin et du Velin*, 1812, intended, but did not execute, a comprehensive work on vellum curiosities. See also Schelhorn's *Amœn. Litter.*, vol. i.

[2] See Oldys's *Dissertation on Pamphlets*, and the *Icon Libellorum* of Myles Davis, a *résumé* of which is given in Disraeli's *Amenities of Literature*. Aungervyle de Bury admitted *Panfleti exigui* into his library.

[3] At this sale the Valdarfer Boccaccio of 1471 fell to the Marquis of Blandford, after a spirited competition with Earl Spencer, for £2260.

[4] Hallam's *Lit. of Europe*, i. 146; Roscoe's *Lorenzo de Medici*.

Priscian, *Sallust*, *Catullus*, *Tibullus*, and *Propertius*. From Brescia came *Lucretius*, from Vicenza, *Claudian*; Ferrara and Naples gave birth to *Martial* and *Seneca*. In Germany, France, and the Low Countries, on the other hand, the progress at first was slow. Few classics were printed out of Italy before 1480, or, indeed, until the last ten years of that century. The *De Officiis* of Cicero, it is true, had appeared at Mentz in 1465,—the first portion of any classical work committed to the press, unless precedence is given to the *De Oratore* of Sweynheim and Pannartz at Subiaco. But with that exception the first impressions of *Terence* and *Valerius Maximus* at Strasburg, and of *Sallust*, and, perhaps, *Florus* at Paris, are all that Cisalpine presses contributed of that kind within the period under review. The first appearance of *Velleius Paterculus* at Basel and of *Anacreon* and *Menander* at Paris was not until the next century was well advanced. In Spain the first classical book was a *Sallust* of 1475. In England, the earliest was a *Terence*, printed by Pynson in 1497; but, besides that, *Virgil*, *Sallust*, and Cicero's *Offices*, together with two Greek books, were the only classics published down to 1540. A complete edition of *Cicero*, printed in 1585 at London, was the chief Latin work up to that date. A neat edition of Homer's *Iliad* appeared in 1591, and the first impression of *Herodotus* in this country came out in the same year at Cambridge. Our early printers were content with French translations for their versions and abridgments; and Gawin Douglas, in the preface to his translation of *Virgil*, records his indignation at the injustice done to the "divine poet" by the second hand translation of Caxton.

Most of the Latin classics had appeared in print before the art was employed on any Greek author. This was due rather to the want of adequate editorship than to any indifference to Greek in Italy; for the taste for that language had steadily increased since the arrival of the learned Greeks from Constantinople, and the want of printed editions became general before the close of the 15th century. To Aldus belongs the glory of ministering to that desire, by publishing, in quick succession and with singular beauty and correctness, almost all the principal authors in that tongue. Beginning in 1494 with Musæus's *Hero and Leander*, he printed before 1516, the year of his death, upwards of sixty considerable works in Greek literature. The list includes the first impressions of *Aristophanes*, *Herodotus*, *Theocritus*, *Sophocles*, *Thucydides*, *Euripides*, *Demosthenes*, *Pindar*, and *Plato*. The *editio princeps* of Aristotle is the finest of his productions. Himself, in several cases, editor as well as printer, he had the assistance of the most learned scholars of the day; and the handy size of his octavos, which he substituted for the more cumbrous quartos after his removal from Venice, added to the popularity of his editions. Within two years after Aldus commenced his labours, Greek printing began at Florence with the works of Callimachus,[1] Apollonius Rhodius, and Lucian; at Rome, however, the earliest work was the *Pindar* of Calliergus in 1515.[2] At Paris the first Greek press of importance was established in 1507 by Gourmont, but the days of its chief celebrity date from his successors Colines and Stephens. Aldus, though the most prolific, was not the earliest Greek printer. The first entire work in that language was the *Grammar* of Constantine Lascaris, printed by Zarot at Milan in 1476. Homer's *Batrachomyomachia* was the earliest printed Greek classic; his complete works first appeared in the Florence *Homer* of 1488, a volume which, Gibbon observes, "displays all the luxury of the typographical art." Besides these works, the *Orations* of Isocrates had appeared in 1493. Aldus has been unduly eulogized by his biographer, M. Renouard,[3] who has represented him as having given an entirely new direction to the art of printing, and indeed to the literary taste of Europe. His taste for Greek he had imbibed from the age: he saw that there was a great and growing want of Greek books, and his peculiar praise lies in this, that he applied himself to supply it with much more constancy and skill and with much more learning than any other printer of that period. His preface to Aristotle's *Organon*, published in 1595, amply recognizes the demand for Greek books. "Those," he says, "who cultivate letters must be supplied with books necessary for that purpose; and till this supply is obtained I shall not be at rest."[4]

The *absolute* rarity of the first editions of the classics it is difficult to determine with precision. They have been much prized by collectors, especially during last century, though their price has fluctuated considerably at different times. The date of some, as for instance, of *Juvenal*, *Q. Curtius*, and *Horace*, is conjectural; and the last-named is one of four classics,—*Lucan*, *Plutarch*, and *Florus* being the other three,—of which the printer is unknown. The Naples edition of *Horace* of 1474 is called by Dibdin[5] the "rarest classical volume in the world," and it was chiefly to possess this book that Earl Spencer bought the famous library of the duke of Cassano. Of the first edition of *Lucretius* only two copies are believed to exist; and not one in its integrity of Azzoguidi's *editio princeps* of Ovid. On the other hand, there are several classical authors, of whom the second and even later impressions are far the most valuable and scarce. The intrinsic merit of the *editiones principes* of the classics is too unequal to admit of any general description. Their chief value, in a literary sense, consists in the security afforded by printing against the further progress of transcriptional error; but it would be a great mistake to imagine that the text was then finally established. Maittaire gives precedence to their authority as equivalent to that of the MSS. from which they were taken, but the question obviously turns on the character of those MSS. themselves. Later discoveries and the progress of critical research confirm the testimony of many of the first editors, in their prefaces,[6] regarding the insufficiency and mutilated character of their materials. Thus Grævius observes of the celebrated *editio princeps* of Cicero's *De Officiis* by Fust, that it was printed from a very inaccurate manuscript. Schelhorn, in his *Amœnitates Literariæ*, insists, with good reason, on the want of collation among the first editors. Frequently the first manuscript that offered itself was hastily committed to the press, in order to take advantage of the recent discovery; and fragments of different manuscripts were patched together to form *Opera Omnia* editions, without regard to the relative authority of their contents. On the other hand there are first editions which represent a single lost archetype, and whose value, therefore, cannot be exaggerated, while others

[1] This *editio princeps* is among the scarcest of Greek capital letter productions.

[2] Roscoe's *Leo X.*, ii. 257-8. Greek types, according to Panzer, had first been used in a treatise of Jerome, printed at Rome in 1468; and detached passages are found in some of the first copies of Latin authors.

[3] *Annales de l'Imprimerie des Aldes*, Paris, 1825, and third edition in 1834. Renouard afterwards published a similar work on the family of the learned printers, Robert and Henry Stephens, *Annales de l'Imprimerie des Estiennes*, Paris, 1837, 2 vols. 8vo.

[4] The preface is translated in Roscoe's *Leo X.*, i. 110.

[5] The bibliography of first editions of the classics is treated copiously by this writer in his *Introduction to the Classics*, his *Bibl. Spenceriana*, and his *Catalogue of the Cassano Collection*. The prices of many valuable first editions at a sale in London in 1821 are given at the end of the last-mentioned work. See also a curious chapter on "First Editions" in Marchand's *Histoire de l'Imprimerie*.

[6] These prefaces have been edited by Botfield, with an introduction of some merit.

represent copies of undoubted merit. La Grange assures us, in the preface to his French translation of *Seneca*, that he never, in any case of difficulty, consulted the first edition of 1475, without finding a solution of his doubts. The fact is that each *editio princeps* must be judged by itself. It is to such scholars as Turnebus, Muretus, and Lipsius that we owe a juster estimate of their relative value, than prevailed in the early days of printing. Victorius has been called the "Sospitator Ciceronis;" and the real restorers of Greek learning are to be found in Scaliger, Casaubon, Budæus, Camerarius, and Stephens. The text of the classics has been slowly and laboriously constructed, and in some cases, as with Aristophanes, Dion Cassius, and Pliny, among others, a manuscript, discovered in modern times, has superseded entirely the authority of early editions. This branch of the subject is fully treated in an article in the *Edinburgh Review* on "Classical Manuscripts and First Editors" (Jan. 1873).

Sets of the classics, more or less complete, have been published at different times, and for different purposes. Among the earliest and most important are the *Delphin* editions, prepared, by order of Louis XIV., at the instance of the duke de Montausier, for the use of the Dauphin. The duke had been in the habit of studying the classics on his campaigns, and the want of books of reference appears to have suggested to him the idea of a uniform series of the principal classics, with explanatory notes and illustrative comments. On his becoming governor to the Dauphin, the scheme was carried into execution; and Huet, bishop of Avranches, a preceptor of the prince, was entrusted with the choice of authors and editors, and with the general supervision of the series. A list of the editors is given by Baillet in his *Critiques Grammairiens*. The collection, which, including Danet's *Dictionary of Antiquities*, extends to sixty-four volumes quarto, is of very unequal merit; but the copious verbal indices, which were added by the direction of Huet, afford a useful means of reference to particular passages. Only Latin classics, however, are included in the series; and "it is remarkable," as Dr Aikin observes, "that *Lucan* is not among the number. He was too much the poet of liberty to suit the age of Louis XIV." The entire collection, enlarged with the notes of the *Variorum* editions, was republished in 1819–1830, by A. J. Valpy, forming in all 185 vols., 8vo. These *Variorum* classics number upwards of 400 volumes, and were edited in the course of the 17th and 18th centuries. A complete collection is very rare; Peignot mentions one belonging to M. Mel de Saint-Ceran, which was sold for 3000 livres. For the names of the authors and commentators see De Bure's *Bibliographie*, vol. vii. p. 680, and Osmont's *Dictionnaire*, vol. ii. p. 411. The editions most prized by collectors are the Elzevirs and the Foulises. The *Elzevirs*, or properly Elseviers, were a family of famous printers and booksellers at Amsterdam, no fewer than fifteen of whom carried on the business in succession from 1580 to 1712. Their *Pliny* (1635), *Virgil* (1636), and *Cicero* (1642), are the masterpieces of their press; the last of the family brought out editions in 12mo and 16mo.[1] A full list of their publications is given in Brunet's *Manuel*, vol. v., *ad fin.* The *Annales de l'Imprimerie Elsevirienne*, by Pieter, 1851 and 1858, supersedes the authority of previous works on that subject, and contains much curious research. The project of reprinting the Elzevir editions, which originated in 1743 with the Abbé Lenglet-Dufresnoy, led to the famous *Barbou* collection, commenced by Coustelier and continued by Joseph Gaspard Barbou, one of the family of Paris printers and booksellers of that name, and extending finally to 76 volumes in 12mo. Lemaire's *Bibliotheca Classica Latina*, 1819–26, which was dedicated to Louis XVIII., is one of the best collections of Latin classics which exists in France, although the list of authors is incomplete, and the notes far too voluminous. The whole series extends to 151 volumes in 8vo. The editions of Robert and Andrew Foulis, printers at Glasgow, were the finest which Britain produced during the 18th century. Their *chef d'œuvre* was the *Horace* of 1744, each printed sheet of which, probably after the example of Robert Stephens at Paris, was hung up in the college of Glasgow, and a reward offered for the discovery of any error.

[1] Without disparaging the Elzevirs, it must be remembered that their texts were mere re-impressions, and did not rest, like those of Aldus and the Stephens, on ancient MSS.

Among the most useful bibliographical accounts of the classics may be mentioned the following:—*A View of the Various Editions of the Greek and Roman Classics, with Remarks*, by Dr Harwood,—this work, first published in 1775, is still a convenient manual of reference; *Degli Autori Classici, sacri e profani, Græci et Latini, Biblioteca portatile*, 2 vols., Venice, 1793, a compilation of the Abbé Boni and Bartholomew Gamba, and containing a translation of the preceding; Dibdin's *Introduction to the Knowledge of Rare and Valuable Editions of the Classics*, first published in 1802, and greatly enlarged in subsequent editions, containing a full account of Polyglot Bibles, of the Greek and Latin editions of the Septuagint and New Testament, and of lexicons and grammars; *A Manual of Classical Bibliography*, by J. W. Moss, 2 vols., 1825, noticing at length the different translations of the classics, the prices obtained for the rarer editions at public sales being also specified; *A View of the English Editions and Translations of Greek and Latin Authors*, by Brugemann, London, 1797; Engelmann's *Bibliotheca Scriptorum Classicorum*, Leipsic, 1847–53, containing an account of German editions between 1700 and 1852, while Greek and Latin classics printed in Germany and France are noticed in the *Répertoire de la littérature ancienne*, by F. Scholl, Paris, 1808; *Handbuch der Classischen Literatur*, by G. D. Fuhrmann, Halle, 1807–10, 5 vols. 8vo.; Hebenstreit's *Dictionarium*, Vienna, 1828; and the *Handbuch der Classischen Bibliographie*, Leipsic, 1830–34,—all of them works of considerable merit. The improved editions, by Harless and Ernesti, of the *Bibliotheca Græca* and *Bibliotheca Latina* of Fabricius are well known as immense magazines of classical lore, but they extend over a much wider field of inquiry than is embraced by bibliography.

V. *Anonymous and Pseudonymous Books.*

Books of this class originate, generally speaking, either from the necessities or the caprice of authorship.[2] Their number, however, has been such as to occupy, at an early time, the attention of bibliographers. In 1669 Frederick Geisler, professor of public law at Leipsic, published a dissertation, *De Nominum Mutatione*, which he reprinted in 1671, with a short catalogue of anonymous and pseudonymous authors. About the same time, a similar but more extensive work had been undertaken by Vincent Placcius, professor of morals and eloquence at Hamburg, which was published in 1674 with the title *De Scriptis et Scriptoribus anonymis atque pseudonymis Syntagma*, in which the writer invited information from learned men in Europe. Four years later, John Decker, a German lawyer, published his *Conjecturæ de Scriptis adespotis pseudepigraphis, et supposititiis*, which was republished in 1686, with the addition of two letters on the same subject, one by Paul Vindingius, a professor at Copenhagen, and the other by the celebrated Peter Bayle. In 1689 appeared the *Centuria plagiariorum et pseudonymorum* of John Albert Fabricius, as well as a letter to Placcius from John Mayer, a clergyman of Hamburg, under the title—*Dissertatio Epistolica ad Placcium, qua anonymorum et pseudonymorum farrago exhibitur.* The complete fruits of Placcius's researches were published after his death in a folio volume at Hamburg in 1708, by Matthew Dreyer, a lawyer of that city. The work was now entitled *Theatrum Anonymorum et Pseudonymorum;* and, besides an Introduction by Dreyer and a Life of Placcius by Fabricius, it contains, in an

[2] Baillet, in his *Jugemens des Savans*, i. 1690, notices several motives for concealed authorship.

Appendix, the before-noticed treatises of Geisler and Decker with the relative letters of Vindingius and Bayle, and the Dissertation of Mayer. This elaborate work contains notices of six thousand books or authors; but it is ill-arranged and frequently inaccurate, besides being cumbered with citations and extracts, equally useless and fatiguing.

The subject of false and fanciful names attached to books had been undertaken in France by Adrien Baillet, nearly about the same period that Placcius commenced his inquiries. In 1690 this author published his *Auteurs Déguisés*; but this is little more than an introduction to an intended catalogue which Baillet never completed, being deterred, as Niceron says, by the fear lest the exposure of concealed authors should in some way or other involve him in trouble. In this piece, which was reprinted in the sixth volume of De La Monnoye's edition of Baillet's *Jugemens des Savans*, there are some curious literary anecdotes, especially with reference to the passion which prevailed after the revival of letters for assuming classical names. In Italy these names were so generally introduced into families, that the names of the saints, hitherto the common appellatives, almost disappeared from that country. A similar rage for assuming the names of celebrated authors was common among French writers in the 18th century.

The taste for this kind of research, which the work of Placcius had diffused in Germany, produced several supplements to it in that country. In the *De Libris anonymis et pseudonymis Schediasma*, published by Christopher Augustus Neumann in 1711, there is a dissertation on the question, Whether it is lawful for an author either to withhold or disguise his name? which question he decides in the affirmative. But the most considerable of these supplements was that published in 1740 by John Christopher Mylius, librarian at Hamburg. It contains a reprint of the *Schediasma* of Neumann, with remarks, and a list of 3200 authors, in addition to those noticed by Placcius. The notices of Mylius, however, are limited to books in Latin, French, and German. The younger De Bure occupied himself partially with these researches: his omissions were supplied by M. Née de la Rochelle in his *Table destinée à la Recherche des Livres anonymes qui ont été annoncés dans la Bibliographie Instructive*, Paris, 1782. The names of several anonymous writers were discovered by Rollin in his *Traité des Études*, by Jordan in his *Histoire d'un voyage littéraire fait en* 1783; and by Bayle in his *Réponse aux Questions d'un provincial*. In 1758 the Abbé de la Porte published his *France littéraire*,[1] which was republished with large additions in 1769 by the Abbé de Hebrail. Both editions contain numerous errors, many of which, unfortunately, were reproduced by Ersch, librarian of the university at Jena, in his enlarged publication of 1797–1806, a work in other respects of solid merit and utility. The *Dictionnaire des Anonymes* of the Abbé Duclos is serviceable but incomplete; it has been abridged by Fournier in his *Dictionnaire portatif de Bibliographie*, Paris, 1805.

Among later authorities may be mentioned Weller's *Maskirte Literatur der alteren und neueren Sprachen*, Leipsic, 1858, and *Die falschen und fingirten Druckorte*, 1858, and the *Dictionnaire des Pseudonymes*, by G. Heilly, 1869. Conspicuous in merit is the *Dictionnaire des Ouvrages Anonymes et Pseudonymes*, by M. Barbier, librarian to Napoleon I., the last edition of which is as recent as 1872. It comprises a vast number of articles, but the plan does not extend to foreign productions, except those which have been translated into French. His labours have been supplemented and improved upon by De Manne, in his *Nouveau Dictionnaire* of 1868, and by Quérard in his *Supercheries littéraires dévoilées* 1847–53. The list of anonymous writers in France includes Pascal, La Rochefoucauld, and Cardinal Richelieu. The authorship of Montesquieu's *Esprit des Lois* was disguised, on its appearance in 1748, as was the *Anti-Machiavel*, written by Frederick II. of Prussia, and published by Voltaire, who himself wrote several works anonymously. For Italian literature there are Vinc. Lancetti's *Pseudonima*, published at Milan in 1836; and Melzi's *Dizionario di Opere Anonime e Pseudonime di Scrittori Italiani*, Milan, 1848-59.[2] In England the practice of anonymous writing, in spite of the example of journalism, has never largely prevailed; but the *Letters of Junius* are a conspicuous example of authorship successfully concealed. The *Ecce Homo* is a recent instance among the works of current celebrity. The *Handbook of Fictitious Names*, by Olphar Hamst, London, 1868, is a useful and amusing guide, especially to English authors of the lighter literature of this century. Works of this class, however, are most applicable to countries in which the liberty of the press has been most restricted.

VI. *Condemned and Prohibited Books.*

Books supposed hurtful to the interests of government, religion, or morality have been sometimes condemned to the flames, sometimes censured by particular tribunals, and sometimes suppressed. Such methods of destruction have been followed in various countries, with regard both to their own and to foreign productions; and lists have been published from time to time of the works so interdicted.

Heathen antiquity supplies some instances of the burning of obnoxious books, such as the reported destruction of the works of Protagoras at Athens, and of astrological works, as well as the writings of Labienus, by Augustus at Rome. Some Greek works, alleged to have been found in the tomb of Numa in 181 B.C., and ascribed to him, were burnt by order of the Senate; the story of their discovery, however, is a mere fabrication. Tacitus mentions a *History* by Cremutius Cordus, which the Senate, to flatter Tiberius, condemned, because it designated C. Cassius the last of the Romans.[3] Diocletian, according to Eusebius, caused the Scriptures to be burnt, but the early Christian Church was not slow in following the example of intolerance, and the charge of heresy was a ready instrument for putting down works alleged to be injurious to the faith. The first recorded instance is that of Arius, whose writings were condemned to the flames at the Council of Nicæa, Constantine himself threatening with death those who should harbour any copies. The same fate befell the works of Nestorius at the Council of Ephesus, and those of Eutyches at Chalcedon. Pagan works were prohibited at the Council of Carthage in 400. Aristotle was forbidden by the church in the 13th century, but the restriction was relaxed in favour of the universities by Pope Nicholas V. A list of prohibited books is found in a decree of a council at Rome as early as 494.[4] But the chief rigours of persecution began with the Inquisition, and the crusade against literature increased in severity with the multiplication of books through the press. In 1515 the Council of Lateran at Rome appointed clerical censors to examine all works before publication, as if, to use Milton's indignant remonstrance, "St Peter had bequeathed to them the keys of the

[1] Quérard's *France Littéraire*, Paris, 1846, contains a copious list of such works from 1700 to 1845.

[2] See Petzholdt's chapter on "Maskirte Literatur," in his *Bibliotheca Bibliographica*.

[3] See the chapter on "Book-Censors" in Beckmann's *History of Inventions*.

[4] Labbe's *Conc.* ii., col. 938–94.

press as well as of Paradise."[1] In 1543 Caraffa issued an order that no book should be printed without leave from the Inquisition, and booksellers were, accordingly, required to send in catalogues. Brunet mentions, however, a list of prohibited authors, prepared by order of Charles V., which was printed at Brussels in 1540, and is the earliest of its kind. An *Index generalis scriptorum interdictorum* was published by the Inquisition at Venice in 1543, and similar catalogues followed from the universities of Paris and Louvain. The first Index of the Court of Rome appeared in 1558, and was reprinted in 1559. The subject was discussed at the Council of Trent, who delegated the right of supervision to the Pope, and the result was the *Index Tridentinus* of Pius IV.,—the first strictly Papal Index,—which was printed by Aldus at Rome in 1564. Thence began a long series of literary proscriptions, which was continued by the Congregation of the Index,[2] and of which one of the immediate effects was to drive printing to Switzerland and Germany. The right of dictating what books should or should not be read was a consequence of the claims of the Papacy over the conscience and morals of mankind; and the vitality of persecution has been preserved within the Romish Church by the consistent exercise of such pretensions. The bibliography of these Expurgatory Indexes has been copiously treated.[3] Among the earlier victims were Galileo and Copernicus; and English literature is represented by such names as Gibbon, Robertson, Bacon, Hallam, Milton, Locke, Whately, and J. Stuart Mill. In Spain the power of the Inquisition, provoked by the invasion of Lutheranism, was wielded by Fernando de Valdes, whose catalogue of 1559 formed the model of that issued by Pius IV. in the same year. An edict of Philip II. was published at Antwerp in 1570, and a general Index of all books suppressed by royal authority appeared at Madrid in 1790. It is noticeable that Smith's *Wealth of Nations* has been proscribed in that country, "on account of the lowness of its style and the looseness of its morals." A list of books suppressed in France between 1814 and 1850 has been edited by Pillet. For the more general notices of prohibited literature, we refer our readers to Klotz's *De Libris auctoribus suis fatalibus*, 1761; to Struvius's *Bibliotheca Hist. Litter.* vol. iii. c. 9; to the Dissertations in the seventh volume of Schelhorn's *Amœnitates Literariæ*, which contain much curious information; to Brunet's *Livres Supprimés et Condamnés;* and to Peignot's *Dictionnaire Critique et Bibliographique des principaux Livres condamnes au feu, supprimés, ou censurés*, 2 vols., Paris, 1806. This last work is agreeably written, and gives a copious list of authorities on the subject; but its enumeration of *principal* works is far from complete, and comparatively few English books are mentioned.

A comprehensive account of works condemned or suppressed in England has yet to be written, but an article in the *Edinburgh Review*[4] supplies some interesting materials on this subject. Peacock's *Precursor*, which the author burnt with his own hand, is an early instance, before the invention of printing. The "war against books,"[5] however, began under Henry VIII., the suddenness of whose breach with Rome is shown by the circumstance that, whereas in 1526 anti-popery books were condemned as heretical, in 1535 all books favouring popery were decreed to be seditious. Several of the early translations of the Bible were suppressed,—Tyndal's version among others. As many copies of that work as the superior clergy could buy up, were publicly burnt at St Paul's on Shrove Tuesday, 1527, Fisher, bishop of Rochester, preaching a sermon on the occasion. An edition of the Bible was suppressed for a misprint, the printer having omitted the word "not" in the seventh commandment, but a copy survives in the Bodleian. A general burning of unlicensed books was ordered by the king in 1530, the *Supplication of Beggars*, a well-known invective against Wolsey, being included in the list. Another catalogue was issued in 1546 by proclamation, and the Act 3 and 4 Edward VI. made a raid against missals and books of devotion. The regulations of the Star Chamber in 1585 claimed the power of licensing and seizing books, and their scrutiny was as rigorous as that of the Inquisition. Nevertheless the reign of Elizabeth was fruitful in "schismatic and libellous tracts."[6] A notable offender was Cardinal Allen's *Admonition*, containing a furious attack on the queen, of which a copy remains in the British Museum; and the famous Martin-Marprelate tracts raised a storm of opposition. In 1607 Dr Cowell's *Law Dictionary* was burnt by order of the House of Commons, for its assertions of divine right in favour of James I.; and the *King's Book of Sports* incurred the same fate at the hands of the Puritans in 1644. The persecutions of the Star Chamber include the punishment of Prynne for his *Histriomastix*, and the still more barbarous mutilation of Dr Alexander Leighton for his two works, *The Looking Glass of the Holy War*, 1624, and *Zion's Plea against the Prelacy*, 1628. Milton's Εἰκονοκλάστης and the *Defensio pro Populo Anglicano* were suppressed after the Restoration. Defoe's *Shortest Way with the Dissenters* was burnt by Parliament in 1703; and sixty years later Wilkes's *North Briton* incurred the same fate. The last instance of authorized book-burning in Great Britain was in 1779, when the *Commercial Restraints of Ireland considered*, by the Hon. Hely Hutchinson, was given to the flames.

This branch of bibliography has a peculiar interest to the literary historian. It serves to indicate, for the most part, periods of political excitement or religious intolerance. Fortunately, however, the efficacy of persecution has been frustrated by the disseminating power of the press. *Punitis ingeniis, gliscit auctoritas*, is the reflection of Tacitus; and experience has abundantly proved that it is easier to destroy an author than his book. Melancholy as are the records of literary martyrdom, there remains this satisfaction that, in the main, the policy of oppression has defeated its own ends.

VII. *Catalogues and Bibliographical Dictionaries.*

The first catalogues, after the invention of printing, were those of the early printers, who, as booksellers, published sale-lists of their works, to attract the attention of the learned. The most ancient of these *catalogi officinales*—the humble predecessors of Bohn's gigantic catalogue—is a simple leaf, entitled *Libri Græci impressi*, printed by Aldus in 1498. The list consists of fourteen articles, distributed into five classes,—grammar, poetry, logic,

[1] *Liberty of Unlicensed Printing.*

[2] A complete list of their catalogues is given in Petzholdt's *Bibl. Bibliogr.*, "Verbotene Literatur."

[3] See the *Index Librorum prohibitorum a Pontificis auctoritate, in usum Bibliothecæ Bodleianæ*, by Tho. James, 1627; Francus, *De Papistarum Indicibus*, Leipsic, 1684; *Thesaurus Bibliographicus ex Indicibus Librorum prohibitorum congestus*, Dresden, 1743. Carnot, in 1826, published a complete list of all books condemned by the court of Rome from the date of printing to 1825, with the dates and decrees of their condemnation. The best known, though not the latest, edition of the *Index* was issued by Pius VII. in 1819.

[4] "Suppressed and Censured Books," vol. cxxxiv. July 1871.

[5] See the final chapter in Disraeli's *Amenities of Literature.* A curious list of Lutheran works prohibited in England is given in Strype's *Eccl. Memorials*, i. 165.

[6] The registers of the Stationers' Company contain entries of books ordered for "immediate conflagration" in 1599. See *Notes and Queries*, 3d series, xii. 436. Volume ii. of Wood's *Athen. Oxon.* was burnt at Oxford in 1693 by the apparitor of the university, for some alleged reflections on the memory of Lord Clarendon.

philosophy, and theology, and may be regarded as one of the first attempts to apply a system of classification to printed books. Its interest is enhanced by its containing the price of the books advertised for sale. The increasing commerce in literature was at once a cause and a consequence of similar catalogues; and the example of Aldus was followed by the Stephens, and by Colines, Wecholl, and Vascosan, and other French printers of the first half of the 16th century, whose lists are given in vols. ii. and iii. of Maittaire's *Annales Typographici*, the divisions of subjects increasing with the spread of printed literature. In England the earliest known sale-list of printed books was published by Andrew Maunsell, a London bookseller, in 1595, and contains the titles of many works now lost or forgotten. In 1554 or 1564[1] appeared the first printed catalogue of the Frankfort book-fair, published by George Weller, a bookseller of Augsburg; and in 1604 it was followed by the general Easter catalogue, printed by permission of the Government. These catalogues of the different book-fairs were collected together in 1592 by Cless—whose researches included all books printed since 1500—and by Draudius in his *Bibliotheca Classica* (1611). The same has been done by Georgi in his *Bücher Lexicon* (1758), a catalogue of all works printed in Europe up to 1750.

The growth of the book-trade naturally promoted the spread of collections; and towards the end of the 17th, and especially during the 18th century, book-catalogues of every description multiplied rapidly. Their progress is copiously treated of in Nichols's *Literary Anecdotes*, vol. iii. pp. 608–693.[2] Most private collections, at first, appear to have been bought and sold *en bloc;* and it was through the catalogues, compiled in many instances by learned and well-qualified librarians, that a more critical and discriminating estimate of their contents was formed. P. Garnier in 1678 prepared an excellent catalogue of the library of the Jesuit Collége de Clermont at Paris, using the materials, like other bibliographers after him, for a classified system of his own. Dr Johnston and Oldys were the joint editors of the *Bibliotheca Harleiana*, which they prepared for Osborne the bookseller, who bought the library of the earl of Oxford; and Maittaire drew the scheme of arrangement. The earliest catalogues of public libraries were simple inventories, disposed in alphabetical order, with, at most, a few biographical notices interspersed; yet they paved the way, in the hands of Conrad Gesner, for the study of "pure" bibliography. The compilation of *catalogues raisonnés* was deferred till the 18th century, when the labours of French librarians or booksellers, such as Piget, Prosper Marchand, Martin, Barrois, Baillet, and the De Bures, created by that means a public taste for books. The greatest work of this kind was the French *Bibliothèque Royale*, begun in 1739, and finished in 10 vols. in 1753. Part i., relating to printed books, was superintended by the Abbés Sallier and Boudot. In a perfect *catalogue raisonné* alphabetical arrangement is dispensed with; every work occupies its proper place in regard to the light it throws on the subject treated, and the ground traversed by the author. "Catalogues of this sort," says Dibdin, "are to bibliographers what reports are to lawyers;" and Maittaire terms them "proces-verbaux litteraires, servant à decider une infinité de questions qui s'élèvent sur la bibliologie." The consolidation of these detached catalogues was a consequence of the increased requirements of learning, and the *Bibliothecæ*, or registers of particular libraries, supplied the first materials for a general dictionary of reference. Bibliography, thus represented, is the *codex diplomaticus* of literary history, with a field of research co-extensive with the innumerable productions of the press. But a universal dictionary of this kind is but a dream of bibliographers; nor would any single compiler be equal to the task. The *Bibliotheca Universalis* of Gesner in 1545 is the earliest and almost the only effort of this nature. His work professed to include the titles of all known books, existing or lost, but he confined himself to those in Hebrew, Greek, and Latin. The first volume is classed alphabetically, according to the authors' names; the second contains a distribution of subjects, and is divided into nineteen books. Balthazar Ostern, in 1625, published a *Bibliothèque Universelle*, or catalogue of printed books from 1500 to 1624. A general survey of printed literature might be made to the end of the 16th century; but the idea is now wholly chimerical, since the number of books surpasses all human calculation. The *Bibliotheca Britannica, or General Index of British and Foreign Literature*, by Dr Watt of Glasgow, published in 1824, 4 vols., is perhaps the nearest modern exposition of Gesner's idea. All so-called general dictionaries are, in fact, written on a selective principle of some kind, the only means, as Baron de Reiffenberg remarks, of achieving utility and completeness. Ersch, the founder of modern bibliography in Germany, published his *Allgemeines Repertorium der Literatur* in 1793–1809; but the first really comprehensive work in that country was Ebert's *Allgemeines Bibliographisches Lexicon*, Leipsic, 1821–1830, an English translation of which was printed at Oxford in 1837, 4 vols. 8vo. Kaiser's *Vollstandiges Bucherlexicon*, and Heinsius's *Allgemeines Bucherlexicon*, with the continuation by Schultz, are useful works of reference; but their contents, as might be expected, are far from justifying the epithet of universal. Osmont, Cailleau, and other French compilers on a large scale, limited their notices to rare and remarkable books; and De Bure in his *Bibliographie Instructive* only included productions of inferior repute, because his original materials were too scanty to illustrate all the divisions of a complete system and comprise what he termed a "Corps de Bibliographie choisie." Brunet's *Manuel du Libraire* was the first work which embraced in alphabetical order what was most precious in the literature of all times and nations. It was first published in three volumes, 8vo, in 1810, and has since passed through several editions. It is far richer in English and German books than any of the preceding compilations, and its plan is such as to afford all the advantages both of a dictionary and a classed catalogue. As a practical work of reference, whether to the bibliographer or the student, it is the most complete dictionary yet published on a scale so comprehensive. The *Bibliographie Universelle* (Manuels-Roret), Paris, 1857, contains a copious list of the leading works on the different subjects of learning, which are arranged in alphabetical order, and a succinct summary of the principal editions of an author's work, including the ancient classics. Among works avowedly devoted to *special* bibliography, some are limited to the productions of certain epochs. The first century of printing has been an attractive subject of research, as has been noticed above in the chapter on early printed books. The *Bibliographie de la France* was the first trustworthy compilation of annual literature in that country. Of more immediate value for purely literary purposes are those dictionaries or catalogues which are restricted to particular branches of knowledge; and they have the advantage of being able to ensure greater fulness and accuracy, from the limited scope of their contents, than is available in a work professedly general. "Through the want of such," said Oldys, "how many authors have we who are consuming

[1] Le Mire (Miræus), as quoted by Fabricius, says 1554; Labbe, Reimann, and Heumann, quoting from the same source, say 1564.

[2] See also Cailleau's *Dict. Bibliographique;* Dibdin's *Bibliomania*, 95–193, *notes;* and the "Catalogue des Bibliothèques Particulières" at the end of *Bibliog. Universelle* (Manuels-Roret), Paris, 1857.

their time, their quiet, and their wits, in searching for either what is past finding, or already found." A catalogue, in short, might be made of superfluous writings by authors who have dug in mines of literature already exhausted. The tendency, however, of modern bibliography is fortunately to subdivide the field of literature; and the student of any special department of learning need be at no loss for authorities to consult. Bale's *Illustrium Majoris Britanniæ Scriptorum Summarium* (1458), John Pits's *De Academicis et Illustribus Angliæ Scriptoribus* (1619), Bishop Tanner's *Bibliotheca Britannico-Hibernica* (1748), and Nicolson's *Historical Libraries*, 4to, 1776, are the earliest catalogues, on a large scale, of our national literature. A list of Saxon writers, by Wanley, forms the second volume of Hickes's *Thesaurus*. *A Critical Dictionary of English Literature and British and American Authors*, by S. A. Allibone, 3 vols., 1859–1872, is an industrious work. The *Bibliographer's Manual of English Literature*, by W. T. Lowndes, is indispensable to the collector; and for a first attempt of the kind, displays a singular degree of accuracy and research. His *British Librarian, or Book Collector's Guide*, 1839, purported to give a classed catalogue of books on English literature printed in Great Britain; he lived, however, to complete only six numbers of the division—*Religion and its History*. Dr Adam Clarke's *Bibliographical Dictionary*, 6 vols. 1803, is restricted to works in the learned and Eastern languages; his *Bibliographical Miscellany*, published in 1806 as a supplement, contains, among other matter, a full account of the English translations of the classics. To foreign literature belong, among others, Quérard's *La France Littéraire*, and the *Bibliothèque Historique* of Le Long; the *Bibliotheca Belgica* of J. F. Foppens, 2 vols., 1739: *Bibliotheca Hispana, Nova et Vetus*, by Nicholas Antonio, 1783–88; Haym's *Biblioteca Italiana;* Worm's *Danske, Norske, og Islandske Lærde Lexicon*, 1771–84; Nyerup and Kraft's *Almindeligt Litteratur Lexicon*, 2 vols., 1820; Georgi's *Allgemeines Europaisches Bucher-Lexicon*, 1742–58; and others which space forbids us to enumerate.

The works devoted to special branches of knowledge form a host in themselves, and we can only mention a few of them, by way of illustration. To theology belong such works as Le Long's *Bibliotheca Sacra*, 1723, and the *Bibliotheca Theologia Selecta*, by Walchius, 1757, as well as his *Bibliotheca Patristica*, new edition, 1834. Judaic literature is represented by Furst, and Hebrew writers by Wolfius, 1715–33. Lipenius, a learned German divine of the 17th century, devoted separate *Bibliothecæ* to theology, law, philosophy, and medicine, which were collected in his *Bibliotheca Realis*. His *Bibliotheca Juridica* has received several supplements by other writers, and is much the most valuable of his series. Bridgman's *Legal Bibliography*, and the valuable work of M. Camus, *Lettres sur la profession d'Avocat et Bibliothèque choisie des Livres de Droit*, deserve especial notice. The *Bibliotheca Historica* of Meusel relates to historical works of all ages and nations. An excellent catalogue of books of voyages and travel is given in the *Bibliothèque Universelle des Voyages*, by M. Boucher de la Richarderie, 6 vols., Paris, 1808. Dr Young's *Catalogue of Works relating to Natural Philosophy*, the *Catalogus Bibliothecæ Historiæ Naturalis Josephi Banks*, by Dr Dryander, and Engelmann's *Bibliotheca Historico-naturalis*, Leipsic, 1846 (supplement, 1861); the *Bibliotheca Mathematica* of Murhard, Lalande's *Bibliographie Astronomique*, and the *Bibliographie Agronomique*, are leading works, written on the same principle of selection. British Topography was treated by Gough in 1780, and by Upcott in 1818. Nisard's *Histoire des Livres populaires, ou de la Littérature du Colportage*, 1854, a curious and amusing work, may also be mentioned. Œttinger's *Bibliographie Biographique* contains a copious catalogue of purely biographical works.

For a comprehensive work of reference on special biographies we cannot do better than refer our readers to the *Bibliotheca Bibliographica*, by Dr Julius Petzholdt, Leipsic, 1866. Part i. relates to works on bibliography; part ii. to the bibliography of different nations; and part iii. to works connected with special branches of learning, which are classified into leading divisions. The *Répertoire Bibliographique Universel* of M. Peignot is a useful but ill-arranged work; it dates back, moreover, to 1812. The progress of knowledge and research, especially with regard to scientific subjects, obviously throws works of this description soon out of date to the student, who desires to be acquainted with the most recent as well as the earlier authorities. As landmarks, however, of the state of knowledge at different epochs, they are full of interest to the literary bibliographer.

VIII. *On the Classification of Books.*

The different methods, adopted from time to time, of classing books according to their subject matter, has occasioned a variety of so-called *systems* of bibliography, which it is important to notice, but which space forbids us to describe in detail. A distinction must be observed between a scheme of arrangement applied to a particular library, and limited therefore by its contents, and one which embraces in its divisions and subdivisions the entire range of literature. Nothing, on either head, is learnt from the Greeks and Romans; the classed catalogue of the library of St Emmeran at Ratisbon, compiled in 1347, and containing twelve divisions, is cited as the earliest specimen of its kind. (See LIBRARIES.) The most ancient system, in the wider sense of the term, is ascribed to the Chinese, who in the 13th century distributed the field of human knowledge into classes numbering from fourteen to twenty, with sectional subdivisions to each.

Classified systems suggested by or devised for particular libraries after printing had multiplied their contents, originated chiefly with librarians or compilers of catalogues. In 1587 Jean Baptiste Cardona wrote four treatises on the principal libraries of his day. His description of the library of the Escorial was followed in 1635 by Arias Montanus, whose catalogue divided the books there according to languages, separating MSS. from printed works, and distributed the whole into sixty-four classes. Their number was reduced by Casiri in his *Bibliothèque Arabico-Espagnole de l'Escurial*, Madrid, 1760. In 1631 John Rhodius proposed a scheme for the arrangement of the university library at Padua, which has been recently published in the *Serapeum* by Dr Hoffman, from a manuscript found in the town library at Hamburg, under the title of *Ein bibliothekarisches Gutachten abgegeben im Jahre*, 1631. His method is very similar to that of Claudius Clement, in his *Musei sive Bibliothecæ tam privatæ quam publicæ exstructio, instructio, curæ usus*, 1635. A catalogue of the library of the Canon de Cordes, which was purchased by Mazarin, was compiled in 1643 by his librarian, Gabriel Naudé, whose *Addition à la vive de Louis XI.* contains much curious matter on bibliography, but who is best known, perhaps, from his defence of the massacre of St Bartholomew. His *Dissertatio de instruenda Bibliotheca* had previously appeared in 1627 in a French version, entitled *Avis pour dresser une Bibliothèque*, an English translation of which was published by John Evelyn in 1661; it was followed by several treatises of the same kind, containing minute instructions to librarians.[1]

[1] David Köller's *Sylloge aliquot scriptorum de bene ordinanda et ornanda bibliotheca*, 1728, contains a full account of authorities up to

F. Rostgaard published in 1697 a *Projet d'une nouvelle méthode pour dresser un catalogue*, which serves to illustrate the difference between arranging a catalogue and a library. Naudé finds fault with the far-fetched refinements of his predecessors, and his divisions have the merit of being more simple and precise. "It is certain," says Mr Edwards, "that a good catalogue will require a much more minute classification than would be either useful or practicable in the presses of a library."[1] A confusion between these two distinct objects has largely pervaded the "system" of even later writers, who have supposed the same nicety and exactness to be equally necessary and equally practicable in both. Where there is a classed catalogue, the grand objects of a systematic arrangement are sufficiently provided for, independently of the location of the books on which so much fanciful lore has been expended. If there be no classed catalogue, it is tolerably clear that, for purposes of convenient and ready reference, a minute classification of books on the shelves, however accurate, may tend only to bewilder and confuse. Simplicity is the readiest means to aid the memory and abridge the labour of the librarian; and this object can be obtained by a much more elementary division of books than could be tolerated in any classified catalogue extending to details.

These remarks apply largely to the ordinary system of modern French bibliographers, the origin of which is variously ascribed to Bouillaud, Garnier, and Martin. Priority of date appears to belong to Bouillaud, for his *Bibliotheca Thuana*, or sale-catalogue of the famous library of De Thou, had existed in MS. some time before it was edited by Quesnel in 1679. His system embraces five classes, theology, jurisprudence, history, philosophy, and literature,—the last including heterodox and miscellaneous works. The catalogue by P. Garnier of the library of Clermont, entitled *Systema Bibliothecæ Collegii Parisiensis Societatis Jesu*, was published two years previously. The headings embrace 461 subdivisions, of which 74 belong to theology, 88 to philosophy (a class clumsily and confusedly arranged), 227 to history, and 72 to jurisprudence. In 1709 appeared Prosper Marchand's system, developed in his *Catalogus bibliothecæ Joachimi Faultrier*. In his preface he attacks the system of Naudé, and, after treating of the different methods, viz., the order of nature, of nations, of languages, of time, and alphabetical, sums up his divisions into theology, or divine knowledge; philosophy, or human knowledge, separated into belles lettres and sciences; and history, or the knowledge of events. Bouillaud's system as modified by Marchand, was adopted by Gabriel Martin in most of the catalogues, amounting to nearly 150, which he published between 1711 and 1760, and afterwards, with some enlargement of subdivisions, by De Bure in his *Bibliographie Instructive*. The result of their successive labours, which is known as "the system of the Paris booksellers," is the one commonly adopted in France, and consists of theology, jurisprudence, sciences and arts, literature, and history. Some changes, it is true, were afterwards proposed. M. Ameilhon, in a paper published in 1799 in the *Memoirs* of the French Institute, suggested as primitive classes,—grammar, logic, morals, jurisprudence, metaphysics, physics, arts, belles lettres, and history,—his Revolutionary sympathies inducing him to discard theology from the list. But the system, finally elaborated by Martin, survived to govern the classification of the principal libraries in his country. Of the various innovations, the system of Daunou in his *Mémoire sur la Classification des Livres d'une grande Bibliothèque*, 1800, is frequently cited as the best. Since then the Paris scheme has been modified by bibliographers like Barbier, Achard, and Brunet; by M. Merlin in his catalogue of the library of Baron Silvestre de Sacy (1842); and by M. Albert, in his *Récherches sur les principes fondamentaux de la classification d'une Bibliothèque*, Paris, 1847. Olenin's system (1808), for the Imperial library at St Petersburg, separated sciences from arts, and introduced philology as a distinct class. Dr Conyers Middleton in 1723 submitted a scheme to the senate of Cambridge for the classification of the university library; the classes proposed by him being these—theology, history, jurisprudence, philosophy, mathematics, natural history, medicine, belles lettres (*literæ humaniores*), and miscellaneous. Hartwell Horne's *Outlines for the Classification of a library*, based on the Paris system, were submitted about the same time to the Trustees of the British Museum. A serviceable "Scheme for Town Libraries" is embodied in the chapter of Mr Edward's book previously quoted.

Of the more general "systems," based on a survey of the field of human knowledge, and not immediately directed to the requirements of a library, a brief notice must suffice. The earliest system, in this sense of the word, is commonly ascribed to Conrad Gesner, the founder, as Dibdin calls him, of pure bibliography. Yet he was, in fact, preceded, however feebly, by Alexo Vanegas, whose work, published at Toledo in 1540, forms the first imperfect type of future efforts of that kind. His divisions are fourfold, viz.: "*Original*—of the harmony between predestination and free will; *Natural*—of the philosophy of the visible world; *Rational*—of the function and use of reason; *Revealed*—of the authority of the Scriptures." Gesner's, however, was the first comprehensive attempt at a general encyclopædia of literature, constructed in the form of a catalogue. His system was first published in 1548 as an index of matters to his *Bibliotheca Universalis*, under the title of *Pandectarum sive Partitionum Universalium Libri XXI.*[2] Florian Trefler, a Bavarian Benedictine, published at Augsburg in 1560 a *Méthode de classer les Livres*, which Peignot describes as "plus que mediocre." In 1587 appeared the *Tableaux accomplis de tous les arts libéraux*, by Christofle de Savigny, which Brunet asserts was the model of Bacon's "Encyclopædical Tree," but which was substantially the system of Gesner. The well-known speculations of Bacon as to the genealogy of knowledge were embodied by D'Alembert in his *Discours préliminaire à l'Encyclopédie Méthodique*, Amst., 1767. They were also made the basis of other schemes by Regnault-Warin, Laire, Ferrario, and especially Peignot, whose system was divided into three primitive classes, viz., history, philosophy, and imagination, with the addition of bibliography, as an introductory class. Girard's system was embodied in an *Encyclopédie ou Dictionnaire raisonné des Sciences, des Arts, et des Métiers*, edited in 1751 by Diderot and d'Alembert, the latter of whom undertook the part relating to mathematics. Camus in 1798 took man in a state of nature, and then classed his library in the order in which this "man of nature" is supposed to form his impressions of the universe. The divisions of Thiébaut in 1802 comprised—(1), Connaissances instrumentales; (2), Connaissances essentielles; and (3), Connaissances de convenances, and were founded on a somewhat similar principle to that adopted in 1822 by the Marquis Fortia d'Urban, in his *Nouveau Système de Bibliographie alphabétique*, who prefaced his classes with

that date. A chapter of Morhof's *Polyhistor* is devoted to the same subject. See also Leibnitz, *Op. Omn.*, ed. 1768, vol. v.; and Baillet's *Jugemens des Savans*. Aimé Martin's *Plan d'une Bibliothèque Universelle* appeared in 1837.

[1] E. Edwards, *Memoirs of Libraries*, ii. 783. See his chapter on "Classificatory Systems."

[2] For a full account, see the article "Gesner" by Cuvier, in the *Biographie Universelle*. His *Bibliotheca* was reprinted, and greatly enlarged, by Simler, in 1574. Conrad Lycosthenes afterwards published an abridgment, and a supplement was added by Verdier.

encyclopædias. Ampère, in 1834, in his *Essai sur la Philosophie des Sciences*, has disfigured his system with a needlessly technical nomenclature.

Much unnecessary refinement has been expended by German writers on this subject. The system of Leibnitz, however, in 1718, is well suited to practical purposes. His leading classes are these—theology, jurisprudence, medicine, intellectual philosophy, mathematics, natural philosophy, philology, history, and miscellaneous.[1] The scheme of the *Jena Repertorium*, published in 1793, contains 16 primitive classes, and no less than 1200 subdivisions. The system of Denis, formerly keeper of the imperial library at Vienna, was developed in his *Einleitung in die Bücherkunde*, 2d edition, 1795; he classifies learning into theology, jurisprudence, philosophy, medicine, mathematics, history, and philology. Krug's system followed in 1796, and Schleiermacher's in 1852. Wuttig's *Universal-Bibliographie*, 1862, aimed at embracing in a systematic survey the collected literature of the current time.

In England the classification of learning has been treated as a branch of philosophy rather than of bibliography. Locke's *Essay on the Human Understanding* contains, in book iv. c. 21, a "Division of the Sciences;" and Bentham has an "Essay on Nomenclature and Classification" in his *Chrestomathia*, though it does not appear that he intended it to apply to the distribution of books. Coleridge, in his *Universal Dictionary of Knowledge*, 1817, aimed at combining the advantages of a philosophical and alphabetical arrangement, and adopted four leading classes, viz.,—pure sciences, mixed sciences, history, and literature, including philology. Lord Lindsay's *Progression by Antagonism*, 1845, contains another method, based on his theory of the divisions of human thought.

For further information on this branch of the subject the reader is referred to Peignot's article on "Système" in his *Dictionnaire de Bibliologie*, and especially to the chapter on "Bibliographical Systems" in Petzholdt's *Bibliotheca Bibliographica*, Leipsic, 1866. Many of the above-named schemes, particularly those of high, philosophical pretensions, are fanciful in theory, and quite unsuited to the practical requirements of a catalogue of reference. The seven classes of Denis were based on the words of Solomon, "Wisdom hath builded a house; she hath hewn out her seven pillars;" and Naudé mentions a writer who proposed to class all sorts of books under the three heads of morals, sciences, and devotion; and who assigned, as the grounds of this arrangement, the words of the Psalmist, *Disciplinam, Bonitatem et Scientiam doce me.* There are obvious objections to all bibliographical systems which aspire to follow the genesis and remote affinities of the different branches of knowledge. The truth is that, when bibliographers speculate in this field with a view to catalogue-making, they entirely forget their proper province and objects. The compilation of a good catalogue of an extensive library is quite difficult enough, without indulging in refined abstractions on the genealogy of human knowledge.

As regards works and collections which cannot with propriety be limited to any one division of knowledge, it would be advisable to refer them to an additional or *miscellaneous* class, as has, in fact, been done by some writers. Camus proposes to enter such works in the class in which their authors most excelled; but this plan would obviously produce much confusion. While, however, a miscellaneous class might properly indicate the collective editions of an author's works, yet his separate treatises should be entered under the subjects to which they belong. A system of cross-reference is in many cases unavoidable, if completeness of general design is to be combined with the cardinal object of a classed catalogue, namely, that of showing what has been written by the authors specified therein on the different branches of knowledge as they may be best arranged.

[1] Idea Leibnitiana Bibliothecæ Publicæ secundum classes scientiarum ordinandæ (*Works*, vol. v.)

IX. *Bibliography in General.*

It has been our object in this article to institute such a division of the subject, as should enable us to point out the best sources of information in regard to all its branches. Some works still remain to be noticed which treat generally of all matters relating to bibliography, though their scope and purpose differ according to the view of the science adopted by the writer. A comprehensive and judicious digest of bibliographical lore is still wanted, but there are several works which may be consulted with advantage. Cailleau's *Essai de Bibliographie*, appended to his *Dictionnaire* of 1790, is an interesting treatise. The *Einleitung in Die Bücherkunde* of M. Denis, 1795–96, is an excellent work divided into two parts, the first of them relating to bibliography, and the second to literary history. The *Traité Élémentaire de Bibliographie*, by S. Boulard, Paris, 1806, was intended to serve as an introduction to all works on that subject written up to the date of its appearance. The labours of Peignot, besides his works on suppressed and rare books already noticed, include (1), the *Manuel Bibliographique, ou Essai sur la connoissance des livres, des formats, des éditions, de la manière de composer une Bibliothèque, etc.*, 1801; and (2), the *Dictionnaire raisonné de Bibliologie*, 2 vols. 8vo, 1802. The plan of this work, as Brunet admits, is well conceived, and furnishes a convenient mode of reference. Bibliography is certainly indebted to this industrious compiler, but his details have in many respects been rendered obsolete by subsequent research, and his vague notions of the scope and objects of his study have frequently led him into confusion and extravagance. A *Manuel du Bibliophile*, by the same author, appeared a Dijon in 1823. The *Cours Élémentaire de Bibliographie*, by C. F. Achard, Marseilles, 3 vols. 8vo, 1807, derives its chief value from its excellent summary of the different systems of classification applied to books. We learn from the introduction, that M. François de Neufchâteau, when Minister of the Interior, ordered the librarians of all the departments to deliver lectures on bibliography, but that the plan, which indeed appears fanciful, entirely failed, the librarians having been found quite incapable of prelecting upon their vocation. The *Introduction to the Study of Bibliography*, by Thos. Hartwell Horne, 2 vols. in 1, 8vo, London, 1814, is perhaps the most useful book of this kind in the English language, though the compiler would have done better to restrict himself to printed books, instead of ranging discursively over the whole field of MS. literature. His book is chiefly translated and compiled from French bibliographical works, and will be found useful to those who have not access to them. Besides some excellent specimens of early typography, it contains full lists of authorities on bibliography and literary history, and a copious account of libraries both British and foreign. The *Studio Bibliographico*, by Vincenzo Mortillaro, Palermo, 1832, is an Italian treatise of considerable merit. P. Namur's *Bibliographie palæographico-diplomatico-bibliogique*, Liége, 1838, embraces many subjects outside the province of bibliography proper. The *Librarian's Manual*, by Reuben A. Guild, New York, 1858, is a compendious book of reference for the student in search of authorities. Enough has been said to show that the different branches of bibliography have been treated with considerable industry; but there is room for further effort, if bibliographers will recognise the chief value of their science as the handmaid of literature. (E. F. T.)

BIBULUS. The best-known of those who bore this surname, which belonged to the Gens Calpurnia at Rome, was Marcus Calpurnius Bibulus, elected consul with Julius Cæsar, 59 B.C. He was the candidate put forward by the aristocratical party in opposition to L. Lucceius, who was of the party of Cæsar; and bribery was freely used (with the approval, says Suetonius, of even the rigid Cato) to secure his election. But he proved no match for his able colleague. He made an attempt to oppose the agrarian law introduced by Cæsar for distributing the lands of Campania, but was overpowered and even personally ill-treated by the violence of the mob. After making vain complaints in the senate, he shut himself up in his own house during the remaining eight months of his consulship, taking no part in public business beyond fulminating edicts against Cæsar's proceedings, which only provoked an attack upon his house by a mob of Cæsar's partizans. When the interests of Cæsar and Pompey became divided, Bibulus supported the latter, and joined in proposing his election as sole consul (52 B.C.) Next year he went into Syria as proconsul, and claimed credit for a victory gained by one of his officers over the Parthians, who had invaded the province, but which took place before his own arrival in the country. After the expiration of his government there, Pompey gave him the command of his fleet in the Ionian Sea. Here also he proved himself utterly incapable; distinguishing himself chiefly by the cruel burning, with all their crews on board, of thirty transport vessels which had conveyed Cæsar from Brundisium to the coast of Epirus, and which he had captured on their return, having failed to prevent their passage. He died soon afterwards of fatigue and mortification. By his wife Portia, daughter of Cato, afterwards married to Brutus, he had three sons. The two eldest were murdered in Egypt by some of the soldiery of Gabinius; the youngest, Lucius Calpurnius Bibulus, fought on the side of the republic at the battle of Philippi, but surrendered to Antony soon afterwards, and was by him appointed to the command of his fleet. He died while governor of Syria under Augustus.

BICHAT, MARIE-FRANÇOIS XAVIER, a celebrated French anatomist and physiologist, was born at Thoirette in the department of Ain, in 1771 His father, who was himself a physician, was his first instructor. He entered the College of Nantua, and afterwards studied at Lyons. In mathematics and the physical sciences he made rapid progress. Becoming passionately fond of natural history he ultimately devoted himself to the study of anatomy and surgery, under the guidance of Petit, chief surgeon to the Hôtel Dieu at Lyons. He resumed for a time his early studies, restricting himself, however, within such limits as did not interfere with his medical pursuits. Petit soon discerned the superior talents of his pupil, and, although the latter had scarcely attained the age of twenty, employed him constantly as his assistant. The revolutionary disturbances compelled Bichat to fly from Lyons and take refuge in Paris about the end of the year 1793. He there became a pupil of the celebrated surgeon Desault. One day, volunteering to supply the place of an absent pupil who was to have recapitulated the lecture of the day before, he acquitted himself so admirably that Desault was strongly impressed with his genius; and from that time Bichat became an inmate in his house, and was treated as his adopted son. For two years he actively participated in all the labours of Desault, prosecuting at the same time his own researches in anatomy and physiology. The sudden death of Desault in 1795 was a severe blow to Bichat. His first care was to acquit himself of the obligations he owed his benefactor, by contributing to the support of his widow and her son, and by conducting to a close the fourth volume of Desault's *Journal de Chirurgie*, to which he added a biographical memoir of its author. His next object was to reunite and digest in one body the surgical doctrines which Desault had published in various periodical works. Of these he composed, in 1797, the book entitled *Œuvres Chirurgicales de Desault, ou Tableau de sa Doctrine, et de sa Pratique dans le Traitement des Maladies Externes*, a work in which, although he professes only to set forth the ideas of another, he develops them with the clearness and copiousness of one who is a master of the subject. He was now at liberty to pursue the full bent of his genius, and, undisturbed by the storms which agitated the political world, he directed his full attention to surgery, which it was then his design to practise. We meet with many proofs of his industry at this period in the *Recueil de la Société Médicale d'Emulation*, an association of which Bichat was one of the most active members. In 1797 he began a course of anatomical demonstrations, and his success encouraged him to extend the plan of his lectures, and boldly to announce a course of operative surgery. Bichat's reputation was now fully established, and he was ever after the favourite teacher with the Paris students. In the following year, 1798, he gave, in addition to his course on anatomy and operative surgery, a separate course of physiology. A dangerous attack of hæmoptysis interrupted for a time these heavy labours; but the danger was no sooner past than he plunged into new engagements with the same ardour as before. He had now scope in his physiological lectures for a fuller exposition of his original views on the animal economy, which excited much attention in the medical schools at Paris. Sketches of these doctrines were given by him in three papers contained in the Memoirs of the *Société Médicale d'Emulation*. The doctrines were afterwards more fully developed in his *Traité sur les Membranes*, which appeared in 1800. In the notes to a small work, in which he gave in a condensed form the lessons of Desault on the diseases of the urinary passages, are found the germs of many of Bichat's peculiar views.

His next publication was the *Recherches Physiologiques sur la Vie et sur la Mort* (1800), which consists of two dissertations. In the first he explains his classification of functions, and traces the distinction between the animal and organic functions in all its bearings. In the second he investigates the connection between life and the actions of the three central organs, the heart, lungs, and brain. But the work which contains the fruits of his most profound and original researches is the *Anatomie Générale*, published in 4 vols. 8vo in 1801.

Before Bichat had attained the age of eight-and-twenty he was appointed physician to the Hôtel Dieu, a situation which opened an immense field to his ardent spirit of inquiry. In the investigation of diseases he pursued the same method of observation and experiment which had characterized his researches in physiology. He learned their history by studying them at the bedside of his patients, and by accurate dissection of their bodies after death. He engaged in a series of examinations, with a view to ascertain the changes induced in the various organs by disease, and in less than six months he had opened above six hundred bodies. He was anxious also to determine, with more precision than had been attempted before, the effects of remedial agents, and instituted with this view a series of direct experiments on a very extensive scale. In this way he procured a vast store of valuable materials for his course of lectures on the Materia Medica, the completion of which was prevented by his death; but a great part of the facts were embodied in the inaugural dissertations of his pupils. Latterly, he also occupied himself with forming a new classification of diseases.

Bichat commenced a new work on anatomy, in which

the organs were arranged according to his peculiar classification of their functions, under the title of *Anatomie Descriptive*, but he lived only to publish the first two volumes. It was continued on the same plan, and completed in five volumes by his assistants MM. Buisson and Roux. His death was occasioned by a fall from a staircase at the Hôtel Dieu, which threw him into a fever. Exhausted by excessive labour, and enfeebled by constantly breathing the tainted air of the dissecting-room, he sank under the attack and died on the 22d July 1802, attended to the last by the widow of his benefactor, from whom he had never been separated. His funeral was attended by above six hundred of his pupils, and by a large number of the physicians of Paris. His bust, together with that of Desault, was placed in the Hôtel Dieu by order of Napoleon.

BICYCLE. As the derivation of the term implies, the chief component parts of this machine consist of two wheels. The word is applied to those two-wheeled machines which have been brought to their present state of perfection for human locomotion during the past five years. Shortly after the close of the great Continental war in 1815, the first bicycle was introduced into England from France. It was at the best an awkward affair, composed of a couple of heavy wooden wheels of equal diameter, one behind the other, and joined together by a longitudinal wooden bar on which the rider's seat was fixed, the mode of propulsion being the pushing the feet against the ground. That such a cumbersome method of locomotion soon died a natural death is not to be wondered at. For the next fifty years no real progress was made, as various kinds of levers and other attempted appliances were found too intricate. In 1869 M. Michaux of Paris conceived the idea of making the front or driving wheel much larger than the hind wheel; and very soon afterwards, M. Magee, another Parisian, still further improved bicycles by making them entirely of steel and iron. The principle of crank action attached to revolving axles having also become developed, the pastime of bicycling was entirely revolutionised. India-rubber tyres and strong breaks were brought into requisition to relieve jolting; and now-a-days a crack racing bicycle with a driving-wheel from 55 to 60 inches diameter does not exceed 50 lb in weight, or about half the weight of one of the old wooden machines. Tricycles have been tried, but no great amount of speed will ever be got out of them until the friction and weight can be materially reduced.

The diameter of the front or driving wheel of the modern bicycle varies from $2\frac{1}{2}$ to 5 feet, according to the length of the rider's legs. When it is meant for racing, most of the component parts are lighter, and the rest for relieving the legs when going down hill is dispensed with. The rider sits astride a small saddle, and the motive power is obtained from the feet working the crank treadles attached to the revolving axle of the driving-wheel. There being no lateral support to the machine, the first thing to be learnt is balancing, after which it is best to begin riding down a gentle gradient without using the treadles. Steering, which is managed by a transverse handle attached to the driving-wheel and placed in front of the rider, should be mastered in the same manner, after which the feet and legs may be brought into play on the treadles and speed gradually acquired. Falls are inevitable at first, and they are best avoided by slightly turning the driving-wheel in the direction the machine is inclining, not the contrary way. Care must be taken to keep all bearings, &c., oiled from time to time, in order to prevent friction and so lessen speed. With the exception of skating, bicycling is the quickest means of locomotion that man possesses. A fair bicyclist can outstrip a horse in a day, whilst an expert can do so in an hour. Bicycling has rapidly grown in favour during the past two years; and long tours are now made with the greatest ease. Where the roads are fairly level, and in a tolerably good state of repair, the bicycle is unsurpassed as a means of self-locomotion. In hilly and mountainous countries, where there are no made roads, or where they are much broken up and heavy, it is next to useless, although india-rubber tyres to a certain extent relieve the jolting over rough ground. Lightness, great strength, and the best of workmanship are necessary in the manufacture of bicycles in order to prevent serious accidents. It is in the two former requisites that steel and india-rubber have such an advantage over iron and wood.

As a proof of the perfection to which bicycle-riding has now been brought, the following best performances on record, over a prepared cinder path, may be mentioned, viz. :—

Miles.	Hours.	Min.	Sec.	Miles.	Hours.	Min.	Sec.
$\frac{1}{2}$	0	1	$32\frac{1}{5}$	10	0	34	41
$\frac{3}{4}$	0	2	$19\frac{3}{5}$	20	1	12	38
1	0	3	0	30	1	52	48
2	0	6	31	40	2	31	48
3	0	9	58	50	3	9	21
4	0	13	$19\frac{3}{5}$	60	4	11	24
5	0	16	41	70	4	56	35
6	0	20	55	80	5	46	48
7	0	24	23	90	6	42	21
8	0	28	5	100	7	33	43
9	0	31	2	106	7	58	$54\frac{1}{2}$

The last of these, as one of the London daily journals remarked, fairly ranks as "the most extraordinary performance on record of any man, animal, or machine." The distance from Tunbridge to Liverpool, 234 miles, has been accomplished in 18 hours 35 minutes. A hundred miles a day, over fair roads, has often been achieved for several days together, and many such journeys are recorded. A ride of 800 miles, from London to John O'Groats, was made in 14 days, over unexceptionally hilly and heavy roads, in June 1873.

BIDA, an inland town of Africa, situated in about N. lat. 9° 5′ and E. long. 6° 5′, sixteen miles N. of the River Niger or Quorra, and lying N.N.W. of the town of Egga. Bida, which was visited by Dr Baikie in 1862, is a large town, the capital of the kingdom of Nupe.

BIDDLE, JOHN, frequently called the father of English Unitarianism, was born in 1615 at Wotton-under-Edge in Gloucestershire. He was educated at the grammar school of his native town, and then proceeded to Magdalen Hall, Oxford. He graduated as bachelor of arts in 1638 and as master in 1641, and was then appointed to the mastership of the free school in the city of Gloucester. While conducting this school in an admirable manner he diligently prosecuted his theological studies; and the results he arrived at were of such a nature as to draw down upon him the reprobation of the civic authorities. He circulated privately a tract called *Twelve Arguments drawn out of Scripture, wherein the commonly-received opinion touching the deity of the Holy Spirit is clearly and fully refuted*; and towards the close of 1645 he was summoned before the Parliamentary committee then sitting at Gloucester. By them he was committed to prison, though he was at the time labouring under a dangerous fever. He was released on bail after an imprisonment of some duration, and was then called before the Parliament, which desired to inquire into his views. After tedious proceedings Biddle was committed to custody, in which he remained for five years. During that time the Assembly of Divines at Westminster had discussed his opinions, and in defence he published his *Twelve Arguments*. The book was at once ordered by Parliament to be seized and burned by the hangman. Notwithstanding this, Biddle issued two tracts, one a *Confession of Faith with regard to the Holy Trinity*, the other *Testimonies of Irenæus, &c., concerning the one God and the Persons of the Holy Trinity*. These were suppressed by Government, and the Assembly of Divines eagerly pressed for the passing of an Act by which heretics like Biddle could be put to death. This, however, was resisted by the army, and by many of the Independent Parliamentarians; and after the death of the king, Biddle

was allowed to reside in Staffordshire under surveillance. In 1651 the general Act of Oblivion gave him complete freedom, and his adherents soon began the practice of meeting regularly for worship on Sundays. They were called Biddellians, or Socinians, or Unitarians, the name which has now become associated with their opinions. Biddle was not left long in peace. He translated some Socinian books, among others the *Life of Socinus*, and published two catechisms, which excited a fury of indignation against him. He was summoned before the Parliament and imprisoned. The dissolution of that body again set him at liberty for a short time, but he was presently brought up for some expressions used by him in a discussion with a Baptist clergyman. He was put upon trial, and was only rescued by Cromwell, who sent him out of the way to one of the Scilly Islands, and after three years released him. But in 1662 he was again arrested, and fined £100. As he was unable to pay this sum, he was at once committed to prison, where fever, caused by the pestilential atmosphere, carried him off on the 22d September 1662.

BIDEFORD, a municipal borough, market-town, and seaport, in the county of Devon, eight miles S.W. of Barnstaple, with which it is connected by railway. It is situated on the slopes of two hills which rise from the banks of the River Torridge, near its confluence with the Taw, about four miles from the sea. The two portions of the town are united by a bridge of fourteen arches, built, it is said, in the 14th century, and widened in 1864. The bridge forms a favourite promenade, and is endowed for its repair with lands that produce an annual rent of £300 or £400. Many of the houses in the town are built in the ancient fashion with bricks and wooden framework. The old church of St Mary, with the exception of the tower, was taken down and rebuilt in 1864, and the town-hall is also of modern erection. In addition to these buildings Bideford possesses several large churches and schools, a union workhouse, assembly-rooms, a hospital for aged poor, a reading-room, and a literary and scientific institution. Bideford was already a place of some size under the Saxons, received the right of holding a market in 1271, and was made a free borough in 1573. In the 16th and 17th centuries it was a place of great trade, and in some respects was only exceeded by Exeter and London. The weaving of silk was introduced in 1650, and after the revocation of the Edict of Nantes received extensive development from some French refugees. Bideford now manufactures earthen wares, ropes, sails, and leather, builds ships, and has a considerable trade both domestic and foreign. Vessels of 500 tons can come up to its quay. It exports oak-bark, grain, and its own manufactures, and imports timber from Canada and the Baltic, with fruits, wines, and brandies from the south of Europe. The value of its imports was, in 1873, £13,310. Anthracite, coarse potters' clay, and a mineral paint are found in the neighbourhood. Population of municipal borough in 1871, 6969.

BIDPAI, more commonly known under the corrupted name of Pilpay, is the supposed author of a famous collection of Hindu fables. Nothing is known of Bidpai beyond the name, which, indeed, occurs only in the Arabic version, but the history of the collection of stories is curious and interesting. The origin of them is undoubtedly to be found in the *Pantcha Tantra*, or Five Sections, an extensive body of fables or apologues. A second collection, called the *Hitopadesa*, has become more widely known in Europe than the first, on which it is apparently founded. In the 6th century A.D., a translation into Pehlvi of a number of these old fables was made by Barzuyeh, a physician at the court of Nushirvan, king of Persia. No traces of this Persian translation can now be found, but nearly two centuries later, Abdallah-ibn-Mokaffah translated the Persian into Arabic; and his version, which is known as the "Book of Kalilah and Dimna," from the two jackals in the first story, became the channel through which a knowledge of the fables was transmitted to Europe. It was translated into Greek by Simeon Sethus towards the close of the 11th century; his version, however, does not appear to have been retranslated into any other European language. But the Hebrew version of Rabbi Joel, made somewhat later, was translated into Latin by John of Capua, and in that form became widely known. Since then the fables have been translated into nearly every European tongue. There are also versions of them in the modern Persian, Malay, Mongol, and Afghan languages.

See Wilson's analysis of the Pantcha Tantra, in the *Mem. of the Royal Asiat. Soc.*, i.; De Sacy's introduction to his edition of the *Kalilah and Dimna*, 1816; articles by the same in *Notices et Extr. des MSS. de la Bib. du Roi*, vols. ix. and x.; Wolff, *Bidpai's Fabeln*, 2 vols. 1837; Loiseleur des Longchamps, *Essai sur les Fables Indiennes*, 1838; Benfey, *Pantcha Tantra*, 2 vols. 1859.

BIEL (or in French BIENNE), a town of the canton of Bern, in Switzerland, situated at the foot of the Jura Mountains, near the northern end of the lake to which it gives its name. It is well built, and possesses a town-house of some antiquity, a remarkable church, a hospital, a gymnasium, and an industrial school. There is considerable industrial activity in Biel, especially in the manufacture of cotton, leather, iron wire, and watches. Founded in the 11th or 12th century, Biel continued under the authority of the bishopric of Basel till the beginning of the 15th, when it formed an alliance with Bern, Soleure, and Freiburg. Its defence against the French in 1798 is commemorated by an obelisk on a neighbouring eminence. Its incorporation with Basel dates from 1815. Population, 8113.

BIEL, GABRIEL, frequently but erroneously styled the last of the scholastics, was born at Spire about the middle of the 15th century. He held for some time a pastoral charge at Mainz, and afterwards removed to Urach. On the foundation of the University of Tübingen in 1477 he was appointed to the professorship of theology, and was twice afterwards promoted to the dignity of rector. Some years before his death, in 1495, he entered a religious fraternity. Biel was a follower of William of Occam, and professes only to develop systematically the principles of his master. His great work, *Collectorium super Libros Sententiarum G. Occami* (1508, 1512, and various dates), is an admirably clear and consistent account of the nominalist doctrine, and presents the complete system of scholastic thought regarded from that point of view. The strong empirical individualism of the work, tending necessarily to limit the province of reason and extend that of faith, together with scattered utterances on special points, which gained for Biel the title of *Papista Antipapista*, had considerable influence in giving form to the new doctrines of Luther and Melanchthon. From its lucidity and relative completeness Biel's work is the best specimen of the final aspect of scholasticism. His other works have also been frequently reprinted. With regard to the title *Ultimus Scholasticorum*, often bestowed on Biel, it has been pointed out by all the best authorities that such a designation is quite inappropriate; scholasticism did not cease even in Germany with Biel, and it continued to flourish long after his time in the universities of Spain. (Stöckl, *Phil. d. Mittelalt.*, ii. § 269; Roscher, *Ges. d. Nationalökonomik*, pp. 21-28.)

BIELAU, frequently distinguished as Langen Bielau, the longest village in the Prussian monarchy. It is situated in the government of Breslau in Silesia, on a tributary of the Piela, and extends for a distance of rather more than four miles. Its industrial establishments are numerous

and important, the cotton manufactory alone employing 2000 looms; while bleaching, dyeing, printing, tile-making, and sugar-refining are all extensively carried on. There is an old castle in the village belonging to Count Sandreczky. Population in 1871, 13,070.

BIELAYA TSERKOV (*i.e.*, White Church), a township of Russia, in the government of Kieff, 32 miles S.S.W. of Vasilko, on the main road from Kieff to the Crimea, in 49° 47′ N. lat. and 30° 7′ E. long. First mentioned in 1155, Bielaya Tserkov was destroyed during the Mongolian invasion, but afterwards recovered its prosperity. In 1550 a castle was built in the town by Prince Prunsky, waiwode of Kieff, and various immunities were bestowed on the inhabitants. A Polish army occupied the place in 1651, and from that time it was alternately subject to Poland and to independent hetmans. In 1774 it received a charter from Stanislas Augustus, and in 1793 was united to Russia. The principal buildings of Bielaya Tserkov include two Greek churches, one Roman Catholic church, two synagogues, a hospital, and a gymnasium (founded in 1846). In commercial activity the town only yields to Kieff, Berdicheff, and Uman—the chief articles of trade being cattle and grain. There are eleven annual fairs, three of which last for ten days each. The sales at these fairs amount to upwards of £28,000. Population in 1860, 12,075, of whom 7349 are Jews.

BIELEFELD, a town in the Prussian province of Westphalia, the capital of a circle in the government of Minden. It is situated at the foot of the Osning, and consists of two portions, separated by the River Lutter, which were first united into one town in 1520. Among its public buildings and institutions are the old town church, with a curious carved altar piece, the town-house, the gymnasium, and the provincial industrial school. On the height above the town is the old castle of Sparrenberg, for a long time employed as a prison. It was founded about the 12th century, and originally bore the name of Lowenberg. Bielefeld is the centre of the Westphalian linen trade, and contains extensive factories and bleachfields. The Ravensberg factory has upwards of 24,000 spindles, and the Vorwärts, 10,700. Tobacco, glass, cement, cast-iron, leather, tiles, &c., are also manufactured in the town. Bielefeld is mentioned as early as the 9th century, as *Belanvelde*, and rose into importance in the 11th or 12th as the capital of the countship of Ravensburg. It joined the Hanseatic league in 1270, and about the same time began to engage in the linen manufacture, which was greatly extended during the 16th and 17th centuries by a number of refugees from the Netherlands. In 1666 the town passed with the countship to the duchy of Brandenburg. Population in 1871, 21,834.

BIELEFF, a town of Russia, in the government of Tula, and 82 miles from that city, on the left bank of the Oka, in 53° 48′ N. lat. and 35° 9′ E. long. It is first mentioned in 1147; it belonged to Lithuania in the end of the 14th century; and in 1468 it was raised to the rank of a principality, dependent on that country, by Basil Romanovitch, who had come thither from Odoeff. In the end of the 15th century this principality began to separate from Lithuania and attach itself to the Grand Duchy of Moscow; and by the peaceful treaty of Ivan III. with Alexander the Lithuanian Bieleff was ultimately united to Russia. In the 16th century it suffered greatly from the Tatars, especially in the years 1507, 1512, 1530, 1536, and 1544. In 1538 Ivan the Terrible exiled Prince John of Bieleff to Vologda, and in 1565 declared the lordship his own property. In 1607 Nikiyitch Romanoff, general of the Emperor Basil Ivanovitch, gained a complete victory in the neighbourhood against the rebellious Prince Mosalsky. Transferred in 1708 from the Smolensk to the Kievan government, Bieleff passed in 1719 to the Bielgorod district of Orloff, and in 1777 was made a departmental town of the government of Tula. In 1826 the Empress Elizabeth Alexievna died in Bieleff on her way from Taganrog to St Petersburg. The buildings of the town include nineteen churches and two monasteries, a hospital, a widow's asylum, a foundling institution, an almshouse, a prison, and a theatre. A public library was founded in 1858 in memory of Basil Zhukovsky, who was born in a neighbouring village. The industrial establishments comprise tallow-boiling premises, oil manufactories, a tannery, a sugar-refinery, a distillery, &c. In extent of trade Bieleff ranks next in the government to Tula—the most important articles being grain, hemp, oil, and tallow. A great fair is held from the 28th of August to the 10th of September. The population in 1860 was 8063, by far the greater proportion belonging to the Greek Church.

BIELGOROD (*i.e.*, White Town), a town of Russia, in the government of Kursk, 87 miles S.S.W. from that city, in 50° 36′ N. lat. and 36° 37′ E. long., on the right bank of the North Donetz, near the confluence of the Vizelka. It occupies a high chalk hill, from which are annually quarried about 112 tons. The date of the founding of Bielgorod is uncertain, because it has been confounded with two other places of the same name. In Karamsin's *History* it is mentioned that the Grand Duke Theodore Ivanovitch in 1593 sent to found Bielgorod on the ruins of Siever; and it is certain that ancient remains are still to be seen in this city. In the 17th century Bielgorod suffered ceaselessly from Tatar incursions, against which, by command of the Emperor Michael Theodorovitch, there was built (from 1633 to 1740) an earthen wall, with twelve forts, extending upwards of 200 miles from the Vorskla to the Don. These defences were called the Bielgorod line, along which, in the reign of Alexias Michaelovitch, there were settled emigrants from Cherkas, Zimbar, Corsun, and elsewhere. In 1666 an episcopal see was established in the town, and the archbishops lived there till 1833, when they were transferred to Kursk. In 1779 Bielgorod was made the chief town of a circle in the Kursk government. There are two cathedral churches in the place, Trinity and Assumption, both built in the 16th century, as well as fifteen other churches, two monasteries, a theological seminary, an almshouse, and a hospital. In 1862 a bank was established with a capital of between £10,000 and £15,000. Only a few of the houses are built of stone. Wax-candles, tallow-candles, leather, soap, and bricks are manufactured, and a considerable trade is carried on in grain and cattle. There are three annual fairs on the 10th Friday after Easter, the 29th June, and 15th August respectively. Population in 1860, 11,722, almost all belonging to the Greek Church.

BIELITZ, a town of Austrian Silesia, in the circle of Teschen, on the Biala River, a sub-tributary of the Vistula, and opposite the Galician town of Biala, with which it is connected by a bridge. It is the seat of the superintendent of all the Protestants in Moravia, and the residence of the Sulkowsky family, in favour of whom the lordship of Bielitz was raised to a duchy in 1754. The castle is a fine building of some antiquity, surrounded by a beautiful park. The principal industries of the town are the spinning of flax and the printing and dyeing of cloth, the last especially being carried on with great success. A valuable traffic is maintained not only in the produce of the factories but also in Hungarian wine and Galician salt. The town was founded in the 13th century, and in the 15th and 16th was a fortified place. It is connected by means of a branch line with the Kaiser-Ferdinand Northern Railway. Population in 1869, 10,721.

BIELLA, a town of Italy, in the province of Novara, 38 miles N.E. of Turin, with which it is connected by rail. It is built partly on the slope of a hill and partly on the

banks of two small streams called the Cervo and Aurena,—the palatial old houses of the upper portion being now inhabited by the poorer classes. Several of the streets have arcades along the sides. It is the seat of a bishop, and has a cathedral, an episcopal palace, and a theological seminary. The principal industries are the manufacture of cloth and paper, and the trade consists mainly in oil, chestnuts, and silk. Population in 1870, 11,935.

BIELOPOLI, a town of Russia in the government of Kharkoff, near the Vuira and Kriuga, 37 miles N.W. from the town of Sum, in 51° 9′ N. lat., and 34° 19′ E. long. It was founded in 1672. A very extensive trade in wheat, salted fish, salt, pitch, and timber is carried on by the inhabitants, who number upwards of 12,000.

BIELOSTOK (in Polish BIALYSTOK), a town of Russia, in the government of Grodno, in 53° 8′ N. lat. and 23° 9′ E. long., 50 miles S.W. of Grodno on the River Biela, a tributary of the Suprasla. Founded in the 14th century it was long an important proprietary village belonging to the Veselovskis. In the 17th century it passed to the Branetskis, at whose solicitation Augustus III., in 1749, raised it to the rank of a borough and gave it civic rights. This increased its prosperity, and after the third partition of Poland in 1793, the Prussian Government, to whom it had been assigned, made it the seat of an administrative department. By the peace of Tilsit in 1807, Bielostok was given to Russia along with the department of the same name, which in 1808 was divided into the four districts of Bielostok, Bielsk, Sokol, and Drogotchin. The public buildings of Bielostok comprise a Greek and a Roman Catholic church, several synagogues, a hospital, a castle (used as a prison), a gymnasium, an institution for the daughters of the nobility, and various other schools. There are three cloth factories and an extensive brewery; cotton and wool-spinning are both carried on, and leather, oil, soap, and tallow are manufactured. There is also an important trade in grain, wood, and various industrial articles. In 1860 the population was 16,544, no fewer than 11,288 being Jews.

BIENHOA, the capital of one of the six provinces of Lower Cochin-China, situated about 20 miles to the north-west of Saigon, on a canal that connects it with that city. It was captured by the French admiral Bonard in 1861, and is now one of the fortified posts in the French possessions. Sugar-mills were started in 1869 by an English company; but, owing to the jealousy of the Anamites, they had soon to be closed. The population of the "Inspection" of Bienhoa is 19,260.

BIEZHETZ, a town of Russia, in the government of Tver, and 181 miles from that city, situated on the right bank of the Mologa, in 57° 46′ N. lat. and 36° 43′ E. long. On the left bank of the river lies the suburban village of Shtap, chiefly inhabited by the lower orders. Biezhetz is mentioned in the chronicles of 1137. On the fall of Novgorod, to which it had belonged, it was incorporated with the grand-duchy of Moscow; and in 1771 it was added to the government of Tver. Candles, leather, brandy, beer, flour, malt, oil, and bricks are all manufactured; but a more important branch of industry is the making of bags for grain and flour. There are two weekly markets and two annual fairs. Population in 1860, 5423.

BIGAMY, according to the statute now in force (24 and 25 Vict. c. 100, § 57), is the offence committed by a person who "being married shall marry any other person during the life of the former husband or wife." In the canon law the word had a rather wider meaning, and the marriage of a widow came within its scope. At the Council of Lyons (1274 A.D.) bigamists were stripped of their privilege of clergy. This canon was adopted and explained by the English statute 4 Edward I. st. 3, c. 5; and bigamy, therefore, became a usual counterplea to the claim of *benefit of clergy*. However, by 1 Edward VI. c. 12, § 16, every person entitled to the benefit of clergy is to be allowed the same, "although he hath been divers times married to any single woman or single women, or to any widow or widows, or to two wives or more." A bigamous marriage, by the ecclesiastical law of England, is simply void. By the statute 1 James I. c. 11, confirmed by later statutes, the offence was made a felony. It is immaterial whether the second marriage has taken place within England and Ireland or elsewhere, and the offence may be dealt with in any county or place where the defendant shall be apprehended or be in custody. The following clause embodies the necessary exceptions to the very general language used in the definition of the offence:—"Provided that nothing in this section contained shall extend to any second marriage contracted elsewhere than in England and Ireland by any other than a subject of Her Majesty, or to any person marrying a second time whose husband or wife shall have been continuously absent from such person for the space of seven years then last past, and shall not have been known by such person to be living within that time, or shall extend to any person who at the time of such second marriage shall have been divorced from the bond of the first marriage, or to any person whose former marriage shall have been declared void by any court of competent jurisdiction." The punishment is penal servitude for not more than seven nor less than five years, or imprisonment with or without hard labour, not exceeding two years. A valid marriage must be proved in the first instance in order to support a charge of bigamy. A *voidable* marriage, such as were marriages between persons within the prohibited degrees before 5 and 6 Will. IV. c. 54, will be sufficient, but a marriage which is absolutely *void*, as all such marriages now are, will not. For example, if a woman marry B during the lifetime of her husband A, and after A's death marry C during the lifetime of B, her marriage with C is not bigamous, because her marriage with B was a nullity. In regard to the second marriage (which constitutes the offence) the English courts have held that it is immaterial whether, but for the bigamy, it would have been a valid marriage or not. An uncle, for example, cannot marry his niece; but if being already married he goes through the ceremony of marriage with her he is guilty of bigamy. In an Irish case, however, it has been held that to constitute the offence the second marriage must be one which, but for the existence of the former marriage, would have been valid. With reference to the case in which the parties to the first marriage have been divorced, it may be observed that no sentence or act of any foreign country can dissolve an English marriage *a vinculo* for grounds on which it is not liable to be dissolved *a vinculo* in England (R. *v.* Lolley, in Russell and Ryan's *Criminal Cases*, 237). Hence, a divorce *a vinculo* for adultery, in a Scotch court, of persons married in England is not within the statute.

In Scotland, at the date of the only statute respecting bigamy, that of 1551, cap. 19, the offence seems to have been chiefly considered in a religious point of view, as a sort of perjury, or violation of the solemn vow or oath which was then used in contracting marriage; and, accordingly, it was ordained to be punished with the proper pains of perjury. But this injunction has not in every instance been complied with; and, from considerations of policy or expediency, the court has long been in the habit of inflicting an arbitrary punishment, suited, as nearly as may be, to the degree of guilt brought home to the prisoner. Neither marriage need be regular, but it is not yet settled whether a marriage constituted by habit and repute, or by promise *subsequente copula*, can be relevantly libelled in a

charge of bigamy. The parties to the first marriage must, of course, have been lawfully entitled to marry. It is a good defence that the accused was divorced from his first wife before contracting the second marriage, even though the decree should afterwards have been set aside, unless it has been obtained corruptly and set aside for that reason. It is also a good defence that, at the time of contracting the second marriage, the accused had reasonable grounds for believing the other spouse to be dead. To constitute the crime of bigamy, it is not necessary that the second marriage should be such that, but for the first marriage, it would have been legal. The punishment is imprisonment, and occasionally penal servitude.

BIGNON, Jerome, a French lawyer, was born at Paris in 1589. He was uncommonly precocious, and under his father's tuition had acquired an immense mass of knowledge before he was ten years of age. In 1600 was published a work by him entitled *Chorographie, ou Description de la Terre Sainte*. The great reputation gained by this book introduced the author to Henry IV., who placed him for some time as a companion to the duke of Vendôme, and afterwards made him tutor to the Dauphin. In 1604 he wrote his *Discourse on the City of Rome*, and in the following year his *Summary Treatise on the Election of the Pope*. He then devoted himself to the study of law, wrote in 1610 a treatise on the precedency of the kings of France, which gave great satisfaction to Henry IV., and in 1613 edited, with learned notes, the *Formulæ* of the jurist Marculfe. In 1620 he was made advocate-general to the grand council, and shortly afterwards a councillor of state, and in 1626 he became advocate-general to the parliament of Paris. In 1641 he resigned his official dignity, and in 1642 was appointed by Richelieu to the charge of the royal library. He died in 1656.

BIGORDI, Domenico. See Ghirlandaio.

BIJAINAGAR, or Bijanagar, an ancient city in the south of India, once the capital of a great Hindu empire, but now in ruins, situated on the south bank of the Tumbhadrá River, directly opposite to Annagundi, in 15° 19′ N. lat. and 76° 32′ E. long. The city has been enclosed with strong stone walls on the east side, and is bounded by the river on the west, the circumference of the whole appearing to be about eight miles. The streets of this city, from 30 to 40 yards wide, can be traced between the immense piles of rocks crowned with pagodas; and one street yet remains perfect. The building of this metropolis was begun in 1336. Between the kings of the principality, of which it was the capital, and the Mahometan sovereigns of the Deccan constant hostility was maintained. In 1564 Rám Rájá, the king of Bijainagar, was totally overthrown on the plains of Telikotá, by a combination of the four Mahometan sovereigns of the Deccan, who immediately marched to the metropolis, which they abandoned to pillage. From that time it has lain in ruins.

BIJAPUR, or Bijaipur, in Southern India, the ancient capital of an independent sovereignty of the same name, and once an extensive, splendid, and opulent city, but now retaining only the vestiges of its former grandeur. It is situated in a fertile plain, in 16° 50′ N. lat. and 75° 48′ E. long., and is a place of great extent, consisting of three distinct portions—the citadel, the fort, and the remains of the city. The citadel, a mile in circuit, is a place of great strength, well built of the most massive materials, and encompassed by a ditch 100 yards wide, formerly supplied with water, but now nearly filled up with rubbish, so that its original depth cannot be discovered. It was built in 1489, by Yusaf Adil Sháh, the founder of the dynasty of Bijápur. The fort consists of a rampart flanked by numerous towers, a ditch, and a covered way. Its defences, which are not less than six miles in circumference, were completed by Ali Adil Sháh in 1566. The interior formerly contained the king's palace, the houses of the nobility, large magazines, and extensive gardens. At present, though considerable portions of the area are covered with buildings or ruins, there is room for corn-fields and extensive enclosures. Outside the fort are remains of a vast city, now for the most part in ruins, but the innumerable tombs, mosques, caravanserais, and other edifices, which have resisted the havoc of time, afford abundant evidence of the ancient splendour of the place. It is asserted by the natives that Bijápur contained, according to authentic records, 1600 mosques and nearly 1,000,000 houses. The number of houses is certainly overrated; that of the mosques, in the opinion of recent travellers, is no exaggeration. The outer wall of the city on the western side runs nearly south and north, and is of great extent. It is built of stone, is of prodigious thickness, and is about 20 feet in height, with a ditch and rampart; and at intervals of 100 yards are capacious towers, built of large hewn stones. The whole is now in a ruinous condition,—the wall and the towers having in many places fallen into the ditch, and in other parts being covered with rubbish. Several mosques and mausoleums, adorned with all the embellishments of Eastern architecture, are still to be seen in Bijápur. The fort in the interior is adorned with many of these edifices, in rather better preservation than the outworks. Among these is the great mosque, which is 97 yards long by 55 broad. The wings, which are 15 yards broad, project 73 yards from the north and south ends, enclosing on three sides, with the body of the mosque, a large reservoir of water and a fountain. The mausoleum of Sultan Muhammad Sháh is a plain building, 153 feet square, over which is reared a dome 117 feet in diameter at its greatest concavity, and called by the natives the grand cupola. The mosque and mausoleum of Ibrahim Adil Sháh, king of Bijápur, which was probably completed about the year 1620, is said to have cost £1,700,000, and to have occupied thirty-six years in its construction. It is built on a basement 130 yards in length by 52 in breadth, and raised 15 feet. On this is a plain building, 115 feet by 76, covered by an immense dome raised on arches. The mausoleum is a room 57 feet square, enclosed by two verandahs, 13 feet in breadth and 22 feet in height. There are, besides, many other public buildings more or less injured by time and the violence of the Marhattás. Almost all the buildings, the palaces of the fort excepted, are of massive stone, and in the most durable style; and at the same time the workmanship is minutely elegant. Among the curiosities of the capital is the celebrated monster gun, stated to be the largest piece of cast brass ordnance in the world. It was captured from the king of Ahmadnagar by the king of Bijápur about the middle of the 17th century. An inscription on the gun recording that fact was erazed by Aurangzeb, who substituted the present inscription, stating that he conquered Bijápur in 1685. The city is well watered, having, besides numerous wells, several rivulets running through it.

After the dissolution of the great Báhmani dynasty of the Deccan in 1489, a race of independent sovereigns arose, who ruled over the new kingdom of Bijápur, extending on the east from the confluence of the Bhímá and the Krishná to the sea-coast, on the west from Goa to Bombay. Their rule endured through several generations, until at length, in 1650, Sháh Jahán compelled them to become tributary to the empire; and shortly after, their monarchy was totally subverted by his successor Aurangzeb. The city and territory of Bijápur remained annexed to Dehli till 1724, when the Nizám established his independence in the Deccan, and included Bijápur within his dominions. His sway over this portion of his acquisitions, was, however, of brief duration; for, being defeated by the Peshwá

in 1760, he was constrained to purchase peace by its cession to the Marhattás. Upon the fall of the Peshwá in 1818, Bijápur passed into the hands of the British, and was by them included in the territory assigned to the Rájá of Satárá.

The place, as already intimated, is rich in monuments of the bygone period when Bijápur was the capital of a powerful and flourishing Mahometan kingdom. Such traces of the past it is always desirable to preserve to the greatest possible extent, as they furnish the best commentary upon the history of the times in which they were raised, and, indeed, constitute their history, so far as manners are concerned. It is fortunate that their value was duly appreciated by the late Rájá of Satárá, who took great pains to preserve them; and that the British Government, participating in the same feeling, has, since the country passed into its possession, manifested great zeal in rescuing these magnificent relics from the ravages of time. Bijápur is distant 130 miles S.E. of Satárá, and 245 S.E. of Bombay.

BIJNAUR, a district of British India, under the Lieutenant-Governor of the North-West Provinces, lying between 29° 1′ and 29° 58′ N. lat., and 78° 1′ and 78′ 55′ E. long., is bounded on the N.E. by the British district of Garhwal, on the E. and S.E. by the British district of Morádábád, and on the W. by the British districts of Mirat, Muzaffarnagar, and Saháranpur. The aspect of the country is generally a level plain, but the northern part of it rises towards the Himálayas, the greatest elevation being 1342 feet above the sea-level. The Koh and Rámgangá are the only streams that flow through the district.

Population in 1872, 737,152 souls, inhabiting 158,583 houses, and 2002 villages or townships. Area of the district, 1902 square miles; persons per square mile, 388; per village, 368; and per house, 4·6. The Hindus numbered 493,601, or 67 per cent. of the total population; Mahometans, 243,455, or 33 per cent.; and Christians and others of unspecified religions, 96 souls. Of the area of the district (namely, 1902·94 square miles), 1036·14 square miles are under cultivation; 432·63 square miles cultivable, but not actually under cultivation; and the remainder uncultivable waste. Principal crops:- Sugar-cane, cotton, rice, pulses, oil-seeds, and different kinds of millet. Principal lines of road:-- (1.) Najíbábád to Hardwar and Srínagar; (2.) Mírat to Bijnaur, Kiratpur, and Najíbabad; (3.) Bijnaur to Nagíná and Barápur; (4.) Najíbábad to Nagína, Nehtaur, Chandpur, and Bashta; (5.) Moradábád to Sahora, Nagina, and Najíbábad; and (6.) Núrpur to Dhámpur, Sherkot, and Afzalgash, on to Kalagash. In 1870–71, the total revenue of Bijnaur district amounted to £143,958, of which £127,316, or 88 per cent., was derived from land. For the protection of person and property, a regular police force of 436 strong is maintained, exclusive of the village watch. In 1872–73, Bijnaur district contained 334 schools, attended by 5819 pupils. The following thirteen towns contain a population exceeding 5000 souls:—(1.) Bijnaur, the headquarters town of the district, in 29° 22′ 36″ N. lat. and 70° 10′ 30″ E. long.; population, 12,865; municipal income in 1872, £1010, 16s.; expenditure, £681, 8s.; rate of taxation, 1s. 7⅜d. per head: (2.) Siohará, population, 8340; municipal income, £94, 18s. 4d.; expenditure, £83, 8s. 6d.: (3) Sáhaspur, population, 6309; not a municipal town: (4.) Najíbábád, population, 17,418; municipal revenue, £1581, 4s.; expenditure, £1425, 16s.: (5.) Shírkot, population, 12,586; municipal revenue, £173, 14s. 5d.; expenditure, £130, 17s. 4d.: (6.) Dhámpur, population, 6555; municipal revenue, £521, 16s.; expenditure, £429, 12s.: (7.) Mandáwar, population, 7622; municipal revenue, £86, 19s. 3d.; expenditure, £115, 13s. 8d.: (8.) Afzalgash, population, 8350; municipal revenue, £100, 1s. 1d.; expenditure, £115, 18s. 11d.: (9.) Nahtor, population, 9392; municipal revenue, £147, 8s. 1d.; expenditure, £84, 3s. 7d.: (10.) Jahálú, population, 5979; not a municipal town: (11.) Chandpur, population, 12,033; municipal income, £506, 12s.; expenditure, £378, 2s.: (12.) Nagina, population, 19,696; municipal income, £925, 12s.; expenditure, £779, 16s.: (13.) Kíratpur, population, 9579; municipal income, £117, 14s.; expenditure, £91, 12s.

Until the latter part of the 18th century Bijnaur belonged to the brave Rohilla Afghans, whose subjugation forms so deep a blot on the career of Warren Hastings. In 1774 the mercenary arms of Britain subjected this people to the oppressive rule of the Nawáb of Oudh, who in turn ceded the district to the East India Company in 1802.

BIKÁNIR, a native state of Rájputáná, under the political superintendence of the British Government, lies between 27° 30′ and 29° 55′ N. lat., and 72° 30′ and 75° 40′ E. long. It is bounded on the N. by the Panjáb, on the E. by the British districts of Hariáná and Shekáwati, on the S. by the native state of Jodhpur or Márwár, and on the W. by the native states of Jasalmér and Bháwalpur. Length of the state from E. to W. 200 miles; breadth, 160 miles; area, 17,676 square miles. The natural aspect of the country is one desolate tract, without a single permanently running stream. Its surface is overspread with undulating sand-hills, of from 20 to 100 feet above the average level, and so loose that men and quadrupeds stepping off the beaten track sink as if in snow. Two streams, the Káturí and Gágar attempt to flow through this dismal region, but are lost in its sands. Water is very scarce, and is raised from wells of from 250 to 340 feet in depth. A few shallow salt lakes are filled by rain water, but they dry up on the setting in of hot weather, leaving a thick crust of salt on their beds, which is used for commercial and domestic purposes. The population of the state has been estimated at 539,000, consisting chiefly of Játs, Rájputs (to which race the chief belongs), and other Hindu tribes, inhabiting 1814 villages, which, according to Elphinstone, are composed of "a few round huts of straw, with low walls and conical roofs, like little stacks of corn." *Bajrá* and *moth* (two species of millet) and water melons are almost the only agricultural products. The inhabitants are very poor. They live chiefly by pasturage,—rearing camels, and horses of a fine breed, which fetch good prices. From the wool which their sheep yield they manufacture every article of native dress and good blankets. The other industries are leather work, sugar-refining, goldsmith's work, iron, brass, copper, stone masonry, tanning, weaving, dyeing, and carpentry. In 1870–71 the total revenue amounted to £111,546, and the expenditure to £123,196. The state is in debt, and is said to be badly managed, the present Mahárájá being entirely guided by favourites. The military force of the state amounts to 5000 regulars, horse and foot. Bikánir was invaded by the adventurer George Thomas in 1799, who levied from the Rájá a black mail of £20,000. The Rájá entered into a treaty of dependence with the British Government in 1818. Principal towns—Bikánir, the capital, Churu, Rájgarh, Ratangarh, and Reni. The town of Bikánir is surrounded by a stone wall, 6 feet thick, 15 to 30 feet high, and 3½ miles in circuit, with five gates and three sally-ports. Estimated population, 60,000. The citadel is half a mile north-east of the city, and is surrounded by a rampart with bastions.

BILÁSPUR, a district of British India, in the Central Provinces, forms the northern section of the Chhattisgarh plateau, and is situated between 21° 45′ and 23° 10′ N. lat. and 81° 30′ and 83° 15′ E. long. It is bounded on the N. by the native states of Rewá and Koriá; on the E. by the Udaipur tributary state of Chhotá Nágpur, and the district of Sambalpur; on the S. by the Ráipur district; and on the W. by the hilly tracts of Mandlá and Bálághát. Extreme length of the district north and south, 106 miles; extreme breadth from east to west, 136 miles; area, 7798 square miles. Biláspur district forms the upper half of the basin of the River Mahánadi. It is almost enclosed on the north, west, and east by ranges of hills, while its southern boundary is generally open and accessible, well cultivated, and closely dotted with villages embedded in groups of fruit trees. The principal hills are—(1), the Maikál range, situated in the north-western extremity of the district; (2), a chain of hills forming part of the Vindhyan range, on the north; (3), the Korbá hills, an offshoot of the Vindhyas, on the eastern boundary; and (4), the Sonákhán block of hills, in the vicinity of the Mahánadi

River. The Mahánadi is the principal river of the district, and governs the whole drainage and river system of the surrounding country. It takes its rise in a mountainous region which is described as the wildest of all wild parts of the Central Provinces, crosses the Biláspur boundary near Seorínáráin, and after a course of 25 miles in the south-eastern extremity of the district enters Sambalpur district. Within Biláspur the river is everywhere navigable for six months in the year. Minor rivers—the Sakrí, Hámp, Tesuá, Agar, Maniári, Arpá, Kharod, Lilágar, Jonk, and Barerí. The most important affluents of the Mahánadi are the Seonath and Hasdú. Besides the natural water supply afforded by the rivers, Biláspur abounds in tanks,—these numbering 7018, as shown in the settlement statistics. The census of 1872 disclosed a total population of 715,398, of whom 435,379, or 60·86 per cent., are Hindus; 7024, or ·98 per cent., Mahometans; 6 Buddhists; 37 Christians; and 272,952, or 38·15 per cent., belong to aboriginal tribes, such as Gonds, Kanwars, Bhumias, Binjwars, Dhanwárs, &c. Among the Hindus, the Chámárs and Pankás deserve particular notice. The former, who form the shoemaker and leather-dealing caste of the Hindu community, had always been held in utter contempt by the other Hindu castes. But between 1820 and 1830 a religious movement, having for its object their freedom from the trammels of caste, was inaugurated by a member of the caste, named Ghásí Dás, who preached the unity of God and the equality of men. Ghásí Dás gave himself out as a messenger of God; he prohibited the adoration of idols, and enjoined the worship of the Supreme Being without any visible sign or representation. The followers of the new faith call themselves *Satnámís*, or the worshippers of *Satnám* or God. They do not keep the Hindu festivals, and they defy the contempt of the Bráhmans. Ghásí Dás, the founder of the faith, was their first high priest. He died in 1850; his son succeeded him, but was assassinated (it was said by the Hindus), and the grandson is the present high priest. The Chámárs in Biláspur number 161,388, or 21 per cent. of the total population. The Pankás, who form about a sixth of the population, are all Kabirpanthís, or followers of Kabir, a religious reformer of the 15th century. There is no great difference between the Kabir Pankás and the Satnámís. They both abstain from meat and liquor, marry at the age of puberty, ordinarily celebrate their ceremonies through the agency of the elders of their own caste, and bury their dead. The Pankás worship the Supreme Being under the name of *Kabir*, and the Chámárs under the name of *Satnám*; while each community has a high priest to whom reverence is paid. At present the majority of the Pankás are cultivators, though formerly all were weavers. The Gonds are the most numerous among the aboriginal tribes, the census of 1872 returning them at 107,359, or 15 per cent. of the total district population; but so great an intermixture has taken place between them and the Hindu races that they have lost their language and most of their ethnical characteristics, such as the flat forehead, squat nose, prominent nostril, dark skin, &c., and are scarcely distinguishable from the other classes of the Hindu labouring population. In addition to some of the Hindu deities which they worship, the Gonds have their own gods—Bara Deva and Dúlá Deva. The Kánwárs are the next largest section of the aboriginal population, and number 28,419 souls. The upper class among them claim to be Rájputs, and are divided into numerous septs. Although an aboriginal tribe, the census returns them as a Hindu caste. All the northern landholders of Biláspur belong to this tribe, which consequently occupies an influential position.

Rice, wheat, pulses, oil-seeds, and cotton are the chief agricultural staples. The census of 1872 returns the total area of the district at 7798 square miles, of which 2089 square miles are under cultivation. The following is the approximate acreage under different crops:—Rice, 882,218 acres; wheat, 79,203; other food grains, 225,443; oil-seeds, 56,039; sugar-cane, 6888; cotton, 72,922; opium, 124; tobacco, 2317; and vegetables, 12,329; total, 1,337,488 acres, or 2089·81 square miles. Of the population, 438,880 live by agriculture, while 276,518 are non-agriculturists. The chief wealth of the district consists in its agricultural produce, and it is not inaptly termed "the land of plenty" by the *Banjárás* or traders, who find here an inexhaustible store of surplus produce for export. Scarcity of food is almost unknown. Coal and iron are the minerals of the district; the former is not worked, and the latter but very slightly, the annual out-turn being reported at about 15 tons only. Sandstone, for building purposes, is quarried near Biláspur and Seorínáráin. The forests produce timber, edible and medicinal roots and plants, lac and tasar-silk cocoons. Imports in 1867-68—sugar, £5274; metals and hardware, £10,985; English piece-goods, £11,194; cattle, £9240; miscellaneous, £10,531; total, £47,224. Exports—rice (as ascertained) £8659; wheat, £6803; other edible grains, £150; cotton, £16,407; molasses, £297; oil-seeds, £18; lac, £15,603; miscellaneous, £5609; total, £53,546. Among local industries the most important is the weaving trade. It is estimated that cotton and silk cloths to the value of £95,000 are every year manufactured. The traffic routes of the district are five in number, the three most important of which are rugged and inaccessible, unfit for wheeled carriages, admitting export or import only by means of pack-bullocks during six months of the year. The other two are simply tracks across the hills and through the jungle. The revenue divisions of the district correspond with its physical features; the hilly area, covering about 5000 square miles, is almost entirely held by large landed proprietors called *Zamíndárs*, who have always occupied a somewhat independent position. The open country, with an area of 3000 square miles, is known as the *Khálsá* jurisdiction, or the tract under direct revenue management through Government officers. Pendrá, Mátin, Uprorá, Kendá, Láphá, Chhúrí, Korbá, Chámpá, Saktí, Bhatgaon, Bilaigarh, Katangí, Pandariá, Kawarda, and Madanpur, are the 15 *Zamíndárís* comprising the hilly area, of which Saktí and Kawardá have been acknowledged as feudatories. Bilaspur, Mungelí, and Seorínáráin are the three *parganás* in the *Khalsa* tract. In 1868-69, the revenues of the district were as follows:—Land-tax, £27,195; excise, £892; stamps, £2234; forest, £434; assessed taxes, £1222; total, £31,977. For the protection of person and property, Government maintained in 1868-69 a regular police of 310 officers and men, at a total annual cost of £4363, besides the village watch or rural constabulary. The executive staff of the district consists of the deputy-commissioner, with two assistants and several sub-collectors. Bilaspur contained, in 1868-69, 33 Government and 58 private schools, attended by 3076 pupils. Besides Bilaspur, to be separately noticed below, there are only four towns of any importance in the district:—Ratanpur, the seat of the ancient Rájás, situated at the base of the Kendá, offshoots of the Vindhyan range, highly attractive to antiquarians and archæologists on account of its great antiquity; it is now in a dilapidated and deserted state. Population, 5111. Mungelí, a rising market-town, situated on the banks of the River Agar. Population, 3542. Kawardá, population, 6590. Seorínáráin, on the Mahanadi, a favourite residence of the Ratanpur court in former days, contains a temple of the Hindu god Naráyan, from which it derives its name. Population about 1500. The climate of the district, though relaxing, is not oppressive. Cholera occasionally breaks out in the epidemic form being generally disseminated by the Jagannáth pilgrims from Central India, whose route to Orissa lies through the district. Fever and smallpox also prevail.

The early history of the district is very obscure. From remote ages it was governed by kings of the Haihai dynasty, known as the Chhattisgarh Rájás, on account of thirty-six forts, of which they were the lords. A genealogical list of kings of this dynasty has been carefully kept up to the fifty-fifth representative in the year 1740, when the country was seized without a struggle by the Marhattás of Nágpur. From 1818 to 1830 Bilaspur came under the management of the British Government, the Marhattá chief of Nágpur being then a minor. In 1854 the country finally lapsed to the British Government, the chief having died without issue. During the Sepoy mutiny a hill chief of the district gave some trouble, but he was speedily captured and executed.

BILÁSPUR, the chief town of the district of the same name, is situated on the south bank of the River Arpá. It is said to have been founded by a fisherwoman, named Bilása, three hundred years ago, and still retains her name. The place, however, came to note only about one

hundred years ago, when a Marhattá official took up his abode there, and began to build a fort which was never completed. In 1862 it was made the headquarters of the district, and is now a rising town. It lies in 22° 2′ N. lat. and 82° 5′ E. long. The population was estimated in 1870 at 6190, but Biláspur is not mentioned in the census of 1872 as containing upwards of 5000 inhabitants.

BILBAO, one of the principal cities of Spain, and capital of the province to which it gives its name, is situated in 43° 14′ N. lat. and 2° 56′ W. long., in a small but beautiful and fertile valley, bounded on three sides by mountains, about six miles from the sea, on the banks of the River Ansa, which is also known as the Nervion, or, in Basque, as the Ibaizabal. The old town lies on the left bank, while the new town, which is by far the more important, rises on the right in handsome terraces. Communication across the river is afforded by several bridges, of which the oldest, San Antonio, is of stone, and dates from the 14th century; the second was finished in 1827, the third in 1847, and the fourth, an iron structure, in 1868. The houses in the principal streets are built of hewn stone, and are several stories high, with projecting eaves that give shelter both from sun and rain. Many of the streets are very narrow, and they have an appearance of cleanliness and quiet. For a long time no carts or carriages were permitted to enter the city for fear of polluting and injuring the pavement, and the transport of goods was carried on in trucks. The principal promenades are the Paseo del Arenal, which lies along the right bank of the river, the Campo Volantin in the same neighbourhood, and the Paseo de los Caños, so called from its forming the roof of the great aqueduct for conveying the water of the river to the town. The public buildings comprise several churches, of which the oldest, Santiago, is of earlier date than the city itself, the town-hall, the palace of the *Diputacion Provincial*, an arsenal, a hospital, a theatre, and an abattoir. Of the educational institutions the most important are the *Colegio General de Vizcaya*, a nautical academy, and the schools supported by the board of trade for gratuitous instruction in design, architecture, languages, and mathematics. A bank of issue and discount was founded in 1857. The industrial establishments include iron and steel foundries (for which the town was at one time famous), anchor-forges, potteries, glass works, paper mills, and a cotton factory; and leather, sail-cloth, ropes, and tobacco are also manufactured. The exports consist mainly of grain and flour, iron, zinc, and lead ore, wine, madder, liquorice, lamb and goat skins, chestnuts, and oil. The wool trade has ceased for many years, and shipbuilding has greatly declined. A great stimulus was given to the import trade by the construction of the Bilbao and Tudela railway, which was completed in 1863; but the prosperity of the place is hindered by its distance from the sea. Large sums of money have been spent in improving the river, but ships of any size have to discharge at Portugalete, the average depth on the bar being 13½ feet at high tides. In spite of this disadvantage, however, Bilbao ranks as one of the principal trading ports in Spain. In 1870 the total tonnage of the ships that entered was 160,952, and the value of the imports amounted to £2,075,900. There is regular steam communication with London and Liverpool. Population, 17,649. Bilbao, or Belvao, was founded about 1300 by Don Pedro Lopez de Haro, and soon rose into importance. It was captured by the French in 1795, and was again held by them from 1808 to 1813. During the Carlist contest it was gallantly defended against Zumalacarregui in 1835.

BILDERDIJK, Willem, a modern Dutch poet, by some considered to be the most eminent that his country has produced, was born at Amsterdam in 1756. In 1776, after completing a wide course of study at Leyden University, he gained the prize from the Leyden Society of Art for his poem on the *Influence of Poetry on States and Governments*. In the following year he gained another prize for his poem *Love of Fatherland*, and in 1779 he translated the *Œdipus Tyrannus* of Sophocles. In 1786 he left Holland on account of the disturbed state of public affairs, and after residing some time in Germany crossed to England, where he remained till 1806. Returning then to his native country he was received with great favour by the new king Louis Napoleon, who made him president of the recently founded Institute of Holland. He died on the 18th December 1831. His finest poetical works are the *Buitenleven*, or Rural Life, a free imitation of Delille; *De Mensch*, similarly taken from Pope; *Die Ziekte der Geleerden*, the Maladies of the Learned; *Die Ondergang der eerste Wereld*, the Destruction of the First World. Some of his dramatic and epic poems are also highly esteemed. His second wife, besides some original work, translated the *Roderick* of Southey, who was very intimate with Bilderdijk, and resided for some time with him.

BILE. See Nutrition and Physiology.

BILFINGER, George Bernhard, was born on the 23d January 1693, at Cannstadt in Würtemberg. His father was a Lutheran minister. By a singularity of constitution, hereditary in his family, Bilfinger came into the world with twelve fingers and as many toes. From his earliest years he showed the greatest inclination to learning. He studied in the schools of Blaubeuern and Bebenhausen, and afterwards entered the theological seminary of Tubingen. The works of Wolff, which he studied in order to learn mathematics, soon inspired him with a taste for the Wolffian philosophy and that of Leibnitz,—a passion which made him neglect for some time his other studies. Returning to theology, he wished at least to try to connect it with his favourite science of philosophy; and in this spirit he composed the treatise entitled *Dilucidationes Philosophicæ, De Deo, Anima Humana, Mundo*, &c. This work, containing nothing original, but giving an admirably clear representation of Wolff's philosophy, met with great success, and contributed to the advancement of the author, who was appointed soon after to the office of preacher at the castle of Tubingen, and of reader in the school of theology. He soon after left for Halle, in order to attend the lectures of Wolff; and, after two years of study, returned to Tübingen, where the Wolffian philosophy was not yet in favour. He found his protectors there cooled, saw his lectures deserted, and perceived himself shunned, from the dislike of his new doctrines; his ecclesiastical views also suffered from the same cause. By the intervention of Wolff he received an invitation to Petersburg, where Peter I. wished to appoint him professor of logic and metaphysics, and member of his new academy. He was received in that city, where he arrived in 1725, with the consideration due to his abilities. The Academy of Sciences of Paris having proposed about this time the famous problem on the cause of gravity, Bilfinger gained the prize, which was a thousand crowns. His reputation was so much increased by this success that he was almost immediately recalled to his native country by the Duke Eberhard Ludwig of Würtemberg. He quitted St Petersburg in 1731, and in 1735 the Duke Charles Alexander appointed him privy councillor. After careful preparation Bilfinger entered on the duties of his new office, and soon approved himself one of the best and most enlightened ministers that his country had yet produced. Under his wise administration the commerce, public instruction, and agriculture of Würtemberg flourished, and the state was raised to a position it had not before attained. Bilfinger died at Stuttgart on the 18th February 1750.

BILL means generally a statement in writing, and is derived from the Latin *bulla*. The word is used in a great many special applications.

BILL, in *Parliament*, is a form of statute submitted to either House, which, after passing both Houses and receiving the royal assent, becomes an Act. The modern system of legislating by means of bill and statute appears to have been introduced in the reign of Henry VI., superseding the older mode of proceeding by petitions from the Commons, assented to by the king, and afterwards enrolled by the judges. A bill consists of a preamble, reciting the necessity for legislation, and causes which contain the enactments. The procedure with regard to bills is much the same in both Houses. Leave having been obtained, the bill is presented by the member in charge of it, and the first reading is usually allowed without opposition. At the second reading the principle of the bill is placed in issue; the usual form of amendment is that the bill be read a second time that day three or six months, the direct rejection of bills being incompatible with the courtesy of the House. The next stage is the committee, in which the different clauses are gone through in detail by the House sitting under the presidency of a chairman of committees. Two principles must be observed in reference to amendments:—(1), The amendment must not be irrelevant to the subject-matter of the clause; nor (2), must it propose to leave out all the words of the clause after the initial "That" in order that new words may be introduced. The bill having been fully considered the committee rises, the speaker resumes the chair, and the chairman of committee reports the bill to the House, which is up to this time supposed to be ignorant of the proceedings of the committee. A bill may be referred to a select committee (the course followed with private bills) or recommitted as often as the House desires. On the third reading the judgment of the House is expressed on the entire bill as it leaves the hands of the committee; and after the third reading the motion that the bill do pass is usually allowed without opposition. The bill is then communicated to the other House, where it passes through the same stages. Should the one House make amendments on a bill sent up by the other, the latter considers the amendments, and if they are not agreed to the bill is laid aside, or postponed for three or six months, or a message is sent with reasons for disagreement, or a conference between the Houses is requested. Having passed through both Houses the bill receives the royal assent, and therewith the "complement and perfection of a law." Bills are divided into public and private; the latter includes every bill for "the particular interest or benefit of any person or persons," whether individuals or corporations. They are brought in upon the solicitation of parties interested, and the payment of fees is an indispensable element of their progress. Occasionally there is some difficulty in assigning a bill to its proper class, *e.g.*, in bills relating to the metropolis, which, on account of the magnitude of the interests involved, are sometimes treated as public bills, although having, according to the definition, a purely private character. Private bills are subject to special regulations, and in case of opposition the proceedings before the select committees assume the form of an ordinary litigation. The chairman of committees in the Lords, and the chairman of ways and means in the Commons, are required to watch unopposed bills. Certain bills can only originate in one or other of the two Houses, *e.g.*, money bills in the House of Commons, and bills for the restitution of honours and blood in the House of Lords; and any bill concerning the privileges of either House should originate in the House to which it relates.

A BILL OF EXCHANGE is defined as "an unconditional written order from A to B, directing B to pay to C a sum certain of money therein named." A is called the drawer, B the drawee, and C the payee. When the drawee has undertaken to pay the bill he is called the acceptor. Contrary to the general rule in the law of England the benefit of a contract arising on a bill of exchange is assignable, and consideration will be presumed unless the contrary appear. Bills of exchange are believed to have been in use in the 14th century, but the first recorded decision of an English court regarding them occurs in the reign of James I. The courts long regarded them with jealousy as an exception to the common law, and restricted their use to the class of merchants, but their obvious utility overcame the scruples of the judges. The law on this subject has been evolved in a long series of judicial decisions. The following are a few of its leading principles:—A bill to be transferable must contain a direction to the *order* of the payee or to *bearer*. If payable to order it must be transferred by endorsement; but if to bearer, it may be transferred by mere delivery. A *blank* endorsement (*e.g.*, the mere signature of the endorser) makes the bill payable to bearer; a special endorsement directs payment to a person named, or his order. Every endorser of a bill is in effect a new drawer, and is liable to every succeeding holder in default of acceptance or payment. Just as the original drawer contracts to pay the payee, if the acceptor do not, so the endorser contracts that, if the drawee shall not pay the bill, he, on receiving due notice of the bill being dishonoured, will pay the holder what the drawee ought to have paid. An endorsement is held to admit "the signature and capacity of every prior party," and an endorser, in default of acceptance or payment, has a right of action against all those whose names were on the bill when it was endorsed to him. When a bill is transferred by delivery without endorsement it is generally regarded as sold, and the instrument is taken with all its risks. There are, however, some exceptions to this rule, as in the case of payment by bill for a precedent debt, &c., and the transferor will be held responsible if he knows at the time of sale that the bills are good for nothing. When a bill is payable to *bearer* it circulates like money, and the *bona fide* possessor is considered the true owner. Bills should be presented as soon as possible to the drawer or his agent for acceptance, which must be in writing on the bill. They should be presented for payment at the proper time, and the laws of commercial countries usually allow three *days of grace* after the day on which the bill becomes due. If the bill is not duly presented by the holder, the antecedent parties are relieved from liability. If the bill is not accepted, or after acceptance not paid, the holder must give *notice of dishonour* to the antecedent parties within a reasonable time, otherwise their liability will be discharged. When a foreign bill is dishonoured the custom of merchants requires that it should be *protested*. The protest is a solemn declaration by a notary written under a copy of the bill that payment or acceptance has been demanded and refused. Bills and notes, by the usage of trade, carry interest from the date of maturity. If in an action on a bill it turn out that the bill has been lost, the action may still be maintained provided that an indemnity is given against the claims of any other persons upon the instrument. The Act 18 and 19 Vict. c. 67, gives a summary process to the plaintiff in an action on a bill of exchange or promissory note commenced within six months after the same has become due or payable. Unless the defendant has obtained leave to appear and has appeared to the action, the plaintiff may sign final judgment for the amount with costs. The defendant, if he wishes to defend the action, must pay the money into court or show by affidavit such facts as may be sufficient to induce the judge to give him leave.

Foreign Bills (as distinguished from Inland Bills) are

bills drawn or payable abroad. By 19 and 20 Vict. c. 97, § 7, bills or notes drawn on one part and payable in any other part of the British Isles are inland bills. Foreign bills are usually drawn in sets or parts, each containing a condition to be payable only so long as the others continue unpaid.

When a bill is accepted by the drawee without consideration, and merely in order that the drawer may be able to raise money upon it, it is called an *accommodation* bill. Both parties are liable to the holder; but, as between themselves, the drawer is the principal and the acceptor a sort of surety. When acceptance has been refused and the bill protested, a stranger may accept it "*supra protest*, in honour of the drawer or endorser." The effect of this is to render the acceptor liable if the drawer does not pay, and the party for whose honour it was made, and parties antecedent to him, become liable to the acceptor. Payment for the honour of one of the parties may likewise be made by a mere stranger when a bill has been protested for non-payment, who thereupon acquires a claim against such person and all those to whom he could have resorted.

The negotiability of promissory notes and bank cheques is for the most part regulated by the same principles as bills of exchange. A promissory note is a "promise in writing to pay a specified sum at a time therein limited, to a person therein named or his order or to bearer." Cheques which are inland bills of exchange drawn on a banker have become subject to certain peculiar usages. See Exchange.

A Bill of Lading is a document signed by the master of a general ship and delivered to the owners of goods conveyed therein. It is usually made out in several parts or copies, of which the shipper retains one and sends one or more to the consignee, while the master keeps one for his own guidance. The following is the usual form:—Shipped in good order and well conditioned by [*A. B., merchant*] in and upon the good ship called [*The Good Intent*], whereof [*C. D.*] is master for this present voyage, and now riding at anchor in the [*Port of Southampton*], and bound to [*Cadiz in Spain, twenty cases of hardware and fifty bales of cotton goods*], being marked and numbered as in the margin, and are to be delivered in the like good order and well conditioned at the aforesaid port [*of Cadiz*], the act of God, the Queen's enemies, fire, and all and every other dangers and accidents of the seas, rivers, and navigations of whatever kind or nature whatsoever excepted, unto [*E. F., merchant*], or to his assigns, he or they paying freight for the said goods [ ] per case, and [ ] per bale freight, with primage and average accustomed. In witness whereof, &c.

Every bill of lading requires a sixpenny stamp. By the mercantile law a bill of lading is a negotiable instrument, and the property in the goods may be transferred by endorsement. By 18 and 19 Vict. c. 111, every consigner of goods named on a bill of lading, and every endorser to whom the property of the goods mentioned therein passes by reason of the consignment or endorsement, shall have transferred to and invested in him all rights of suit, and be subject to the same liabilities in respect of the goods as if the contract contained in the bill of lading had been made with himself.

A Bill of Sale is an assignment of personal property. It is frequently made by way of security, the property remaining in possession of the vendor. For the protection of creditors from secret or fraudulent sale, the Bills of Sale Act, 1854, and the Amendment Act, 29 and 30 Vict. c. 96, were passed. By these Acts a bill of sale of personal chattels made at any time by a defendant in an action will be void as against a plaintiff on whose behalf a writ of execution in such action shall be sued out and delivered, so far as regards any personal chattels in defendant's possession at or after the time of executing such writ, unless such bill of sale shall be duly registered for public inspection in the Court of Queen's Bench within twenty-one days of its date. The registration must be renewed once in every five years during the subsistence of the security.

Bill in Chancery. A suit in the Court of Chancery was generally commenced by a bill, addressed to the lord chancellor, containing a statement of the plaintiff's case, and praying for relief. By the Chancery Amendment Act, 1862, it is enacted that "every bill shall contain as concisely as may be, a narrative of the material facts, matters, and circumstances on which the plaintiff relies; such narrative being divided into paragraphs numbered consecutively, and each paragraph containing as nearly as may be a separate or distinct statement or allegation; and shall pray specifically for the relief which the plaintiff may conceive himself entitled to, and also for general relief." By the Judicature Act, 1873, a new form of procedure is established for all the superior courts. See Action. (E. R.)

BILLETING. The law as to billeting soldiers is regulated by the provisions of the Annual Mutiny Act (38 Vict. c. 7, §§ 63–67). Constables of parishes and places, police officers, high constables, and other chief officers and magistrates may billet officers and soldiers on actual service, with their horses and baggage, in victualling house, inn, hotel, livery stable, ale-house, or the house of any seller of wine by retail to be drunk in such house, or the houses of persons selling brandy, spirits, strong waters, cider, or metheglin by retail; but no officer or soldier shall be billeted in any private houses, or in any canteen under the authority of the War Department, nor on persons keeping taverns only being vintners of the city of London, nor on distillers, nor on shopkeepers whose principal dealing is more in other goods than in brandy and strong waters, so as such distillers and shopkeepers do not permit tippling in such houses. If the victualler has not sufficient accommodation in his own house he must find it in the immediate neighbourhood. The following sums are allowed as compensation:—For hot meal, to be supplied each day to soldiers on the march, 10d., with 2½d. for a bed; for other soldiers, entitled to bed, candles, use of fire and cooking utensils, 4d. per diem for each soldier; for ten pounds of oats, twelve of hay, and eight of straw, 1s. 9d. per diem. Military officers must not act as justices in billeting.

BILLIARDS is a well-known indoor game of skill, played on a rectangular table with ivory balls, which are driven into pockets and against each other according to certain defined rules. Of the origin of billiards comparatively little is known,—some considering that the game was invented by the French, and others that it was improved by them out of an ancient German diversion. Even the French themselves are doubtful on this point; for, while it is generally asserted that Henrique Devigne, an artist, who lived in the reign of Charles IX., gave form and rule to the pastime, the *Dictionnaire Universel* and the *Académie des Jeux* ascribe its invention to the English. Bouillet in the first work says—"Billiards appear to be derived from the game of bowls. It was anciently known in England, where, perhaps, it was invented. It was brought into France by Louis XIV., whose physician recommended this exercise." In the other work quoted we read—"It would seem that the game was invented in England." Strutt, a rather doubtful authority, notwithstanding the reputation attained by his *Sports and Pastimes of the People of England*, considers it probable that it was the ancient game of Paille-maille on a table instead of on the ground or floor,—an improvement, he says, "which answered two good purposes: it precluded the necessity of

the player to kneel or stoop exceedingly when he struck the bowl, and accommodated the game to the limits of a chamber." Whatever its origin, and whatever the manner in which it was originally played, it is certain that it was common in the time of Shakespeare, who makes Cleopatra, in the absence of Antony, invite her attendant to join in the pastime—

"Let us to billiards :
Come, Charmian."—*Ant. and Cleo.* Act. ii. sc. 5.

Billiards was originally played, it seems, in a method even now adopted in the rustic game of Rural Billiards, by driving a ball through a ring which revolved on a pin or stick fixed to the table or floor. In Cotton's *Compleat Gamester*, published in 1674, we are told that this "most gentile, cleanly, and ingenious game" was first played in Italy, though in another page he mentions Spain as its birthplace. At that date billiards must have been well enough known, for we are told that "for the excellency of the recreation, it is much approved of and played by most nations of Europe, especially in England, there being few towns of note therein which hath not a public billiard table, neither are they wanting in many noble and private families in the country." Since Cotton every compiler of books on games has had more or less to say about billiards; though, curiously enough, Hoyle, who is often quoted as an authority, makes no mention whatever of the game. It is only in the later editions and continuations of Hoyle that billiards, bagatelle, cricket, &c., find place. It is not, indeed, till our own days that anything like a scientific treatise on billiards has appeared, or that the game itself has been lifted out of the tavern—whence, in spite of its historians' praises, it gradually descended—to its present more favoured position as a harmless and amusing indoor game.

The Table.—The shape of the table has varied from time to time, probably to suit the dimensions of the room in which it was placed. At first it was square, with a hole or pocket at each corner to receive the balls driven forward with a cue or mace; then it was lengthened and provided with two other pockets; and occasionally it has been made round, oval, triangular, or octagonal, with or without pockets according to the game required. The cannon game in France is played on a pocketless table 8 feet by 4; the same game of the United States is played on a table 10 feet by 6, commonly made without pockets; but in England the regular table of the clubs and public rooms is a massive structure of timber, with a bed or surface of slate or metal 12 feet long by 6 feet wide, or two equal squares of 5 feet 10½ inches across within the cushions. It is covered by a fine green cloth, and surrounded by elastic india-rubber cushions, at the junctions of which are netted pockets—one at each corner, and one midway at each of the longer sides. The table must be perfectly level and sufficiently firm to prevent vibration; and its usual height from the floor to the surface is 3 feet. The space required between table and wall is at least four feet. Smaller tables for use in private houses have lately been introduced. Whether large or small, each table is provided with a baulk line and semicircle and several marks or spots to regulate the mode of play. The baulk line is drawn straight across the table 28 inches from the bottom or lower cushion, and from it is struck a semicircle of from 21 to 23 inches in diameter. In the middle of the baulk line is the baulk spot, and in the middle of the table the centre spot. Thirteen inches from the top cushion is the red-ball spot, and half-way between the centre and the top cushion is the pyramid spot,—all these spots being on a line which, if drawn from end to end, would divide the table into two oblong halves.

Games.—The principal games are three in number,—billiards proper, pyramids, and pool; and from these spring a variety of others. The object of the player in each game, however, is to drive one or other of the balls into one or other of the pockets, or to cause the striker's ball to come into successive contact with two other balls. The one stroke is known as a hazard, the other as a cannon; and from hazards and cannons, together with misses, forfeitures, and foul strokes, are reckoned the points of the game. When the ball is forced into a pocket the stroke is called a winning hazard; when the striker's ball falls into a pocket after contact with the object ball, the stroke is a losing hazard; and these hazards count two or three to the player's score according as they are made from the white or the red ball—two points for the white, three for the red. Two points are scored for the cannon, three for a *coup*—a term used when the player's ball runs into a pocket without striking a ball; and one point for a miss, whether given purposely or accidentally. These strokes are all made with a cue, which is a long stick of ash, or other hard wood, gradually tapering to the end, which is tipped with leather and rubbed with chalk to prevent it slipping off the surface of the ball struck. The mace or hammer-headed cue, once common, is no longer used, even by ladies. The cue is taken in the right hand, generally between the fingers and thumb, and not grasped in the palm; and with the left hand the player makes a bridge, by resting the wrist and the tips of the fingers on the table, arching the latter, and extending the thumb in such a way as to allow a passage in which the cue may slide. The player then proceeds with his game, according to the following rules:—

Billiards proper, or the English game, consists of winning and losing hazards, cannons, and forfeitures. It is usually played 50 or 100 points, reckoned as already explained, three for each red hazard, two for each white hazard, and two for each cannon. Public matches between adepts are played 100, 500, or 1000 up, but the rules which govern them are the same. The remarks within brackets are explanatory.—1. The game of billiards proper commences by stringing for the lead and choice of balls. [The players standing behind the baulk line, strike each a ball from the semicircle up to the top cushion, and he whose ball on its return stops nearest the bottom cushion has the choice of lead and balls.] 2. The red ball is placed on the spot at the commencement of the game, and replaced when it is pocketed or forced over the table. ["Breaking the balls" is the replacing them as at the beginning of a game. The balls are said to be "broken" when the first player has struck the red or given a miss; and the player's ball when off the table is said to be "in hand."] 3. The player who makes one stroke in a game must finish that game or consent to lose it. [Intended to meet cases of dispute.] 4. In the case of foul strokes, the adversary has the option of either allowing the striker to proceed, of having the ball replaced, or of breaking the balls. No score can be reckoned for a foul stroke. [The following are foul strokes:—If the player move a ball in the act of striking; if he play with the wrong ball; if he touch a ball twice in making a stroke; if he play at a ball while it is running; if he touch a ball with his hand, cue, or person, otherwise than is necessary for the stroke; if he in any way touch his opponent's ball.] 5. If the adversary neglect to observe or to claim a foul stroke, the player proceeds with his game, and all the points he makes are marked. 6. If a ball spring from the table and hit a bystander, so as to prevent it falling to the floor, it is considered off the table. [The penalty in such a case is that the other player goes on, or if the ball has not struck another ball before flying off the table, the loss of three points, as for a coup.] 7. Balls lying within the baulk line cannot be played at with a ball in hand, except the player whose ball is in hand first play at a cushion beyond or outside the baulk line. 8. A line-ball cannot be played at by the striker whose ball is in hand, other than by playing his ball out of baulk against a cushion. [A line-ball is when the centre of the ball's surface lies exactly on the line across the table. The marker or umpire must decide as to whether such ball is within or without the line.] 9. A ball in hand striking a ball in baulk without having been first played out of baulk, must be replaced and played over again. 10. All misses must be given with the point of the cue. [This rule is sometimes neglected, and the player allowed to give his miss with the butt end of his cue.] 11. Should the spot be occupied so that the red ball cannot be placed on it after being pocketed, it must be placed on the centre spot, or, if that also be occupied, on the pyramid spot. [In some clubs the custom is to place the red ball on the centre spot, or on the baulk line spot, ac-

cording to agreement.] 12. No points are reckoned for a ball or balls forced off the table after contact with the object-ball, and the adversary goes on without breaking the balls. 13. If the balls be changed in the course of play, no cannon or hazard made with such changed ball can be scored; the balls must be broken, and all points made with the wrong ball deducted from the striker's score. [In such case, however, the adversary has the privilege of playing with the changed ball, of re-changing the balls and playing on from their respective positions, or of having the balls broken.] 14. The player whose ball is in hand cannot score, unless he play his ball out of baulk before striking the object-ball. [In such case the stroke must be remade.] 15. If in drawing back his cue from a ball on the brink of a pocket the striker hole his ball, he loses three points, as for a coup. 16. A ball accidentally moved by the marker or a looker-on must be replaced. 17. A ball wilfully removed or obstructed in its course causes the loss of the offender's game. 18. If the striker's ball be touching his opponent's ball, or the red ball, no score on that side can follow. [After the stroke the next player proceeds with his game, either by breaking the balls, or playing from the spot where his ball stopped. When balls touch, the player may either run into a pocket, or play on to a third ball; then the red is spotted and the adversary plays on from baulk; or if the first player fail to do either, the balls remain as they fall, and the other goes on.]

These, with the exception of some remarks about the conduct of strangers, the payment of wagers, and so on, are the rules by which the English game of billiards is universally governed. The principal modifications of this game are the four-handed game, which is ordinary billiards by four players in sides of two, each player being allowed to instruct his partner; à la royale, or the game of three; the white winning game, consisting entirely of winning hazards; the white losing game; the red winning game; the red losing game; the cannon game; and the American game. This last is played with four balls, two white and two coloured, and consists entirely of winning hazards and cannons. There is also a Russian game, called carline or caroline, not unlike American billiards; a German game, *Wurst-partie*, in which a certain number of balls are placed in a row across the table; the Spanish, or skittle game, which the Germans call *Kugel-partie;* and French billiards or the cannon game formerly universal on the Continent, and now very popular in the United States, where the best players are Frenchmen or men of French extraction. Of these games, however, it is unnecessary to speak, as they are all much inferior to billiards, and can be easily played by any one familiar with the established English game. The lesser varieties of billiards—choice of balls, in which each player selects the ball he plays with; bricole, in which the player strikes his ball against a cushion and endeavours to reach his opponent's ball from the rebound; bar-hole, so called from a pocket or pockets being barred or stopped for one of the players; one pocket to five; winning against losing; the nomination game, which is ordinary billiards, in which the player is obliged to name his stroke before attempting it, and failing to make it gains nothing, or gives unnamed cannons and hazards to his opponent; the commanding game; the go-back game, which is played by an adept against a tyro, the latter scoring all he makes and the former going back to nothing every time his adversary makes a winning or losing hazard;—all these are so barren of interest and so seldom played as barely to deserve mention.

As to the science of the game, there is really little to be taught in books; practice and instruction from an adept will better enlighten a tyro as to the mysteries of the side-stroke, the drag, the screw, the following ball, the spot-stroke, &c., than any amount of verbal explanation. It may, however, be as well to refer briefly to these several points, in order to render this notice as complete as the space at command will admit.

The *side-stroke* is made by striking the object-ball on the side with the point of the cue. The effect of such a mode of striking the ball is to make it travel to the right or to the left, according as it is struck with a winding or slightly circular motion; and its purpose is to cause the ball to proceed in a direction more or less slanting than is usual, or ordinary, when the ball is struck in or about the centre of its circumference. Many hazards and cannons, quite impossible to be made with the central stroke, are accomplished with ease and certainty by the side-stroke. In the hands of a dexterous player this stroke is both elegant and effective. The *screw,* or twist, is made by striking the ball low down, with a sharp, sudden blow. According as the ball is struck nearer and nearer to the cushion, it stops dead at the point of concussion with the object-ball, or recoils by a series of reverse revolutions, in the manner familiar to the schoolboy in throwing forward a hoop, and causing it to return to his hand by the twist given to its first impetus. The *following-ball* is made by striking the ball high, with a flowing or following motion of the cue. Just as the low-stroke impedes the motion of the ball, the follow expedites it. In the *drag* the ball is struck low without the sudden jerk of the screw, and with less than the onward push of the follow. The *spot-stroke* is a winning hazard made by pocketing the red ball in one of the corners from the spot. The great art is, first, to make sure of the hazard, and next, to leave the striking ball in such a position as to enable the player to make a similar stroke in one or other of the corner pockets. To such perfection has the spot-stroke been brought, that the winning hazard has been repeated more than two hundred and fifty times consecutively. W. Cook, the finest of English players, on November 29, 1873, in a game with the ex-champion, Joseph Bennett, made a break of 936, the longest on record. In this great performance Cook made, in all, no fewer than 292 spot-hazards, 260 of which were made consecutively. John Roberts, jun., of Manchester, has also made an extraordinary break, 800, the majority by the spot-stroke. Without the spot-hazard, the longest break hitherto made is probably less than 200.

The perfection of billiards is to be found in the nice combination of the various strokes, in such fashion as to leave the balls in a favourable position after each individual hazard and cannon; and this perfection can only be attained by the most constant and unremitting practice.

Pyramids is played by two or four persons—in the latter case in sides, two and two. It is played with fifteen balls, placed close together in the form of a triangle or pyramid, with the apex towards the player, and a white striking ball. The centre of the apex ball covers the second or pyramid spot, and the balls forming the pyramid should lie in a compact mass, the base in a straight line with the cushion.

Pyramids is a game entirely of winning hazards, and he who succeeds in pocketing the greatest number of balls wins. Usually the pyramid is made of fifteen red or coloured balls, with the striking ball white. This white ball is common to both players. Having decided on the lead, the first player, placing his ball in the baulk-semicircle, strikes it up to the pyramid, with a view either to lodge a ball in a pocket or to get the white safely back into baulk. Should he fail to pocket a red ball, the other player goes on and strikes the white ball from the place at which it stopped. When either succeeds in making a winning hazard, he plays at any other ball he chooses, and continues his break till he ceases to score; and so the game is continued by alternate breaks until the last red ball is pocketed. The game is commonly played for a stake upon the whole, and a proportionate sum upon each ball or life,—as, for instance, 3s. game, and 1s. balls. The player wins a life by pocketing a red ball or forcing it over the table; and loses a life by running his own, the white, ball into a pocket, missing the red balls, or intentionally giving a miss. In this game the baulk is no protection; that is to say, the player can pocket any ball wherever it lies, either within or without the baulk line, and whether the white be in hand or not. This liberty is a great and certain advantage under many circumstances, especially in the hands of a good player. It is not a very uncommon occurrence for an adept to pocket six or eight balls in a single break. Both Cook and Roberts have been known, indeed, to pocket the whole fifteen. If four persons play at pyramids, the rotation is decided by chance, and each plays alternately,—partners, as in billiards, being allowed to advise each other, each going on and continuing to play as long as he can, and ceasing when he misses a hazard. Foul strokes are reckoned as in billiards, except as regards balls touching each other. If two balls touch, the player proceeds with his game and scores a point for every winning hazard. When all the red balls but one are pocketed, he who made the last hazard plays with the white and his opponent with the red; and so on alternately, till the game terminates by the holeing of one or other ball. The pyramid balls are usually a little smaller than the billiard balls; the former are about 2 inches in diameter, the latter $2\frac{1}{16}$ inches to $2\frac{1}{4}$ inches.

Losing Pyramids, seldom played, is the reverse of the last-named game, and consists of losing hazards, each player using the same striking ball, and taking a ball from the pyramid for every losing

hazard. As in the other game, the baulk is no protection. Another variety of pyramids is known as *Shell-out*, a game at which any number of persons may play. The pyramid is formed as before, and the company play in rotation. For each winning hazard the striker receives from each player a small stake, and for each losing hazard he pays a like sum, till the game is concluded by pocketing the white or the last coloured ball.

Pool, a game which may be played by two or more persons, consists entirely of winning hazards. Each player subscribes a certain stake to form the pool, and at starting has three chances or lives. He is then provided with a coloured or numbered ball, and the game commences thus:—The white ball is placed on the spot and the red is played at it from the baulk semicircle. If the player pocket the white he receives the price of a life from the owner of the white; but if he fail, the next player, the yellow, plays on the red; and so on alternately till all have played, or till a ball be pocketed. When a ball is pocketed the striker plays on the ball nearest his own, and goes on playing as long as he can score.

The order of play is usually as follows:—The white ball is spotted; red plays upon white; yellow upon red; then blue, brown, green, black, and spot-white follow in the order of succession named, white playing on spot-white. The order is similar for a larger number, but it is not common for more than seven or eight to join in a pool. The player *wins* a life for every ball pocketed, and receives the sum agreed on for each life from the owner of that ball. He *loses* a life to the owner of the ball he plays on and misses; or by making a losing hazard after striking such ball; by playing at the wrong ball; by running a coup; or by forcing his ball over the table. Rules governing the game provide for many other incidents. A ball in baulk may be played at by the striker whose ball is in his hand. If the striker's ball be angled—that is, so placed in the jaws of the pocket as not to allow him to strike the previously-played ball—he may have all the balls except his own and the object ball removed from the table to allow him to try bricole from the cushion. In some clubs and public rooms an angled ball is allowed to be moved an inch or two from the corner; but with a ball so removed the player must not take a life. When the striker loses a life, the next in rotation plays at the ball nearest his own; but if the player's ball happen to be in hand, he plays at the ball nearest to the centre spot on the baulk line, whether it be in or out of baulk. In such a case the striker can play from any part of the semicircle. Any ball lying in the way of the striker's ball, and preventing him from taking fair aim and reaching the object-ball, must be removed, and replaced after the stroke. If there be any doubt as to the nearest ball, the distance must be measured by the marker or umpire; and if the distance be equal, the ball to be played upon must be decided by chance. If the striker first pocket the ball he plays on and then runs his own into a pocket, he loses a life to the player whose ball he pocketed, which ball is then to be considered in hand. The first player who loses all his three lives can "star;" that is, by paying into the pool a sum equal to his original stake, he is entitled to as many lives as the lowest number on the marking board. Thus if the lowest number be two, he stars two; if one, he stars one. Only one star is allowed in a pool; and when there are only two players left in, no star can be purchased. The price of each life must be paid by the player losing it, immediately after the stroke is made; and the stake or pool is finally won by the player who remains longest in the game. In the event, however, of the two players last left in the pool having an equal number of lives, they may either play for the whole or divide the stake. The latter, the usual course, is followed except when the combatants agree to play out the game. When three players are left, each with one life, and the striker makes a miss, the two remaining divide the pool without a stroke—this rule being intended to meet the possible case of two players combining to take advantage of a third. When the striker has to play, he may ask which ball he has to play at, and if being wrongly informed he play at the wrong ball, he does not lose a life. In clubs and public rooms it is usual for the marker to call the order and rotation of play: "Red upon white, and yellow's your player;" and when a ball has been pocketed, the fact is notified—"Brown upon blue, and green's your player, in hand;" and so on till there are only two or three players left in the pool.

There are some varieties of the game which need brief mention.

Single Pool is the white winning hazard game, played for a stake and so much for each of three or more lives. Each person has a ball, usually white and spot-white. The white is spotted, and the other plays on it from the baulk semicircle; and then each plays alternately, spotting his ball after making a hazard. For each winning hazard the striker receives a life; for each losing hazard he pays a life; and the taker of the three lives wins the game. No star is allowed in single pool. The rules regulating pool are observed.

Nearest Ball Pool is played by any number of persons with the ordinary coloured balls, and in the same order of succession. All the rules of pool are followed, except that the baulk *is* a protection. The white is spotted, and the red plays on it; after that each striker plays upon the ball nearest the upper or outer side of the baulk line; but if all the balls lie within the baulk line, and the striker's ball be in hand, he must play up to the top cushion, or place his ball on the spot. If his ball be not in hand, he plays at the nearest ball, wherever it may lie.

Black or *Everlasting Pool* is played by any number of persons in the ordinary way, except that the game is for lives only, without a subscribed stake. After the coloured balls are distributed a black ball is placed on the centre spot. At this the first striker plays. Any player, having pocketed a coloured ball, may play at the black; and if he succeed in holing it, he receives not only the life he took from the coloured ball, but the value of a life from each player. On the contrary, if he make a losing hazard off the black ball, miss it, or force his own ball off the table, he pays a life to each player. No ball can be removed to allow the striker to play on the black, but the latter may be removed to allow the striker to play at the proper object-ball. Any person may join the pool at any time, but cannot play in that round; and he may, on giving notice of his intention, retire at the end of a clear round, until which time his ball remains on the table, and stands its chance with the rest. The price per life is determined, as in the other pool games, previously to commencing; and it is usual for the marker or leader of the game to notify the conclusion of each clear round.

Skittle Pool is played by any number of persons with three balls, a red and two white, and twelve skittles—ten of which are white, and two black. The skittles and balls are arranged, according to a set design, on the table, and the game is played for small stakes determined by the number of skittles knocked over, *after* striking at a ball. It is an amusing, but unscientific game, encumbered with rules which cannot be understood without a diagram.

Penny Pot is the last of the pool games needing notice. It is played as ordinary pool, with the same order of rotation, by any number of players. Instead, however, of subscribing for a pool, and confining each player to three lives, there is no subscribed stake, and the players play on as long as they like, a penny being paid by the owner to the taker of each life; winning hazards receiving, and losing hazards, misses, and coups paying; each player proceeding in turn as in regular pool.

Much might be written on the scientific principles of the side-stroke, the angles of incidence and reflection, &c.; but the theories advanced on these topics would lead us farther into the region of mathematics than is necessary for a description of the several games played on the billiard table. The scientific features of billiards are discussed at more or less length in several of the following works:—*Practical Treatise on the Game of Billiards*, by E. White, 1807 (this was partly a translation of a French treatise, published in 1805, and partly a compilation from the article in the *Académie Universelle des Jeux*, issued in the same year, and since frequently re-edited and reprinted); *Le Musée des Jeux*, Paris, 1820; *The Noble Game of Billiards*, by Monsieur Mingaud, Paris, 1834; a translation of the same, by John Thurston, London, 1835; Kentfield *on Billiards*, London, 1839, founded principally on the foregoing works; *Billiards, Game 500 up*, by Edward Russell Mardon, London, 1849; Turner *On Billiards*, a series of diagrams with instructions, Nottingham, 1849; *The Billiard Book*, by Captain Crawley, London, 1866 75; Roberts *On Billiards*, 1868; *Practical Billiards*, by Fred. Hardy, edited by W. Dufton, 1867; *Billiards*, by Joseph Bennett, ex-champion, 1873. There are besides numerous handbooks of more or less value. (G. F. P.)

BILLITON, or BLITONG, an island of the East Indies, belonging to the Dutch, situated between Sumatra and Borneo, in lat. 3° S. and long 108° E. It is of a circular form, about 50 miles in length by 45 in breadth; and has an area, according to Melvill van Carnbée, of 2500 square miles. The weather is subject to rapid changes; but the usual temperature varies from 80° to 87° Fahr. The nights are very cool. The surface in the north is hilly,—Tadjem, the highest peak, being 3280 feet in height. The sea-coast is inaccessible and surrounded with rocks, and the best harbour is still that at the chief town of Tandjong Padan. The navigation between the island and Borneo is very dangerous. Horses, buffaloes, cattle, sheep and goats, ducks, geese, fowls, and pigeons are the domestic animals of Billiton; and among its wild animals are deer, goats, jackals, monkeys, civet-cats, tiger-cats, and porcupines. The seas furnish a superabundance of fish. On the rocks along the coast are found tortoises, trepang, and edible birds'-nests, which are articles of export. The forests supply wood of

See map of Sumatra

different kinds for shipbuilding, in which the inhabitants are very expert. There are important mines both of iron and tin, the former being used in the island and the latter exported to the Netherlands. The quantity of tin obtained in 1871 was 49,850 picols, or 60,532 cwts. The chief imports are rice, cotton goods, pottery, and cocoa-nuts. The population in 1871 amounted to 19,837, of whom only 59 were Europeans. The natives are of middle height and strongly built, and have expressive features. The island was formerly under the sultan of Palembang, by whom it was ceded to the English in 1812. As no mention was made of it in the treaty between the English and Dutch in 1814, the former at first refused to renounce their possession, and only recognized the Dutch claim in 1824. Till 1852 it was dependent on Banka, but at that date was raised to a sub-residency.

See *Tijdschrift v. Nederl. Indië*, vols. xii. and xv.; Court's *Relations of Brit. Gov. with the State of Palembang*, 1821; Croockewit, *Banka, Malakka, en Billiton*, 1852; Veth, *Woordenboek van Nederl. Indië*, 1869.

BILMA, or KAWAR, a town in the heart of the African desert, and the capital of the wandering tribe called the Tibboos. The place is mean and poor, surrounded with a mud wall. In its vicinity are a number of lakes, the waters of which, on evaporation by the heat of the sun, yield a quantity of very pure and fine salt, which is the object of an extensive and important trade with the countries in Central Africa. The largest of these lakes is at Agram, situated about four miles to the westward. Near Bilma is a small circular spot, kept green by a fine spring, but immediately to the south begins the most dreary part of the African desert, over which the caravans travel for fifteen days without discovering the slightest trace of vegetable life. During Nachtigal's visit in 1870 the temperature during the day rarely sank below 113° Fahr.

BILSA, a town of Hindustán, in the territory of Gwálior or the possessions of Sindhiá, situated on the Betwá River in lat. 23° 30′ N. and long. 77° 50′ E. It is enclosed with a stone wall, and defended by square towers and a ditch. The suburbs without the walls are not very extensive, but the streets are spacious, and contain some good houses. The town and the surrounding country are celebrated all over India for the excellent quality of the tobacco, which is bought up with great eagerness and exported. Population about 3000. Distance south from Gwálior, 190 miles.

BILSTON, formerly BILSRETON, a market-town of England, in the county of Stafford, 2½ miles S.E. of Wolverhampton, indebted for its importance to the iron trade, which it carries on in various departments. In the vicinity are very productive mines of coal and ironstone, as well as sand of the finest quality for casting, and grinding-stones for cutlers. Bilston contains numerous furnaces, forges, rolling and slitting mills for the preparation of iron, and a great variety of factories for japanned and painted goods, brass-work, bells, and similar articles. The town itself is very irregularly built; but it has some handsome buildings, as St Leonard's and St Mary's chapels, and the Roman Catholic chapel. The population of township, which is under an improvements commission, and forms part of the parliamentary borough of Wolverhampton, was, in 1871, 24,188.

BINGEN, the ancient *Bingium*, a town of the grand-duchy of Hesse-Darmstadt, in the province of Rhenish Hesse, 15 miles W. of Mentz. It is situated almost opposite Rüdesheim, on the left bank of the Rhine, at the confluence of the Nahe (or *Nava*), which is crossed near its mouth by an iron railway bridge resting on old Roman foundations. A considerable trade is carried on in wine, grain, and cattle; and tobacco, starch, and leather are manufactured. A short way down the Rhine is the Bingerloch, a famous whirlpool, the dangers of which were almost removed by blastings undertaken by the Prussian Government in 1834; while about half-way between it and the town rises on a rock, in the middle of the stream, the tower of Bishop Hatto. On a height immediately to the south-east is the ruined castle of Klopp, originally founded by Drusus, and higher still on the Rochusberg the celebrated chapel of St Roch. Population in 1871, 5938.

BINGHAM, JOSEPH, a learned scholar and divine, was born at Wakefield in Yorkshire, in September 1668. He was educated at University College, Oxford, of which he was made fellow in 1689, and college tutor in 1691. A sermon preached by him from the university pulpit, St Mary's, on the meaning of the word "Person" in the Fathers, brought upon him a most unjust accusation of heresy. He was compelled to give up his fellowship and leave the university; but he was immediately presented by Dr John Radcliffe to the rectory of Headbournworthy, near Winchester. In this country retirement he began his laborious and valuable work entitled *Origines Ecclesiasticæ*, or Antiquities of the Christian Church, the first volume of which appeared in 1708 and the tenth in 1722. Notwithstanding his learning and merit, Bingham received no higher preferment than that of Headbournworthy till the year 1712, when he was collated to the rectory of Havant, near Portsmouth, by Sir Jonathan Trelawney, bishop of Winchester. Nearly all his little property was lost in the great South Sea bubble of 1720. He died August 17, 1723.

BINGLEY, a thriving market-town in the West Riding of Yorkshire, on the River Aire, 5½ miles from Bradford, on the Midland Railway. The inhabitants are principally engaged in manufactures of worsted, cotton, paper, and iron. The town is well built, and has a neat church, a grammar school, and several charities. The population of the Local Board District, which includes a part of Micklethwaite, was 9062 in 1871.

BINNEY, THOMAS, an English Nonconformist divine, was born at Newcastle-on-Tyne in 1798, and died February 24, 1874. After spending seven years in the employment of a bookseller he entered the theological college of Wymondley, Herts, with the view of studying for the ministry. His first pastoral charge was that of the Congregational church at Newport, Isle of Wight, to which he was inducted in 1824. Five years later—in 1829—he accepted a call to the historic Weigh House chapel, London. Here he at once established what proved to be a lasting popularity, and it was found necessary to build a much larger place of worship on Fish Street Hill, to which the congregation removed in 1834. An address delivered on the occasion of the laying of the foundation stone of the new building was afterwards published, with an appendix containing a strongly worded opinion as to the baneful influence of the Church of England, which naturally gave rise to much angry comment and a prolonged and bitter controversy. Throughout his whole career Binney was a vigorous and intelligent opponent of the state church principle, but those who inferred from one, perhaps unguarded, statement that he was a narrow-minded political dissenter did him injustice. His liberality of view and breadth of ecclesiastical sympathy entitle him to rank on questions of Nonconformity among the most distinguished of the school of Richard Baxter. Accordingly, in his later years he was not only recognized by general consent as the foremost name among all sections of English Nonconformists, but maintained friendly relations with many of the leading dignitaries of the Established Church. He continued in the active discharge of the duties of the ministry, though latterly with the help of a colleague, until 1871, when he resigned. In 1845 he paid a visit to Canada and the United States, and in 1857 he set out on a tour to the Australian

colonies, which extended over a period of two years. Though he not infrequently fell markedly below his own standard of excellence, Binney exercised an influence as a preacher, especially with young men, such as few have wielded for so long a period. A manly, vigorous intellect, fearless independence of judgment, a lively imagination, showing itself chiefly in frequent flashes of happy illustration, a keen, sarcastic humour chastened but of deliberate purpose not altogether repressed, a direct forcible style, a commanding presence, and a pleasant musical voice sufficiently account for his popularity. He was the pioneer in a much needed improvement of the forms of service in Nonconformist churches, and gave a special impulse to congregational psalmody by the publication of a book entitled *The Service of Song in the House of the Lord.* Of numerous other works the best known is his *Is it Possible to Make the Best of Both Worlds?* an expansion of a lecture delivered to young men in Exeter Hall, which attained a circulation of 30,000 copies within a year of its publication. A very happy specimen of his peculiar powers as an author is his *Money, a Popular Exposition in Rough Notes* (1864), which also had a large circulation.

BINTANG, one of the islands which mark the south side of the Strait of Singapore. The latter is the exit towards China and Siam of the great channel which we call the Straits of Malacca. Bintang lies between 104° 13′ and 104° 40′ E. long., with a central latitude of 0° 52′ N. It has an area of about 440 square miles, and is surrounded by many rocks and small islands, making navigation dangerous. The soil is not fertile, and much of it is swampy. The chief product is *gambir*, of which upwards of 4000 tons are annually exported, with pepper and some other spices and fruits. The island is a good deal visited by Malay and Chinese traders. The highest hill in it is 1385 feet high, and there are five rivers, but these navigable only by small boats.

Bintang is mentioned by Marco Polo under the name of *Pentam*, which is not far from the genuine Malay name *Bentăn*, said to mean a half-moon, and to apply properly to the mountain just mentioned. The name appears on a mediæval Javanese inscription, as that of one of the numerous kingdoms conquered by the sovereigns reigning at Majapahit, in Java.

After the Portuguese conquest of Malacca (1511), the expelled Mahometan dynasty took up its residence on Bintang, where it long cherished pirates. The island still belongs nominally to the representative of these kings of Malacca, whom we usually style the sultan of Johór, the Dutch the sultan of Lingen. Supremacy is, however, claimed and exercised by the Dutch, whose port of *Rhio* or *Riouw*, founded as a rival to Singapore, stands on a small island off the western coast of Bintang.

Bintang, regarded as the residence of the expelled sultans of Malacca, is the Bintão whereof Camoens speaks as the persistent foe of Portuguese Malacca:-

"*No reino de* Bintão, *que tantos danos*
Terá a Malaca muito tempo feitos."

BIOLOGY

Scope of Biology.

THE Biological sciences are those which deal with the phenomena manifested by living matter; and though it is customary and convenient to group apart such of these phenomena as are termed mental, and such of them as are exhibited by men in society, under the heads of Psychology and Sociology, yet it must be allowed that no natural boundary separates the subject matter of the latter sciences from that of Biology. Psychology is inseparably linked with Physiology; and the phases of social life exhibited by animals other than man, which sometimes curiously foreshadow human policy, fall strictly within the province of the biologist.

On the other hand, the biological sciences are sharply marked off from the abiological, or those which treat of the phenomena manifested by not-living matter, in so far as the properties of living matter distinguish it absolutely from all other kinds of things, and as the present state of knowledge furnishes us with no link between the living and the not-living.

The properties of living matter.

These distinctive properties of living matter are—

1. Its *chemical composition*—containing, as it invariably does, one or more forms of a complex compound of carbon, hydrogen, oxygen, and nitrogen, the so-called protein (which has never yet been obtained except as a product of living bodies) united with a large proportion of water, and forming the chief constituent of a substance which, in its primary unmodified state, is known as *protoplasm.*

2. Its *universal disintegration and waste by oxidation; and its concomitant reintegration by the intus-susception of new matter.*

A process of waste resulting from the decomposition of the molecules of the protoplasm, in virtue of which they break up into more highly oxidated products, which cease to form any part of the living body, is a constant concomitant of life. There is reason to believe that carbonic acid is always one of these waste products, while the others contain the remainder of the carbon, the nitrogen, the hydrogen, and the other elements which may enter into the composition of the protoplasm.

The new matter taken in to make good this constant loss is either a ready-formed protoplasmic material, supplied by some other living being, or it consists of the elements of protoplasm, united together in simpler combinations, which consequently have to be built up into protoplasm by the agency of the living matter itself. In either case, the addition of molecules to those which already existed takes place, not at the surface of the living mass, but by interposition between the existing molecules of the latter. If the processes of disintegration and of reconstruction which characterize life balance one another, the size of the mass of living matter remains stationary, while, if the reconstructive process is the more rapid, the living body *grows.* But the increase of size which constitutes growth is the result of a process of molecular intus-susception, and therefore differs altogether from the process of growth by accretion, which may be observed in crystals and is effected purely by the external addition of new matter—so that, in the well-known aphorism of Linnæus, the word "grow," as applied to stones, signifies a totally different process from what is called "growth" in plants and animals.

3. Its *tendency to undergo cyclical changes.*

In the ordinary course of nature, all living matter proceeds from pre-existing living matter, a portion of the latter being detached and acquiring an independent existence. The new form takes on the characters of that from which it arose; exhibits the same power of propagating itself by means of an offshoot; and, sooner or later, like its predecessor, ceases to live, and is resolved into more highly oxidated compounds of its elements.

Thus an individual living body is not only constantly changing its substance, but its size and form are undergoing continual modifications, the end of which is the death and decay of that individual; the continuation of the kind being secured by the detachment of portions which tend to run through the same cycle of forms as the parent. No forms of matter which are either not living, or have not been derived from living matter, exhibit these three properties, nor any approach to the remarkable phenomena defined under the second and third heads. But in addition to these distinctive characters, living matter has some

other peculiarities, the chief of which are the dependence of all its activities upon moisture and upon heat, within a limited range of temperature, and the fact that it usually possesses a certain structure, or organisation.

Life conditioned by moisture.

As has been said, a large proportion of water enters into the composition of all living matter; a certain amount of drying arrests vital activity, and the complete abstraction of this water is absolutely incompatible with either actual or potential life. But many of the simpler forms of life may undergo desiccation to such an extent as to arrest their vital manifestations and convert them into the semblance of not-living matter, and yet remain potentially alive. That is to say, on being duly moistened they return to life again. And this revivification may take place after months, or even years, of arrested life.

Life conditioned by temperature.

The properties of living matter are intimately related to temperature. Not only does exposure to heat sufficient to decompose protein matter destroy life, by demolishing the molecular structure upon which life depends; but all vital activity, all phenomena of nutritive growth, movement, and reproduction are possible only between certain limits of temperature. As the temperature approaches these limits the manifestations of life vanish, though they may be recovered by return to the normal conditions; but if it pass far beyond these limits, death takes place.

This much is clear; but it is not easy to say exactly what the limits of temperature are, as they appear to vary in part with the kind of living matter, and in part with the conditions of moisture which obtain along with the temperature. The conditions of life are so complex in the higher organisms, that the experimental investigation of this question can be satisfactorily attempted only in the lowest and simplest forms. It appears that, in the dry state, these are able to bear far greater extremes both of heat and cold than in the moist condition. Thus Pasteur found that the spores of fungi, when dry, could be exposed without destruction to a temperature of 120°–125° C. (248°–257 Fahr.), while the same spores, when moist, were all killed by exposure to 100° C. (212° Fahr.) On the other hand, Cagniard de la Tour found that dry yeast might be exposed to the extremely low temperature of solid carbonic acid (–60° C. or –76° Fahr.) without being killed. In the moist state he found that it might be frozen and cooled to –5 C. (23° Fahr.), but that it was killed by lower temperatures. However, it is very desirable that these experiments should be repeated, for Cohn's careful observations on *Bacteria* show that, though they fall into a state of torpidity, and, like yeast, lose all their powers of exciting fermentation at, or near, the freezing point of water, they are not killed by exposure for five hours to a temperature below –10° C. (14 Fahr.), and, for some time, sinking to 18° C. (–0 ·4 Fahr) Specimens of *Spirillum volutans*, which had been cooled to this extent, began to move about some little time after the ice containing them thawed. But Cohn remarks that *Euglenæ*, which were frozen along with them, were all killed and disorganised, and that the same fate had befallen the higher *Infusoria* and *Rotifera*, with the exception of some encysted *Vorticellæ*, in which the rhythmical movements of the contractile vesicle showed that life was preserved.

Thus it would appear that the resistance of living matter to cold depends greatly on the special form of that matter, and that the limit of the *Euglena*, simple organism as it is, is much higher than that of the *Bacterium*.

Considerations of this kind throw some light upon the apparently anomalous conditions under which many of the lower plants, such as *Protococcus* and the *Diatomaceæ*, and some of the lower animals, such as the *Radiolaria*, are observed to flourish. *Protococcus* has been found, not only on the snows of great heights in temperate latitudes, but covering extensive areas of ice and snow in the Arctic regions, where it must be exposed to extremely low temperatures,—in the latter case for many months together; while the Arctic and Antarctic seas swarm with *Diatomaceæ* and *Radiolaria*. It is on the *Diatomaceæ*, as Hooker has well shown, that all surface life in these regions ultimately depends; and their enormous multitudes prove that their rate of multiplication is adequate to meet the demands made upon them, and is not seriously impeded by the low temperature of the waters, never much above the freezing point, in which they habitually live.

The maximum limit of heat which living matter can resist is no less variable than its minimum limit. Kühne found that marine *Amœbæ* were killed when the temperature reached 35° C. (95° Fahr.), while this was not the case with fresh-water *Amœbæ*, which survived a heat of 5°, or even 10°, C. higher. And *Actinophrys Eichornii* was not killed until the temperature rose to 44° or 45° C. *Didymium serpula* is killed at 35° C.; while another *Myxomycete Æthalium septicum*, succumbs only at 40° C.

Cohn ("Untersuchungen über Bacterien," *Beiträge zur Biologie der Pflanzen* Heft 2, 1872), has given the results of a series of experiments conducted with the view of ascertaining the temperature at which *Bacteria* are destroyed, when living in a fluid of definite chemical composition, and free from all such complications as must arise from the inequalities of physical condition when solid particles other than the *Bacteria* co-exist with them. The fluid employed contained 0·1 gramme potassium phosphate, 0·1 gr. crystallised magnesium sulphate, 0·1 gr. tribasic calcium phosphate, and 0·2 gr. ammonium tartrate, dissolved in 20 cubic centimetres of distilled water. If to a certain quantity of this "normal fluid" a small proportion of water containing *Bacteria* was added, the multiplication of the *Bacteria* went on with rapidity, whether the mouth of the containing flask was open or hermetically closed. Hermetically-sealed flasks, containing portions of the normal fluid infected with *Bacteria*, were submerged in water heated to various temperatures, the flask being carefully shaken, without being raised out of the water, during its submergence.

The result was, that in those flasks which were thus subjected, for an hour, to a heat of 60°–62° C. (140°–143° Fahr.), the *Bacteria* underwent no development, and the fluid remained perfectly clear. On the other hand, in similar experiments in which the flasks were heated only to 40° or 50 C. (104°–122° Fahr.), the fluid became turbid, in consequence of the multiplication of the *Bacteria*, in the course of from two to three days.

Both in Kuhne's and in Cohn's experiments, which last have lately been confirmed and extended by Dr Roberts of Manchester, it was noted that long exposure to a lower temperature than that which brings about immediate destruction of life, produces the same effect as short exposure to the latter temperature. Thus, though all the *Bacteria* were killed, with certainty, in the normal fluid, by short exposure to temperatures at or above 60° C. (140° Fahr.), Cohn observed that, when a flask containing infected normal fluid was heated to 50°–52° C. (122°–125° Fahr.) for only an hour, the consequent multiplication of the *Bacteria* was manifested much earlier, than in one which had been exposed for two hours to the same temperature.

It appears to be very generally held that the simpler vegetable organisms are deprived of life at temperatures as high as 60° C. (140° Fahr.); but *Algæ* have been found living in hot springs at much higher temperatures, namely, from 168° to 208° Fahr., for which latter surprising fact we have the high authority of Descloiseaux. It is no ex-

planation of these phenomena, but only another mode of stating them, to say that these organisms have become "accustomed" to such temperatures. If this degree of heat were absolutely incompatible with the activity of living matter, the plants could no more resist it than they could become "accustomed" to being made red hot. Habit may modify subsidiary, but cannot affect fundamental, conditions.

Recent investigations point to the conclusion that the immediate cause of the arrest of vitality, in the first place, and of its destruction, in the second, is the coagulation of certain substances in the protoplasm, and that the latter contains various coagulable matters, which solidify at different temperatures. And it remains to be seen, how far the death of any form of living matter, at a given temperature, depends on the destruction of its fundamental substance at that heat, and how far death is brought about by the coagulation of merely accessory compounds.

Life and organization.

It may be safely said of all those living things which are large enough to enable us to trust the evidence of microscopes, that they are heterogeneous optically, and that their different parts, and especially the surface layer, as contrasted with the interior, differ physically and chemically; while, in most living things, mere heterogeneity is exchanged for a definite structure, whereby the body is distinguished into visibly different parts, which possess different powers or functions. Living things which present this visible structure are said to be *organized;* and so widely does organization obtain among living beings, that *organized* and *living* are not unfrequently used as if they were terms of co-extensive applicability. This, however, is not exactly accurate, if it be thereby implied that all living things have a visible organization, as there are numerous forms of living matter of which it cannot properly be said that they possess either a definite structure or permanently specialized organs: though, doubtless, the simplest particle of living matter must possess a highly complex molecular structure, which is far beyond the reach of vision.

The broad distinctions which, as a matter of fact, exist between every known form of living substance and every other component of the material world, justify the separation of the biological sciences from all others. But it must not be supposed that the differences between living and not-living matter are such as to justify the assumption that the forces at work in the one are different from those which are to be met with in the other. Considered apart from the phenomena of consciousness, the phenomena of life are all dependent upon the working of the same physical and chemical forces as those which are active in the rest of the world. It may be convenient to use the terms "vitality" and "vital force" to denote the causes of certain great groups of natural operations, as we employ the names of "electricity" and "electrical force" to denote others; but it ceases to be proper to do so, if such a name implies the absurd assumption that "electricity" and 'vitality" are entities playing the part of efficient causes of electrical or vital phenomena. A mass of living protoplasm is simply a molecular machine of great complexity, the total results of the working of which, or its vital phenomena, depend,—on the one hand, upon its construction, and, on the other, upon the energy supplied to it; and to speak of "vitality" as anything but the name of a series of operations is as if one should talk of the "horology" of a clock.

Classification of the phenomena of life.

Living matter, or protoplasm and the products of its metamorphosis, may be regarded under four aspects:—

(1.) It has a certain external and internal form, the latter being more usually called structure;

(2.) It occupies a certain position in space and in time;

(3.) It is the subject of the operation of certain forces in virtue of which it undergoes internal changes, modifies external objects, and is modified by them; and

(4.) Its form, place, and powers are the effects of certain causes.

In correspondence with these four aspects of its subject, biology is divisible into four chief subdivisions—I. MORPHOLOGY · II. DISTRIBUTION; III. PHYSIOLOGY; IV ÆTIOLOGY.

I. MORPHOLOGY.

So far as living beings have a form and structure, they fall within the province of *Anatomy* and *Histology*, the latter being merely a name for that ultimate optical analysis of living structure which can be carried out only by the aid of the microscope.

And, in so far as the form and structure of any living being are not constant during the whole of its existence, but undergo a series of changes from the commencement of that existence to its end, living beings have a *Development.* The history of development is an account of the anatomy of a living being at the successive periods of its existence, and of the manner in which one anatomical stage passes into the next.

Finally, the systematic statement and generalization of the facts of Morphology, in such a manner as to arrange living beings in groups according to their degrees of likeness, is *Taxonomy.*

The study of Anatomy and Development has brought to light certain generalizations of wide applicability and great importance.

Most plants and animals are aggregates of cells.

1. It has been said that the great majority of living beings present a very definite structure. Unassisted vision and ordinary dissection suffice to separate the body of any of the higher animals, or plants, into fabrics of different sorts, which always present the same general arrangement in the same organism, but are combined in different ways in different organisms. The discrimination of these comparatively few fabrics, or *tissues*, of which organisms are composed, was the first step towards that ultimate analysis of visible structure which has become possible only by the recent perfection of microscopes and of methods of preparation.

Histology, which embodies the results of this analysis, shows that every tissue of a plant is composed of more or less modified structural elements, each of which is termed a *cell;* which cell, in its simplest condition, is merely a spheroidal mass of protoplasm, surrounded by a coat or sac —the *cell-wall*—which contains cellulose. In the various tissues, these cells may undergo innumerable modifications of form—the protoplasm may become differentiated into a nucleus with its nucleolus, a primordial utricle, and a cavity filled with a watery fluid, and the cell-wall may be variously altered in composition or in structure, or may coalesce with others But, however extensive these changes may be, the fact that the tissues are made up of morphologically distinct units—the cells—remains patent. And, if any doubt could exist on the subject, it would be removed by the study of development, which proves that every plant commences its existence as a simple cell, identical in its fundamental characters with the less modified of those cells of which the whole body is composed.

But it is not necessary to the morphological unit of the plant that it should be always provided with a cell-wall. Certain plants, such as *Protococcus*, spend longer or shorter periods of their existence in the condition of a mere spheroid of protoplasm, devoid of any cellulose wall, while, at other times, the protoplasmic body becomes enclosed within a cell-wall, fabricated by its superficial layer.

Therefore, just as the nucleus, the primordial utricle, and the central fluid are no essential constituents of the

morphological unit of the plant, but represent results of its metamorphosis, so the cell-wall is equally unessential; and either the term "cell" must acquire a merely technical significance as the equivalent of morphological unit, or some new term must be invented to describe the latter. On the whole, it is probably least inconvenient to modify the sense of the word "cell."

The histological analysis of animal tissues has led to results and to difficulties of terminology of precisely the same character. In the higher animals, however, the modifications which the cells undergo are so extensive, that the fact that the tissues are, as in plants, resolvable into an aggregation of morphological units, could never have been established without the aid of the study of development, which proves that the animal, no less than the plant, commences its existence as a simple cell, fundamentally identical with the less modified cells which are found in the tissues of the adult.

Though the nucleus is very constant among animal cells, it is not universally present; and among the lowest forms of animal life, the protoplasmic mass which represents the morphological unit may be, as in the lowest plants, devoid of a nucleus. In the animal, the cell-wall never has the character of a shut sac containing cellulose; and it is not a little difficult, in many cases, to say how much of the so-called "cell-wall" of the animal cell answers to the "primordial utricle" and how much to the proper "cellulose cell-wall" of the vegetable cell. But it is certain that in the animal, as in the plant, neither cell-wall nor nucleus are essential constituents of the cell, inasmuch as bodies which are unquestionably the equivalents of cells—true morphological units—are mere masses of protoplasm, devoid alike of cell-wall and nucleus.

For the whole living world, then, it results:—that the morphological unit—the primary and fundamental form of life—is merely an individual mass of protoplasm, in which no further structure is discernible; that independent living forms may present but little advance on this structure; and that all the higher forms of life are aggregates of such morphological units or cells, variously modified.

Moreover, all that is at present known tends to the conclusion, that, in the complex aggregates of such units of which all the higher animals and plants consist, no cell has arisen otherwise than by becoming separated from the protoplasm of a pre-existing cell; whence the aphorism "*Omnis cellula e cellula.*"

It may further be added, as a general truth applicable to nucleated cells, that the nucleus rarely undergoes any considerable modification, the structures characteristic of the tissues being formed at the expense of the more superficial protoplasm of the cells; and that, when nucleated cells divide, the division of the nucleus, as a rule, precedes that of the whole cell.

Development a process of differentiation.

2. In the course of its development every cell proceeds from a condition in which it closely resembles every other cell, through a series of stages of gradually increasing divergence, until it reaches that condition in which it presents the characteristic features of the elements of a special tissue. The development of the cell is therefore a gradual progress from the general to the special state.

The like holds good of the development of the body as a whole. However complicated one of the higher animals or plants may be, it begins its separate existence under the form of a nucleated cell. This, by division, becomes converted into an aggregate of nucleated cells: the parts of this aggregate, following different laws of growth and multiplication, give rise to the rudiments of the organs; and the parts of these rudiments again take on those modes of growth and multiplication and metamorphosis which are needful to convert the rudiment into the perfect structure. The development of the organism as a whole, therefore, repeats in principle the development of the cell. It is a progress from a general to a special form, resulting from the gradual differentiation of the primitively similar morphological units of which the body is composed.

Moreover, when the stages of development of two animals are compared, the number of these stages which are similar to one another is, as a general rule, proportional to the closeness of the resemblance of the adult forms; whence it follows that the more closely any two animals are allied in adult structure, the later are their embryonic conditions distinguishable. And this general rule holds for plants no less than for animals.

The broad principle, that the form in which the more complex living things commence their development is always the same, was first expressed by Harvey in his famous aphorism, "*Omne vivum ex ovo,*" which was intended simply as a morphological generalization, and in no wise implied the rejection of spontaneous generation, as it is commonly supposed to do. Moreover, Harvey's study of the development of the chick led him to promulgate that theory of "epigenesis," in which the doctrine that development is a progress from the general to the special is implicitly contained.

Caspar F. Wolff furnished further, and indeed conclusive, proof of the truth of the theory of epigenesis; but, unfortunately, the authority of Haller and the speculations of Bonnet led science astray, and it was reserved for Von Baer to put the nature of the process of development in its true light, and to formulate it in his famous law.

3. Development, then, is a process of differentiation by which the primitively similar parts of the living body become more and more unlike one another.

Modes of differentiation.

This process of differentiation may be effected in several ways.

(1.) The protoplasm of the germ may not undergo division and conversion into a cell aggregate; but various parts of its outer and inner substance may be metamorphosed directly into those physically and chemically different materials which constitute the body of the adult. This occurs in such animals as the *Infusoria*, and in such plants as the unicellular *Algæ*.

(2.) The germ may undergo division, and be converted into an aggregate of cells, which cells give rise to the tissues by undergoing a metamorphosis of the same kind as that to which the whole body is subjected in the preceding case.

The body, formed in either of these ways, may, as a whole, undergo metamorphosis by differentiation of its parts, and the differentiation may take place without reference to any axis of symmetry, or it may have reference to such an axis. In the latter case, the parts of the body which become distinguishable may correspond on the two sides of the axis (bilateral symmetry), or may correspond along several lines parallel with the axis (radial symmetry).

The bilateral or radial symmetry of the body may be further complicated by its segmentation, or separation by divisions transverse to the axis, into parts, each of which corresponds with its predecessor or successor in the series.

In the segmented body, the segments may or may not give rise to symmetrically or asymmetrically disposed processes, which are *appendages*, using that word in its most general sense.

And the highest degree of complication of structure, in both animals and plants, is attained by the body when it becomes divided into segments provided with appendages; when the segments not only become very different from one another, but some coalesce and lose their primitive distinctness; and when the appendages and the segments into

which they are subdivided similarly become differentiated and coalesce.

It is in virtue of such processes that the flowers of plants, and the heads and limbs of the *Arthropoda* and of the *Vertebrata*, among animals, attain their extraordinary diversity and complication of structure. A flower-bud is a segmented body or axis, with a certain number of whorls of appendages; and the perfect flower is the result of the gradual differentiation and confluence of these primitively similar segments and their appendages. The head of an insect or of a crustacean is, in like manner, composed of a number of segments, each with its pair of appendages, which by differentiation and confluence are converted into the feelers and variously modified oral appendages of the adult.

In some complex organisms, the process of differentiation, by which they pass from the condition of aggregated embryo cells to the adult, can be traced back to the laws of growth of the two or more cells into which the embryo cell is divided, each of these cells giving rise to a particular portion of the adult organism. Thus the fertilized embryo cell in the archegonium of a fern divides into four cells, one of which gives rise to the rhizome of the young fern, another to its first rootlet, while the other two are converted into a placenta-like mass which remains embedded in the prothallus.

The structure of the stem of *Chara* depends upon the different properties of the cells, which are successively derived by transverse division from the apical cell. An *inter-nodal* cell, which elongates greatly, and does not divide, is succeeded by a *nodal* cell, which elongates but little, and becomes greatly subdivided; this by another inter-nodal cell, and so on in regular alternation. In the same way the structure of the stem, in all the higher plants, depends upon the laws which govern the manner of division and of metamorphosis of the apical cells, and of their continuation in the *cambium* layer.

In all animals which consist of cell-aggregates, the cells of which the embryo is at first composed arrange themselves by the splitting, or by a process of invagination, of the blastoderm into two layers, the *epiblast* and the *hypoblast*, between which a third intermediate layer, the *mesoblast*, appears, and each layer gives rise to a definite group of organs in the adult. Thus, in the *Vertebrata*, the epiblast gives rise to the cerebro-spinal axis, and to the epidermis and its derivatives; the hypoblast, to the epithelium of the alimentary canal and its derivatives; and the mesoblast, to all the intermediate structures. The tendency of recent inquiry is to prove that the several layers of the germ evolve analogous organs in invertebrate animals, and to indicate the possibility of tracing the several germ layers back to the blastomeres of the yelk, from the subdivision of which they proceed.

Taxonomy. It is conceivable that all the forms of life should have presented about the same differentiation of structure, and should have differed from one another by superficial characters, each form passing by insensible gradations into those most like it. In this case Taxonomy, or the classification of morphological facts, would have had to confine itself to the formation of a serial arrangement representing the serial gradation of these forms in nature.

It is conceivable, again, that living beings should have differed as widely in structure as they actually do, but that the interval between any two extreme forms should have been filled up by an unbroken series of gradations; in which case, again, classification could only effect the formation of series—the strict definition of groups would be as impossible as in the former case.

As a matter of fact, living beings differ enormously, not only in differentiation of structure, but in the modes in which that differentiation is brought about; and the intervals between extreme forms are not filled up in the existing world by complete series of gradations. Hence it arises that living beings are, to a great extent, susceptible of classification into groups, the members of each group resembling one another, and differing from all the rest, by certain definite peculiarities.

No two living beings are exactly alike, but it is a matter of observation that, among the endless diversities of living things, some constantly resemble one another so closely that it is impossible to draw any line of demarcation between them, while they differ only in such characters as are associated with sex. Such as thus closely resemble one another constitute a *morphological species*; while different morphological species are defined by constant characters which are not merely sexual.

The comparison of these lowest groups, or morphological species, with one another, shows that more or fewer of them possess some character or characters in common—some feature in which they resemble one another and differ from all other species—and the group or higher order thus formed is a *genus*. The generic groups thus constituted are susceptible of being arranged in a similar manner into groups of successively higher order, which are known as *families*, *orders*, *classes*, and the like.

The method pursued in the classification of living forms is, in fact, exactly the same as that followed by the maker of an index in working out the heads indexed. In an alphabetical arrangement, the classification may be truly termed a morphological one, the object being to put into close relation all those leading words which resemble one another in the arrangement of their letters, that is, in their form, and to keep apart those which differ in structure. Headings which begin with the same word, but differ otherwise, might be compared to genera with their species; the groups of words with the same first two syllables to families; those with identical first syllables to orders; and those with the same initial letter to classes. But there is this difference between the index and the Taxonomic arrangement of living forms, that in the former there is none but an arbitrary relation between the various classes, while in the latter the classes are similarly capable of co-ordination into larger and larger groups, until all are comprehended under the common definition of living beings.

Artificial and natural classification. The differences between "artificial" and "natural" classifications are differences in degree, and not in kind. In each case the classification depends upon likeness; but in an artificial classification some prominent and easily observed feature is taken as the mark of resemblance or dissemblance; while, in a natural classification, the things classified are arranged according to the totality of their morphological resemblances, and the features which are taken as the marks of groups are those which have been ascertained by observation to be the indications of many likenesses or unlikenesses. And thus a natural classification is a great deal more than a mere index. It is a statement of the marks of similarity of organization; of the kinds of structure which, as a matter of experience, are found universally associated together; and, as such, it furnishes the whole foundation for those indications by which conclusions as to the nature of the whole of an animal are drawn from a knowledge of some part of it.

When a palæontologist argues from the characters of a bone or of a shell to the nature of the animal to which that bone or shell belonged, he is guided by the empirical morphological laws established by wide observation, that such a kind of bone or shell is associated with such and such structural features in the rest of the body, and no

others. And it is these empirical laws which are embodied and expressed in a natural classification.

II. Distribution.

Geographical distribution.

Living beings occupy certain portions of the surface of the earth, inhabiting either the dry land or the fresh or salt waters, or being competent to maintain their existence in either. In any given locality, it is found that those different media are inhabited by different kinds of living beings; and that the same medium, at different heights in the air and at different depths in the water, has different living inhabitants.

Moreover, the living populations of localities which differ considerably in latitude, and hence in climate, always present considerable differences. But the converse proposition is not true; that is to say, localities which differ in longitude, even if they resemble one another in climate, often have very dissimilar *faunæ* and *floræ*.

It has been discovered by careful comparison of local faunæ and floræ that certain areas of the earth's surface are inhabited by groups of animals and plants which are not found elsewhere, and which thus characterize each of these areas. Such areas are termed *Provinces of Distribution.* There is no parity between these provinces in extent, nor in the physical configuration of their boundaries; and, in reference to existing conditions, nothing can appear to be more arbitrary and capricious than the distribution of living beings.

Geological distribution.

The study of distribution is not confined to the present order of nature; but, by the help of geology, the naturalist is enabled to obtain clear, though too fragmentary, evidence of the characters of the faunæ and floræ of antecedent epochs. The remains of organisms which are contained in the stratified rocks prove that, in any given part of the earth's surface, the living population of earlier epochs was different from that which now exists in the locality; and that, on the whole, the difference becomes greater the farther we go back in time. The organic remains which are found in the later Cainozoic deposits of any district are always closely allied to those now found in the province of distribution in which that locality is included; while in the older Cainozoic, the Mesozoic, and the Palæozoic strata, the fossils may be similar to creatures at present living in some other province, or may be altogether unlike any which now exist.

Continuity of succession of forms of life in time.

In any given locality, the succession of living forms may appear to be interrupted by numerous breaks—the associated species in each fossiliferous bed being quite distinct from those above and those below them. But the tendency of all palæontological investigation is to show that these breaks are only apparent, and arise from the incompleteness of the series of remains which happens to have been preserved in any given locality. As the area over which accurate geological investigations have been carried on extends, and as the fossiliferous rocks found in one locality fill up the gaps left in another, so do the abrupt demarcations between the faunæ and floræ of successive epochs disappear—a certain proportion of the genera and species of every period, great or small, being found to be continued for a longer or shorter time into the next succeeding period. It is evident, in fact, that the changes in the living population of the globe which have taken place during its history, have been effected, not by the sudden replacement of one set of living beings by another, but by a process of slow and gradual introduction of new species, accompanied by the extinction of the older forms.

It is a remarkable circumstance, that in all parts of the globe in which fossiliferous rocks have yet been examined, the successive terms of the series of living forms which have thus succeeded one another are analogous. The life of the Mesozoic epoch is everywhere characterized by the abundance of some groups of species of which no trace is to be found in either earlier or later formations; and the like is true of the Palæozoic epoch. Hence it follows, not only that there has been a succession of species, but that the general nature of that succession has been the same all over the globe; and it is on this ground that fossils are so important to the geologist as marks of the relative age of rocks.

The determination of the morphological relations of the species which have thus succeeded one another is a problem of profound importance and difficulty, the solution of which, however, is already clearly indicated. For, in several cases, it is possible to show that, in the same geographical area, a form A, which existed during a certain geological epoch, has been replaced by another form B, at a later period; and that this form B has been replaced, still later, by a third form C. When these forms, A, B, and C, are compared together they are found to be organized upon the same plan, and to be very similar even in most of the details of their structure; but B differs from A by a slight modification of some of its parts, which modification is carried to a still greater extent in C.

Progressive specialization of forms of life in time.

In other words, A, B, and C differ from one another in the same fashion as the earlier and later stages of the embryo of the same animals differ; and in successive epochs we have the group presenting that progressive specialization which characterises the development of the individual. Clear evidence that this progressive specialization of structure has actually occurred has as yet been obtained in only a few cases (*e.g., Equidæ, Crocodilia*), and these are confined to the highest and most complicated forms of life; while it is demonstrable that, even as reckoned by geological time, the process must have been exceedingly slow.

Among the lower and less complicated forms the evidence of progressive modifications, furnished by comparison of the oldest with the latest forms, is slight, or absent; and some of these have certainly persisted, with very little change, from extremely ancient times to the present day. It is as important to recognize the fact that certain forms of life have thus persisted, as it is to admit that others have undergone progressive modification.

Geographical distribution of ancient faunæ and floræ.

It has been said that the successive terms in the series of living forms are analogous in all parts of the globe. But the species which constitute the corresponding or *homotaxic* terms in the series, in different localities, are not identical. And, though the imperfection of our knowledge at present precludes positive assertion, there is every reason to believe that geographical provinces have existed throughout the period during which organic remains furnish us with evidence of the existence of life. The wide distribution of certain Palæozic forms does not militate against this view; for the recent investigations into the nature of the deep-sea fauna have shown that numerous *Crustacea, Echinodermata,* and other invertebrate animals, have as wide a distribution now as their analogues possessed in the Silurian epoch.

III. Physiology.

Living beings as machines in action.

Thus far living beings have been regarded merely as definite forms of matter, and Biology has presented no considerations of a different order from those which meet the student of Mineralogy. But living things are not only natural bodies, having a definite form and mode of structure, growth, and development. They are machines in action; and, under this aspect, the phenomena which they present have no parallel in the mineral world.

The actions of living matter are termed its *functions;* and these functions, varied as they are, may be reduced to

Classification of functions. three categories. They are either—(1), functions which affect the material composition of the body, and determine its mass, which is the balance of the processes of waste on the one hand and those of assimilation on the other. Or (2), they are functions which subserve the process of reproduction, which is essentially the detachment of a part endowed with the power of developing into an independent whole. Or (3), they are functions in virtue of which one part of the body is able to exert a direct influence on another, and the body, by its parts or as a whole, becomes a source of molar motion. The first may be termed *sustentative*, the second *generative*, and the third *correlative* functions.

Of these three classes of functions the first two only can be said to be invariably present in living beings, all of which are nourished, grow, and multiply. But there are some forms of life, such as many *Fungi*, which are not known to possess any powers of changing their form; in which the protoplasm exhibits no movements, and reacts upon no stimulus; and in which any influence which the different parts of the body exert upon one another must be transmitted indirectly from molecule to molecule of the common mass. In most of the lowest plants, however, and in all animals yet known, the body either constantly or temporarily changes its form, either with or without the application of a special stimulus, and thereby modifies the relations of its parts to one another, and of the whole to surrounding bodies; while, in all the higher animals, the different parts of the body are able to affect, and be affected by, one another, by means of a special tissue, termed *nerve*. Molar motion is effected on a large scale by means of another special tissue, *muscle;* and the organism is brought into relation with surrounding bodies by means of a third kind of special tissue—that of the *sensory organs*—by means of which the forces exerted by surrounding bodies are transmuted into affections of nerve.

In the lowest forms of life, the functions which have been enumerated are seen in their simplest forms, and they are exerted indifferently, or nearly so, by all parts of the protoplasmic body; and the like is true of the functions of the body of even the highest organisms, so long as they are in the condition of the nucleated cell, which constitutes the starting point of their development. But the first process in that development is the division of the germ into a number of morphological units or blastomeres, which, eventually, give rise to cells; and as each of these possesses the same physiological functions as the germ itself, it follows that each morphological unit is also a physiological unit, and the multicellular mass is strictly a compound organism, made up of a multitude of physiologically

Physiological units. independent cells. The physiological activities manifested by the complex whole represent the sum, or rather the resultant, of the separate and independent physiological activities resident in each of the simpler constituents of that whole.

The morphological changes which the cells undergo in the course of the further development of the organism do not affect their individuality; and, notwithstanding the modification and confluence of its constituent cells, the adult organism, however complex, is still an aggregate of morphological units. Nor is it less an aggregate of physiological units, each of which retains its fundamental independence, though that independence becomes restricted in various ways.

Each cell, or that element of a tissue which proceeds from the modification of a cell, must needs retain its sustentative functions so long as it grows or maintains a condition of equilibrium; but the most completely metamorphosed cells show no trace of the generative function, and many exhibit no correlative functions. On the other hand, those cells of the adult organism which are the unmetamorphosed derivatives of the germ, exhibit all the primary functions, not only nourishing themselves and growing, but multiplying, and frequently showing more or less marked movements.

Organs are parts of the body which perform particular functions. In strictness, perhaps, it is not quite right to speak of organs of sustentation or generation, each of these functions being necessarily performed by the morphological unit which is nourished or reproduced. What are called the organs of these functions are the apparatuses by which certain operations, subsidiary to sustentation and generation, are carried on.

Thus, in the case of the sustentative functions, all those organs may be said to contribute to this function which are concerned in bringing nutriment within reach of the ultimate cells, or in removing waste matter from them; while in the case of the generative function, all those organs contribute to the function which produce the cells from which germs are given off; or help in the evacuation, or fertilization, or development of these germs.

On the other hand, the correlative functions, so long as they are exerted by a simple undifferentiated morphological unit or cell, are of the simplest character, consisting of those modifications of position which can be effected by mere changes in the form or arrangement of the parts of the protoplasm, or of those prolongations of the protoplasm which are called pseudopodia or cilia. But, in the higher animals and plants, the movements of the organism and of its parts are brought about by the change of the form of certain tissues, the property of which is to shorten in one direction when exposed to certain stimuli. Such tissues are termed *contractile;* and, in their most fully developed condition, *muscular*. The stimulus by which this contraction is naturally brought about is a molecular change, either in the substance of the contractile tissue itself, or in some other part of the body; in which latter case, the motion which is set up in that part of the body must be propagated to the contractile tissue through the intermediate substance of the body. In plants there seems to be no question that parts which retain a hardly modified cellular structure may serve as channels for the transmission of this molecular motion; whether the same is true of animals is not certain. But, in all the more complex animals, a peculiar fibrous tissue—*nerve*—serves as the agent by which contractile tissue is affected by changes occurring elsewhere, and by which contractions thus initiated are co-ordinated and brought into harmonious combination. While the sustentative functions in the higher forms of life are still, as in the lower, fundamentally dependent upon the powers inherent in all the physiological units which make up the body, the correlative functions are, in the former, deputed to two sets of specially modified units, which constitute the muscular and the nervous tissues.

Division of physiological labour. When the different forms of life are compared together as physiological machines, they are found to differ as machines of human construction do. In the lower forms, the mechanism, though perfectly well adapted to do the work for which it is required, is rough, simple, and weak; while, in the higher, it is finished, complicated, and powerful. Considered as machines, there is the same sort of difference between a polype and a horse as there is between a distaff and a spinning-jenny. In the progress from the lower to the higher organism, there is a gradual differentiation of organs and of functions. Each function is separated into many parts, which are severally entrusted to distinct organs. To use the striking phrase of Milne-Edwards, in passing from low to high organisms, there is a division of physiological labour. And exactly the same process is observable in the development of any of the higher organ-

isms; so that, physiologically, as well as morphologically, development is a progress from the general to the special.

Thus far, the physiological activities of living matter have been considered in themselves, and without reference to anything that may affect them in the world outside the living body. But living matter acts on, and is powerfully affected by, the bodies which surround it; and the study of the influence of the "conditions of existence" thus determined constitutes a most important part of Physiology.

Conditions of existence.

The sustentative functions, for example, can only be exerted under certain conditions of temperature, pressure, and light, in certain media, and with supplies of particular kinds of nutritive matter; the sufficiency of which supplies again, is greatly influenced by the competition of other organisms, which, striving to satisfy the same needs, give rise to the passive "struggle for existence." The exercise of the correlative functions is influenced by similar conditions, and by the direct conflict with other organisms, which constitutes the active struggle for existence. And, finally, the generative functions are subject to extensive modifications, dependent partly upon what are commonly called external conditions, and partly upon wholly unknown agencies.

Reproduction by fission and gemmation: agamogenesis.

In the lowest forms of life the only mode of generation at present known is the division of the body into two or more parts, each of which then grows to the size and assumes the form of its parent, and repeats the process of multiplication. This method of multiplication by *fission* is properly called generation, because the parts which are separated are severally competent to give rise to individual organisms of the same nature as that from which they arose.

In many of the lowest organisms the process is modified so far that, instead of the parent dividing into two equal parts, only a small portion of its substance is detached, as a bud which develops into the likeness of its parent. This is generation by *gemmation*. Generation by fission and by gemmation are not confined to the simplest forms of life, however. On the contrary, both modes of multiplication are common not only among plants, but among animals of considerable complexity.

The multiplication of flowering plants by bulbs, that of annelids by fission, and that of polypes by budding, are well-known examples of these modes of reproduction. In all these cases, the bud or the segment consists of a multitude of more or less metamorphosed cells. But, in other instances, a single cell detached from a mass of such undifferentiated cells contained in the parental organism is the foundation of the new organism, and it is hard to say whether such a detached cell may be more fitly called a bud or a segment—whether the process is more akin to fission or to gemmation.

In all these cases the development of the new being from the detached germ takes place without the influence of other living matter. Common as the process is in plants and in the lower animals, it becomes rare among the higher animals. In these, the reproduction of the whole organism from a part, in the way indicated above, ceases. At most, we find that the cells at the end of an amputated portion of the organism are capable of reproducing the lost part; and, in the very highest animals, even this power vanishes in the adult; and, in most parts of the body, though the undifferentiated cells are capable of multiplication, their progeny grow, not into whole organisms like that of which they form a part, but into elements of the tissues.

Throughout almost the whole series of living beings, however, we find concurrently with the process of *agamogenesis*, or asexual generation, another method of generation, in which the development of the germ into an organism resembling the parent depends on an influence exerted by living matter different from the germ. This is *gamogenesis*, or sexual generation. Looking at the facts broadly, and without reference to many exceptions in detail, it may be said that there is an inverse relation between agamogenetic and gamogenetic reproduction. In the lowest organisms gamogenesis has not yet been observed, while in the highest agamogenesis is absent. In many of the lower forms of life agamogenesis is the common and predominant mode of reproduction, while gamogenesis is exceptional; on the contrary, in many of the higher, while gamogenesis is the rule, agamogenesis takes place exceptionally. In its simplest condition, which is termed "*conjugation*," sexual generation consists in the coalescence of two similar masses of protoplasmic matter, derived from different parts of the same organism, or from two organisms of the same species, and the single mass which results from the fusion develops into a new organism.

Sexual reproduction.

In the majority of cases, however, there is a marked morphological difference between the two factors in the process, and then one is called the male, and the other the female element. The female element is relatively large, and undergoes but little change of form. In all the higher plants and animals it is a nucleated cell, to which a greater or less amount of nutritive material, constituting the food-yelk, may be added.

The male element, on the other hand, is relatively small. It may be conveyed to the female element by an outgrowth of the wall of its cell, which is short in many *Algæ* and *Fungi*, but becomes an immensely elongated tubular filament, in the case of the pollen cell of flowering plants. But, more commonly, the protoplasm of the male cells becomes converted into rods or filaments, which usually are in active vibratile movement, and sometimes are propelled by numerous cilia. Occasionally, however, as in many *Nematoidea* and *Arthropoda*, they are devoid of mobility.

The manner in which the contents of the pollen tube affect the embryo cell in flowering plants is unknown, as no perforations through which the contents of the pollen tube may pass, so as actually to mix with the substance of the embryo cell, have been discovered; and there is the same difficulty with respect to the conjugative processes of some of the *Cryptogamia*. But in the great majority of plants, and in all animals, there can be no doubt that the substance of the male element actually mixes with that of the female, so that in all these cases the sexual process remains one of conjugation; and impregnation is the physical admixture of protoplasmic matter derived from two sources, which may be either different parts of the same organism, or different organisms.

Immediate consequences of fecundation.

The effect of impregnation appears in all cases to be that the impregnated protoplasm tends to divide into portions (*blastomeres*), which may remain united as a single cell-aggregate, or some or all of which may become separate organisms. A larger or shorter period of rest, in many cases, intervenes between the act of impregnation and the commencement of the process of division.

As a general rule, the female cell which directly receives the influence of the male is that which undergoes division and eventual development into independent germs; but there are some plants, such as the *Florideæ*, in which this is not the case. In these the protoplasmic body of the trichogyne, which unites with the molecular spermatozoids, does not undergo division itself, but transmits some influence to adjacent cells, in virtue of which they become subdivided into independent germs or spores.

There is still much obscurity respecting the reproductive processes of the *Infusoria*; but, in the *Vorticellidæ*, it would appear that conjugation merely determines a condition of

the whole organism, which gives rise to the division of the endoplast or so-called nucleus, by which germs are thrown off; and if this be the case, the process would have some analogy to what takes place in the *Florideæ*.

On the other hand, the process of conjugation by which two distinct *Diporpæ* combine into that extraordinary double organism, the *Diplozoon paradoxum*, does not directly give rise to germs, but determines the development of the sexual organs in each of the conjugated individuals; and the same process takes place in a large number of the *Infusoria*, if what are supposed to be male sexual elements in them are really such.

The process of impregnation in the *Florideæ* is remarkably interesting, from its bearing upon the changes which fecundation is known to produce upon parts of the parental organism other than the ovum, even in the highest animals and plants.

The nature of the influence exerted by the male element upon the female is wholly unknown. No morphological distinction can be drawn between those cells which are capable of reproducing the whole organism without impregnation, and those which need it, as is obvious from what happens in insects, where eggs which ordinarily require impregnation, exceptionally, as in many moths, or regularly, as in the case of the drones among bees, develop without impregnation. Even in the higher animals, such as the fowl, the earlier stages of division of the germ may take place without impregnation.

In fact, generation may be regarded as a particular case of cell multiplication, and impregnation simply as one of the many conditions which may determine or affect that process. In the lowest organisms, the simple protoplasmic mass divides, and each part retains all the physiological properties of the whole, and consequently constitutes a germ whence the whole body can be reproduced. In more advanced organisms, each of the multitude of cells into which the embryo cell is converted at first, probably retains all, or nearly all, the physiological capabilities of the whole, and is capable of serving as a reproductive germ; but as division goes on, and many of the cells which result from division acquire special morphological and physiological properties, it seems not improbable that they, in proportion, lose their more general characters. In proportion, for example, as the tendency of a given cell to become a muscle cell or a cartilage cell is more marked and definite, it is readily conceivable that its primitive capacity to reproduce the whole organism should be reduced, though it might not be altogether abolished. If this view is well based, the power of reproducing the whole organism would be limited to those cells which had acquired no special tendencies, and consequently had retained all the powers of the primitive cell in which the organism commenced its existence. The more extensively diffused such cells were, the more generally might multiplication by budding or fission take place; the more localized, the more limited would be the parts of the organism in which such a process would take place. And even where such cells occurred, their development or non-development might be connected with conditions of nutrition. It depends on the nutriment supplied to the female larva of a bee whether it shall become a neuter or a sexually perfect female; and the sexual perfection of a large proportion of the internal parasites is similarly dependent upon their food, and perhaps on other conditions, such as the temperature of the medium in which they live. Thus the gradual disappearance of agamogenesis in the higher animals would be related with that increasing specialization of function which is their essential characteristic; and when it ceases to occur altogether, it may be supposed that no cells are left which retain unmodified the powers of the primitive embryo cell. The organism is like a society in which every one is so engrossed by his special business that he has neither time nor inclination to marry.

Even the female elements in the highest organisms, little as they differ to all appearance from undifferentiated cells, and though they are directly derived from epithelial cells which have undergone very little modification from the condition of blastomeres, are incapable of full development unless they are subjected to the influence of the male element, which may, as Caspar Wolff suggested, be compared to a kind of nutriment. But it is a living nutriment, in some respects comparable to that which would be supplied to an animal kept alive by transfusion, and its molecules transfer to the impregnated embryo cell all the special characters of the organism to which it belonged.

Hereditary transmission. The tendency of the germ to reproduce the characters of its immediate parents, combined, in the case of sexual generation, with the tendency to reproduce the characters of the male, is the source of the singular phenomena of hereditary transmission. No structural modification is so slight, and no functional peculiarity is so insignificant in either parent that it may not make its appearance in the offspring. But the transmission of parental peculiarities depends greatly upon the manner in which they have been acquired. Such as have arisen naturally, and have been hereditary through many antecedent generations, tend to appear in the progeny with great force; while artificial modifications, such, for example, as result from mutilation, are rarely, if ever, transmitted. Circumcision through innumerable ancestral generations does not appear to have reduced that rite to a mere formality, as it should have done, if the abbreviated prepuce had become hereditary in the descendants of Abraham; while modern lambs are born with long tails, notwithstanding the long-continued practice of cutting those of every generation short. And it remains to be seen whether the supposed hereditary transmission of the habit of retrieving among dogs is really what it seems at first sight to be; on the other side, Brown-Séquard's case of the transmission of artificially induced epilepsy in guinea-pigs is undoubtedly very weighty.

Variation. Although the germ always tends to reproduce, directly or indirectly, the organism from which it is derived, the result of its development differs somewhat from the parent. Usually the amount of variation is insignificant; but it may be considerable, as in the so-called "sports;" and such variations, whether useful or useless, may be transmitted with great tenacity to the offspring of the subjects of them.

The alternation of generations. In many plants and animals which multiply both asexually and sexually, there is no definite relation between the agamogenetic and the gamogenetic phenomena. The organism may multiply asexually before, or after, or concurrently with, the occurrence of sexual generation.

But in a great many of the lower organisms, both animal and vegetable, the organism (A) which results from the impregnated germ produces offspring only agamogenetically. It thus gives rise to a series of independent organisms (B, B, B, . . .), which are more or less different from A, and which sooner or later acquire generative organs. From their impregnated germs A is reproduced. The process thus described is what has been termed the "alternation of generations" under its simplest form,—for example, as it is exhibited by the *Salpæ*. In more complicated cases, the independent organisms which correspond with B may give rise agamogenetically to others (B_1), and these to others (B_2), and so on (*e.g.*, *Aphis*). But, however long the series, a final term appears which develops sexual organs, and reproduces A. The "alternation of generations" is, therefore, in strictness, an alternation of asexual with sexual generation, in which the products of the one process differ from those of the other.

The *Hydrozoa* offer a complete series of gradations between those cases in which the term B is represented by a free, self-nourishing organism (*e.g.*, *Cyanæa*), through those in which it is free but unable to feed itself (*Calycophoridæ*), to those in which the sexual elements are developed in bodies which resemble free zoöids, but are never detached, and are mere generative organs of the body on which they are developed (*Cordylophora*).

Individuality. In the last case, the "individual" is the total product of the development of the impregnated embryo, all the parts of which remain in material continuity with one another. The multiplication of mouths and stomachs in a *Cordylophora* no more makes it an aggregation of different individuals than the multiplication of segments and legs in a centipede converts that Arthropod into a compound animal. The *Cordylophora* is a differentiation of a whole into many parts, and the use of any terminology which implies that it results from the coalescence of many parts into a whole is to be deprecated.

In *Cordylophora* the generative organs are incapable of maintaining a separate existence; but in nearly allied *Hydrozoa* the unquestionable homologues of these organs become free zooids, in many cases capable of feeding and growing, and developing the sexual elements only after they have undergone considerable changes of form. Morphologically, the swarm of *Medusæ* thus set free from a Hydrozoon are as much organs of the latter, as the multitudinous pinnules of a *Comatula*, with their genital glands, are organs of the Echinoderm. Morphologically, therefore, the equivalent of the individual *Comatula* is the Hydrozoic stock + all the *Medusæ* which proceed from it.

No doubt it sounds paradoxical to speak of a million of *Aphides*, for example, as parts of one morphological individual; but beyond the momentary shock of the paradox no harm is done. On the other hand, if the asexual *Aphides* are held to be individuals, it follows, as a logical consequence, not only that all the polypes on a *Cordylophora* tree are "feeding individuals," and all the genital sacs "generative individuals," while the stem must be a "stump individual," but that the eyes and legs of a lobster are "ocular" and "locomotive individuals." And this conception is not only somewhat more paradoxical than the other, but suggests a conception of the origin of the complexity of animal structure which is wholly inconsistent with fact.

IV. Ætiology.

Causes of the phenomena of life. Morphology, Distribution, and Physiology investigate and determine the facts of Biology. Ætiology has for its object the ascertainment of the causes of these facts, and the explanation of biological phenomena, by showing that they constitute particular cases of general physical laws. It is hardly needful to say that ætiology, as thus conceived, is in its infancy, and that the seething controversies, to which the attempt to found this branch of science made in the *Origin of Species* has given rise, cannot be dealt with in the limits of this article. At most, the general nature of the problems to be evolved, and the course of inquiry needful for their solution, may be indicated.

In any investigation into the causes of the phenomena of life, the first question which arises is, whether we have any knowledge, and if so, what knowledge, of the origin of living matter?

Origin of living matter—abiogenesis and biogenesis. In the case of all conspicuous and easily-studied organisms, it has been obvious, since the study of nature began, that living beings arise by generation from living beings of a like kind; but before the latter part of the 17th century, learned and unlearned alike shared the conviction that this rule was not of universal application, and that multitudes of the smaller and more obscure organisms were produced by the fermentation of not-living, and especially of putrefying dead matter, by what was then termed *generatio æquivoca* or *spontanea*, and is now called *abiogenesis*. Redi showed that the general belief was erroneous in a multitude of instances; Spallanzani added largely to the list; while the investigations of the scientific helminthologists of the present century have eliminated a further category of cases in which it was possible to doubt the applicability of the rule "*omne vivum e vivo*" to the more complex organisms which constitute the present fauna and flora of the earth. Even the most extravagant supporters of abiogenesis at the present day do not pretend that organisms of higher rank than the lowest *Fungi* and *Protozoa* are produced otherwise than by generation from pre-existing organisms. But it is pretended that *Bacteria*, *Torulæ*, certain *Fungi*, and "Monads" are developed under conditions which render it impossible that these organisms should have proceeded directly from living matter.

The experimental evidence adduced in favour of this proposition is always of one kind, and the reasoning on which the conclusion that abiogenesis occurs is based may be stated in the following form:—

All living matter is killed by being heated to n degrees.

The contents of the closed vessel A have been heated to n degrees.

Therefore, all living matter which may have existed therein has been killed.

But living *Bacteria*, &c., have appeared in these contents subsequently to their being heated.

Therefore, they have been formed abiogenetically.

No objection can be taken to the logical form of this reasoning, but it is obvious that its applicability to any particular case depends entirely upon the validity, in that case, of the first and second propositions.

Suppose a fluid to be full of *Bacteria* in active motion, what evidence have we that they are killed when that fluid is heated to n degrees? There is but one kind of conclusive evidence, namely, that from that time forth no living *Bacteria* make their appearance in the liquid, supposing it to be properly protected from the intrusion of fresh *Bacteria*. The only other evidence, that, for example, which may be furnished by the cessation of the motion of the *Bacteria*, and such slight changes as our microscopes permit us to observe in their optical characters, is simply presumptive evidence of death, and no more conclusive than the stillness and paleness of a man in a swoon are proof that he is dead. And the caution is the more necessary in the case of *Bacteria*, since many of them naturally pass a considerable part of their existence in a condition in which they show no marks of life whatever save growth and multiplication.

If indeed it could be proved that, in cases which are not open to doubt, living matter is always and invariably killed at precisely the same temperature, there might be some ground for the assumption, that, in those which are obscure, death must take place under the same circumstances. But what are the facts? It has been pointed out at the commencement of this article, that the range of high temperatures between the lowest, at which some living things are certainly killed, and the highest, at which others certainly live, is rather more than 100° Fahr., that is to say, between 104° Fahr. and 208° Fahr. It makes no sort of difference to the argument how living beings have come to be able to bear such a temperature as the last mentioned; the fact that they do so is sufficient to prove that, under certain conditions, such a temperature is not sufficient to destroy life.

Thus it appears that there is no ground for the assumption that all living matter is killed at some given temperature between 104° and 208° Fahr.

But, further, there is very strong reason for believing that the influence of temperature on life is greatly modified, first, by the nature of the medium in which organisms are placed, and, secondly, by the length of time during which any given temperature is kept up.

On this point recent experiments made by Dr Roberts of Manchester are of great importance. He found, for example, as every other careful experimenter has done, that ordinary infusion of hay boiled for a few minutes was sterilized, that is to say, no development of *Bacteria* took place in it, however long it might be kept; while if the infusion was rendered alkaline with ammonia or liquor potassæ, it was not sterilized except after an exposure to the heat of boiling water for more than an hour. Sometimes it became productive after two hours, and once after three hours of such exposure. Is it to be imagined that, in the case of the alkalized hay infusion, the heat applied really killed the *Bacteria* which existed in the infusion, and that *Bacteria* of identically the same kind were generated afresh out of the dead matter? or is it more probable that the powers of resistance of the *Bacteria* to heat were simply increased by the alkalinity of the infusion? The statement of the questions surely renders it unnecessary to answer them.

Dr Roberts further proves that there are two factors in the induction of sterilization, the degree of heat on the one hand, and the duration of its application on the other. A longer exposure to a lower temperature was equivalent to a shorter exposure to a higher temperature. "For example, speaking roughly, an exposure of an hour and a half to a heat of 212° Fahr. appeared to be equivalent to an exposure for fifteen minutes to a heat of 228° Fahr."[1]

It is hard to conceive what explanation can be offered of this fact, except that, under the conditions of the experiment, the organisms were either all affected by the first incidence of the heat in such a way as only to arrest some of their vital functions, and to leave a potentiality of life in them, such as exists in some kinds of dried living matter; or that they individually differed very much in their powers of resistance, and that some were able to withstand heat much longer than others.

Under these circumstances it will be evident, that no experimental evidence that a liquid may be heated to n degrees, and yet subsequently give rise to living organisms, is of the smallest value as proof that abiogenesis has taken place, and for two reasons:—Firstly, there is no proof that organisms of the kind in question are dead, except their permanent incapacity to grow and reproduce their kind; and secondly, since we know that conditions may largely modify the power of resistance of such organisms to heat, it is far more probable that such conditions existed in the experiment in question, than that the organisms were generated afresh out of dead matter.

Not only is the kind of evidence adduced in favour of abiogenesis logically insufficient to furnish proof of its occurrence, but it may be stated as a well-based induction, that the more careful the investigator, and the more complete his mastery over the endless practical difficulties which surround experimentation on this subject, the more certain are his experiments to give a negative result; while positive results are no less sure to crown the efforts of the clumsy and the careless.

Abiogenesis and the doctrine of evolution. It is argued that a belief in abiogenesis is a necessary corollary from the doctrine of Evolution. This may be true of the occurrence of abiogenesis at some time; but if the present day, or any recorded epoch of geological time, be in question, the exact contrary holds good. If all living beings have been evolved from pre-existing forms of life, it is enough that a single particle of living protoplasm should once have appeared on the globe, as the result of no matter what agency. In the eyes of a consistent evolutionist any further independent formation of protoplasm would be sheer waste.

The production of living matter since the time of its first appearance, only by way of biogenesis, implies that the specific forms of the lower kinds of life have undergone but little change in the course of geological time, and this is said to be inconsistent with the doctrine of evolution. But, in the first place, the fact is not inconsistent with the doctrine of evolution properly understood, that doctrine being perfectly consistent with either the progression, the retrogression, or the stationary condition of any particular species for indefinite periods of time; and secondly, if it were, it would be so much the worse for the doctrine of evolution, inasmuch as it is unquestionably true, that certain, even highly organized, forms of life have persisted without any sensible change for very long periods. **Persistent types of life.** The *Terebratula psittacea* of the present day, for example, is not distinguishable from that of the Cretaceous epoch, while the highly organised Teleostean fish, *Beryx*, of the Chalk differed only in minute specific characters from that which now lives. Is it seriously suggested that the existing *Terebratulæ* and *Beryces* are not the lineal descendants of their Cretaceous ancestors, but that their modern representatives have been independently developed from primordial germs in the interval? But if this is too fantastic a suggestion for grave consideration, why are we to believe that the *Globigerinæ* of the present day are not lineally descended from the Cretaceous forms? And if their unchanged generations have succeeded one another for all the enormous time represented by the deposition of the Chalk and that of the Tertiary and Quaternary deposits, what difficulty is there in supposing that they may not have persisted unchanged for a greatly longer period?

The fact is, that at the present moment there is not a shadow of trustworthy direct evidence that abiogenesis does take place, or has taken place, within the period during which the existence of life on the globe is recorded. But it need hardly be pointed out, that the fact does not in the slightest degree interfere with any conclusion that may be arrived at deductively from other considerations that, at some time or other, abiogenesis must have taken place.

If the hypothesis of evolution is true, living matter must have arisen from not-living matter; for by the hypothesis, the condition of the globe was at one time such that living matter could not have existed in it,[2] life being entirely incompatible with the gaseous state. But living matter once originated, there is no necessity for another origination, since the hypothesis postulates the unlimited, though perhaps not indefinite, modifiability of such matter.

The origin of species. Of the causes which have led to the origination of living matter, then, it may be said that we know absolutely nothing. But postulating the existence of living matter endowed with that power of hereditary transmission, and with that tendency to vary which is found in all such matter, Mr Darwin has shown good reasons for believing that the interaction between living matter and surrounding conditions, which results in the survival of the fittest, is sufficient to account for the gradual evolution of plants and animals from their simplest to their most complicated forms, and for the known phenomena of Morphology, Physiology, and Distribution.

[1] *Proceedings of the Royal Society*, No. 152, p. 200.

[2] It makes no difference if we adopt Sir W. Thomson's hypothesis, and suppose that the germs of living things have been transported to our globe from some other, seeing that there is as much reason for supposing that all stellar and planetary components of the universe are or have been gaseous, as that the earth has passed through this stage.

Mr Darwin has further endeavoured to give a physical explanation of hereditary transmission by his hypothesis of Pangenesis; while he seeks for the principal, if not the only, cause of variation in the influence of changing conditions.

It is on this point that the chief divergence exists among those who accept the doctrine of Evolution in its general outlines. Three views may be taken of the causes of variation:—

The causes of variation

a. In virtue of its molecular structure, the organism may tend to vary. This variability may either be indefinite, or may be limited to certain directions by intrinsic conditions. In the former case, the result of the struggle for existence would be the survival of the fittest among an indefinite number of varieties; in the latter case, it would be the survival of the fittest among a certain set of varieties, the nature and number of which would be predetermined by the molecular structure of the organism.

b. The organism may have no intrinsic tendency to vary, but variation may be brought about by the influence of conditions external to it. And in this case also, the variability induced may be either indefinite or defined by intrinsic limitation.

c. The two former cases may be combined, and variation, may to some extent depend upon intrinsic, and to some extent upon extrinsic, conditions.

At present it can hardly be said that such evidence as would justify the positive adoption of any one of these views exists.

Development a recapitulation of ancestral history.

If all living beings have come into existence by the gradual modification, through a long series of generations, of a primordial living matter, the phenomena of embryonic development ought to be explicable as particular cases of the general law of hereditary transmission. On this view, a tadpole is first a fish, and then a tailed amphibian, provided with both gills and lungs, before it becomes a frog, because the frog was the last term in a series of modifications whereby some ancient fish became an urodele amphibian; and the urodele amphibian became an anurous amphibian. In fact, the development of the embryo is a recapitulation of the ancestral history of the species.

If this be so, it follows that the development of any organism should furnish the key to its ancestral history; and the attempt to decipher the full pedigree of organisms from so much of the family history as is recorded in their development has given rise to a special branch of biological speculation, termed *phylogeny*.

Phylogeny.

In practice, however, the reconstruction of the pedigree of a group from the developmental history of its existing members is fraught with difficulties. It is highly probable that the series of developmental stages of the individual organism never presents more than an abbreviated and condensed summary of ancestral conditions; while this summary is often strangely modified by variation and adaptation to conditions; and it must be confessed that, in most cases, we can do little better than guess what is genuine recapitulation of ancestral forms, and what is the effect of comparatively late adaptation.

Palæontology the historical basis of the doctrine of evolution.

The only perfectly safe foundation for the doctrine of Evolution lies in the historical, or rather archæological, evidence that particular organisms have arisen by the gradual modification of their predecessors, which is furnished by fossil remains. That evidence is daily increasing in amount and in weight; and it is to be hoped that the comparison of the actual pedigree of these organisms with the phenomena of their development may furnish some criterion by which the validity of phylogenetic conclusions, deduced from the facts of embryology alone, may be satisfactorily tested.

LIMITS AND CLASSIFICATION OF THE VEGETABLE KINGDOM.

The fundamental difference which separates the *vegetable kingdom* from the *animal kingdom* is to be found in the modes of nutrition which obtain in each. If we compare a plant and animal reduced to their simplest terms, and consisting, therefore, in each case of a single *cell*, *i.e.*, of a minute mass of protoplasm invested with a cell-wall, while the unicellular plant draws its nutriment by simple imbibition through the cell-wall from the surrounding medium—a process which implies that all its nutriment passes into it in a liquid form—the unicellular animal is able to take in solid nutriment by means of interruptions in the continuity of the cell-wall, and is also able afterwards to reduce this solid food, if of a suitable composition, to the liquid state. And not merely is there a difference of this kind in the mode, there is also one no less important, although less general, in the materials of nutrition. While under present terrestrial conditions those substances, or chemical combinations, which are required for the nutrition of animal organisms, are, as far as we know, nowhere spontaneously produced —that is to say, nowhere apart from the influence of living organisms—materials derived wholly from the inorganic world are sufficient to sustain directly nearly the whole of vegetable life, and therefore, indirectly, of all other life as well. Roughly speaking, while plants are able to use for the purposes of nutrition binary compounds, such as carbon dioxide (CO_2), water (H_2O), and ammonia (NH_3), animals are essentially dependent on the same elements as enter into these compounds, but mostly in a higher state of chemical aggregation than the binary. Plants, therefore, are the "hewers of wood and drawers of water" for other living things. And this property which they so largely possess of constructing, from materials not directly available for animal nutrition, substances which are so, is found to be uniformly attended with the presence of a peculiar green colouring matter, known as chlorophyll, with which a portion of the protoplasm of their cells is tinged. Many plants, however, such as the whole group of *Fungi*, as well as some flowering plants, draw their nutriment from compounds derived from other organisms, and therefore in a higher state of chemical aggregation than those the green plants make use of. So far they approach animals in the mode of their nutrition.

At first sight it might seem a probable hypothesis that the part played by green plants is one which has always been filled by them from the earliest appearance of life upon the earth. It must, however, be noticed that the presence of chlorophyll in the organism depends upon a specialization of some only of its constituent cells, and of part only of the protoplasmic contents of those cells. The inference, which appears to be justified by general biological principles, is that such a specialization is not a thing of primary origin, but has been gradually attained. We are thus, therefore, led to the supposition that the very earliest plants—probably belonging to the same stock as the very oldest animals—were destitute of chlorophyll, and were nourished, as Fungi are now, by the imbibition of substances fitted for their nutrition, but which, in the conditions that accompanied the first appearance of life upon the earth's surface, were produced independently of any organisms. The development of chlorophyll would, therefore, on this view, have to be regarded as a later acquirement.

It is necessary to bear some considerations of this kind in mind in order to clearly apprehend the relation to one another of the different phases of nutrition which the vegetable kingdom includes. The plants, for example, which

we collectively term *Fungi* may, and probably do, include descendants of the original stock which existed before plants possessed chlorophyll at all. No doubt also Fungi comprise plants which are destitute of the chlorophyll possessed by their near allies, in consequence of the degeneration due to a parasitic mode of life. Amongst Flowering Plants we cannot doubt that this has been the case with *Cuscuta*, *Orobanche*, *Lathræa*, and many others. But besides plants which are actually parasitic, there are other degraded allies of green plants, which are content to work up again the imperfectly broken down products of decay. Such plants are termed *Saprophytes;* many examples of them exist amongst the *Orchidaceæ*, such as *Neottia*, *Epipogium*, and *Corallorrhiza*. They live upon the products of the decomposition of vegetable matter, and have more or less completely lost the characteristic green tint of chlorophyll, which would be useless to them if they possessed it. But perhaps the most curious case of the occasional disposition of even green plants to seize upon nutritive matter in an available state of chemical aggregation, is that which is met with in the numerous examples now known of insectivorous plants.

In these latter cases we certainly find morphological adaptation of considerable complexity for purposes of nutrition. But in the vegetable kingdom generally this is certainly the exception rather than the rule. In the animal kingdom it is very different. Amongst plants, however, adaptations of structure which have reference to reproduction assume far greater importance, and these have to a large extent to be relied upon for taxonomic purposes.

Even in the highest plants the physiological division of labour is very small compared with the extent to which it exists amongst animals. From plants of the simplest structure up to the most complicated, the plan of nutrition retains the same broad features. There are few physiological facts of real importance to be observed in the highest terms of the series which may not be equally well studied in the lower.

Amongst such of the lower plants as are aquatic in their mode of life the protoplasm of individual cells is often broken up into fragments, very minute in size, which are set free in the surrounding fluid, and being furnished with *cilia* or motile filamentous prolongations of their protoplasm, rapidly disperse themselves over a considerable area. Such locomotive organisms are usually called *zoospores*. After a time each is invested with a cell-wall composed of *cellulose;* this differs entirely in composition from protoplasm, especially in containing no nitrogen. The production of the cell-wall is not therefore to be regarded as a modification of any part of the protoplasm, but as a segregation of particles of cellulose which were intermixed with it; such a segregation goes on repeatedly, wherever life exists in plant tissues. *Starch*, which is identical in ultimate composition with cellulose, we know to be fabricated from inorganic materials in the chlorophyll-granules (which are specialized portions of protoplasm) under the influence of light. Cellulose is derived from the starch so manufactured, and is dispersed in a state probably of molecular subdivision throughout the protoplasm.

The cellulose wall is not apparently essential to the conception of a vegetable cell, but it is, perhaps, not going too far to say that its existence has conditioned almost all the histological and morphological peculiarities of plant construction. The cell, as already pointed out, although bounded with what is relatively a tough and even rigid cell-wall, is by no means debarred from further nutrition and growth. If destitute of chlorophyll, it may take in nutrient matter, which only requires some moderate elaboration to suit it for incorporation with the protoplasm. If, on the other hand, chlorophyll be present, it will do a good deal of preliminary work in preparing the substances which then, as before, the protoplasm will further appropriate and work upon. In either case the protoplasm of the cell will grow, and as the processes which have been described are generally accompanied by the imbibition of fluid, the cell-wall is subjected in consequence to a considerable tension. The cell-wall, under these circumstances, grows also, and the experiments of Traube seem to show that, given the conditions under which it is known to take place, this growth is almost entirely a physical process. Carried beyond a certain point, tension must result in rupture; but just short of this there appears to be a limit at which the intercalation of new molecules of cellulose is permitted, and so the surface of the cell-wall is enlarged. In *Œdogonium* there is a peculiar arrangement in which fracture actually does take place repeatedly. A circular cleft is formed, which is repaired within by the apposition of an annular splice.

To the growth of a cell so conceived there would seem to be no limit, and in the *Siphophyceæ*, of which *Vaucheria* is a well-known type, there is apparently none. The vegetative portion of these organisms, however complicated, is always formed by the extension of a single cell; the protoplasm is continuous throughout every part, and except when zoospores are formed is never segmented.

This, however, is a rare arrangement. Generally speaking, there comes a time when the protoplasm, by a phase of contractility, divides itself into two masses, and between these a partition of cellulose is formed in the same way as the coat of the naked zoospores already alluded to. Each cell so formed possesses all the capacity for nutrition and growth which the whole possessed. It divides therefore in its turn, and in this way we get the first indication of an aggregate of cells. In the lower plants the cell is complete in itself; in the higher, its independence is more or less merged in that of the others with which it is associated.

This aggregation seems to begin in a purely mechanical way. In *Pleurococcus*, for example, cell division repeated a few times may produce aggregation of, at any rate, four cells. If it were not that the adhesion of these cells seems afterwards to fail, there would be no reason why the mere process of cell division should not produce larger aggregates. But the cell-wall common to two adjacent cells splits through its middle lamina, and the two neighbouring cells part company. In *Hydrodictyon* we have a remarkable example of the formation of an aggregate synthetically, owing to the action of some cause which is quite imperfectly understood, but which is probably purely physical. An enormous number of zoospores are formed from the contents of a parent cell, and these, after tumultuously moving within its cavity, come to rest, and at the same time arrange themselves in the well-known net-like fashion which is characteristic of the full-grown plant. The mechanical persistence of aggregates of cells formed by normal cell division is obviously the step which led to the evolution of such organisms as *Volvox* and *Ulva*, since these are merely aggregates of simple types, such as *Chlamydococcus* and *Pleurococcus*.

At first the independence of the individual aggregated cells would be little impaired. In a *Spirogyra* or *Oscillatoria*, for example, the number of cells present in a filament is probably a matter which does not affect the cells themselves individually, and which conversely they have no power of influencing. The constituent cells might go on dividing, and so form filaments of unlimited length, but which occasionally would be liable to be broken up by arbitrary accident. In *Cladophora*, however, the cells of a filament cease after a time to divide transversely, and

branch by the production of lateral swellings, which are elongated and then divided off by cellulose partitions. It seems reasonable to suppose that branching in this case simply means that one part of the cell-wall is weaker, less fitted to withstand internal tension, than the rest. If the cell-wall were uniform it would stretch uniformly, and the want of uniformity in the cell-wall may probably be traced to its being part of an aggregate. The string of cells is moored by one end, and any motion of the water will cause it to assume an oblique position. It is then unequally influenced by gravity and by light, and these two forces are known to be competent to modify growth in an unsymmetrical manner under such circumstances.

Reasoning of this kind will at any rate suggest the way in which the specialization of individual cells would be a result of their aggregation. With this specialization they would lose an increasing amount of their capacity for independent existence. Specialization of function will, of course, be reflected in corresponding morphological modifications, and thus a mechanical aggregate of independent cell elements gradually passes into a physiological aggregate of interdependent ones.

One obvious penalty of specialization is the loss of the power of reproduction by individual cells when detached. Amongst plants, however, even the highest types preserve some measure of it. It is sufficient to adduce the common horticultural method of propagating Begonias from fragments of the leaves. Such a mode of reproduction in one of the highest plants is essentially the same as that which exists in *Pleurococcus*, and although reproduction from fragments of structures so specialized as a leaf is comparatively rare, there are in almost all plants provisions for agamogenesis, which depend upon the retention by fragments of the organism of this capacity for independent existence. And it may even happen that the perpetuation of the race for considerable periods may come to depend upon such a property. One of the most striking instances of this is the distribution over the British Isles of the American water-weed (*Anacharis*), of which, nevertheless, only the female plant exists in this country. If we had the male, we should have a good instance (and others might be given) of gamogenesis and agamogenesis proceeding side by side in individuals of the same generation, although probably not without the two processes reacting upon one another. Throughout the vegetable kingdom, however, we find gamogenesis and agamogenesis occurring in separate generations, which are often extremely different. The two modes of reproduction are then subject to a cyclical arrangement, and the comparison of the forms under which this *alternation of generations* occurs in different groups throws a good deal of light upon their taxonomic relations. It will be convenient to use the word "*Sporophore*" for the agamogenetic generation, in which special cells (*spores*) are detached from the parent to serve as a means of propagation; while for the gamogenetic generation, in which conjugation takes place, or in which special cells (*oospheres*) are fertilized by antherozoids, and become *oospores*, "*Oophore*" may be employed.

Our present knowledge has rather added to than diminished the difficulty of devising even a plausible phylogenetic classification of the vegetable kingdom. Greater success has, however, been attained in establishing the primary and larger secondary groups, so as to allow us to feel some confidence that they are really natural assemblages. The relation of these groups to one another is a problem, the more than approximate solution of which will probably have to be some time postponed. Many of them appear to represent the later developments of simpler types or aggregates than anything that these groups at present contain. The *Equisetaceæ*, for example, are extremely ancient, yet we know of no form, living or extinct, which enables us to trace the connection of their very remarkable organization with that of other groups. In the animal kingdom the "recapitulation theory" steps in, and obtains from the study of the development of the organism that kind of information which is wanting amongst plants as to the simpler ancestral forms of the different vegetable types. This information, however, is drawn in the animal kingdom to a large extent from the phenomena presented by the differentiation of the sustentative organs of the embryo. For reasons already pointed out, there is nothing analogous to this amongst plants, where the rapid extension of surface is usually the primary object to be attained. The earliest stages in the development of any plant are subject to conditions so simple that there is little room for specialization, and the economy of nutrition has probably generally led to the suppression of recapitulative structural details.

On the other hand, if we derive little help from recapitulation in studying the process of development in plants, from the unicellular stage of spore or oospore, it proves extremely suggestive, if we take in the whole cycle comprised between two processes of gamogenesis, and compare the relations to one another of the gamogenetic and agamogenetic generations, or using the nomenclature introduced above, of the Oophore and Sporophore.

THALLOPHYTA.

Endlicher, in 1836, divided the vegetable kingdom into *Thallophyta* and *Cormophyta*; and these divisions still hold good, though it is by no means easy to frame characters which will strictly limit them. With the exception of the absence in the one, and presence in the other, of the "opposition of stem and root," none of the distinctions which Endlicher pointed out are available now. Throughout the greater part of the *Thallophyta* anything like a distinct segmentation of an axis furnished with lateral appendages is altogether wanting. As thus limited by the absence of a clear differentiation of root, stem, and lateral appendages, this sub-kingdom comprises an assemblage of plants, which were divided by Bishop Agardh, in 1821, into the three well-known groups of *Algæ*, *Fungi*, and *Lichens*. And to these, for reasons which will be presently pointed out, must be added the hitherto problematical group of *Characeæ*.

It has long been seen that, with respect to the three former groups, it was impossible to assign morphological characters which would separate them strictly one from the other. Accordingly Berkeley and Lindley were compelled to fall back on distinctions of a physiological kind. *Algæ* were defined to be generally *aquatic* in their mode of life; *Fungi* and *Lichens*, on the other hand, were *aerial*,—but the former drew their nutriment from the "substratum," while the latter obtained it from the air.

There are several grounds on which this arrangement appears to need reconsideration.

Contrasting, in the first place, *Algæ* and *Fungi*, we now know that the plants belonging to the former group invariably contain chlorophyll, while those belonging to the latter are equally devoid of it. In their morphological aspects, however, the two groups present a remarkable parallelism.

Now, the importance of the presence or absence of chlorophyll, and the difference in the mode of life which results, would have greater weight for classificatory purposes, were we not familiar with instances in other parts of the vegetable kingdom in which it proves to have no value at all. Amongst flowering plants we are acquainted with many cases where plants closely allied in structure to

others in which chlorophyll is normally developed, are entirely destitute of it. These considerations have recently led Cohn and Sachs to treat *Fungi* and *Algæ* as an assemblage of organisms the classification of which is to be attempted on purely morphological grounds. But the assemblage of plants formed by *Algæ* and *Fungi* which thus appear to require classification anew, has been further increased by the addition of two other groups, both regarded quite recently as entirely distinct. In 1868 Schwendener proposed his now well-known theory as to the true nature of Lichens; and although his views have been vigorously attacked, chiefly by writers who seemed to feel that they had a vested interest in their autonomy, the weight of testimony, in the case of those who have examined the matter in a wider spirit, has been to strongly confirm Schwendener's hypothesis. Lichens must now be regarded as composite structures, partly consisting of an alga, partly of a fungus. Quite lately Sachs has pointed out (in the 4th edition of his *Lehrbuch der Botanik*) that *Characeæ* may be compared with the structure and mode of reproduction of some of the *Florideæ*.

Sachs has proposed a classification of the *Thallophyta*, which appears to be the best that our present knowledge admits of. He divides them into four classes—*Protophyta*, *Zygosporeæ*, *Oosporeæ*, and *Carposporeæ*.

1. The *Protophyta* include the simplest plants, and those in which at present gamogenesis is not known to occur. In the *Cyanophyceæ* the protoplasm of the cells is destitute of a nucleus, and, besides containing chlorophyll, is tinged with a peculiar bluish colouring matter, known by the name of phycocyan. In *Palmellaceæ* this peculiar pigment is absent. *Eugleneæ* is a group of well-known but little understood organisms, which must also be placed here provisionally. To these must be added *Schizomycetes* (Bacteria), which are the agents of putrefactive changes in nitrogenous organic matters, and *Saccharomyces* (yeast), which bring about the phenomena known as "fermentation." The *Schizomycetes* appear to be allied in some respects to *Chroococcaceæ* and *Oscillatoriaceæ* amongst the *Cyanophyceæ*. The true position of *Saccharomyces* must for the present be held as problematical; we are still without evidence to conclusively decide in favour either of its autonomy or of its being a peculiar condition of a member of some group of Fungi of more complex development.

2. The *Zygosporeæ* are an assemblage of organisms, none of the members of which attain any high degree of morphological complexity, and in all the subordinate divisions of which the simplest form of gamogenesis, known as *conjugation*, has been observed to take place. Conjugation only differs from the normal process of fertilization in the two protoplasmic bodies which take part in it being precisely similar in bulk and form. Till Thwaites pointed out the contrary in 1848, it was not supposed to be entitled to recognition as a sexual process. But fertilization, as ordinarily understood, only differs in the two conjugating bodies being unlike—that is, in their having undergone differentiation into *antherozoid* and *Oosphere*, the male and female bodies respectively.

The *Zygosporeæ* may be divided, perhaps artificially, into two groups, according as the conjugating cells are motile or non-motile.

In many of the simpler green *Algæ* it has long been known that two kinds of zoospores, differing in size, are produced. To these the terms macrozoospore and microzoospore may be applied. The function of the macrozoospores is purely agamogenetic. The microzoospores, on the other hand, meet in pairs, and fuse into a single protoplasmic body, which Areschoug has termed a *zygozoospore*.

The process was first observed by Pringsheim in *Pandorina*. It has also been observed in *Chlamydomonas*. On these grounds Sachs has placed the whole group of the *Volvocinaceæ* amongst the *Zygosporeæ*. This has, however, been reasonably objected to by Cohn, inasmuch as in *Eudorina* as described by Carter, and in *Volvox* as observed by himself, there is a true process of fertilization by means of antherozoids, and not a simple conjugation. It may be allowed, therefore, provisionally to break up the *Volvocinaceæ*, or rather to restrict the name to the two last-named genera, which may then be removed to the next class, using that of *Pandorineæ* for Volvocinaceous forms, which only exhibit conjugation. *Hydrodictyeæ* should probably be placed here, and also *Confervaceæ* and *Ulvaceæ* in which the conjugation of zoospores has been observed by Areschoug.

Sachs has proposed to associate with the *Zygosporeæ* the *Myxomycetes*, in which the formation of the plasmodium is a kind of complex conjugation. Closely allied in some respects to the *Myxomycetes* are *Chytridineæ* and, more doubtfully, *Protomyces*.

In the second division, in which the conjugating cells are non-motile, must be placed all the more familiar instances of the process—the *Desmidieæ*, the *Diatomaceæ*, the *Zygnemaceæ*, and the *Zygomycetes* as a fungoid type.

3. The *Oosporeæ* must include the *Volvocinaceæ*, in the limited sense already explained, and also *Sphæroplea*—a form divorced on much the same grounds from *Confervaceæ*. *Fucus* affords the best known type of reproduction belonging to this group. The antherozoids are ciliate bodies discharged from *antheridia*; the *oospheres* are naked protoplasmic masses originally contained in *oogonia*. The antherozoids gather round them in such numbers as to impart to them a movement of rotation. They eventually completely blend with the oosphere, which becomes surrounded with a coat, and sinks to the bottom of the fluid in which it has hitherto been suspended. It is now an oospore, and speedily undergoes a process of cell division, which gives rise to an individual of the new generation. Near the *Fucaceæ* a place must probably be assigned to the *Phæosporeæ*. The remaining groups which fall into *Oosporeæ* are *Cœloblastæ* and *Œdogonieæ*. *Cœloblastæ* have their protoplasm unsegmented throughout the vegetative portions of the organism. They include forms which are partly algoid, such as *Vaucheria* and the *Siphophyceæ* generally, partly fungoid, as *Peronosporeæ* and *Saprolegnieæ*. In all other respects, except the presence or absence of chlorophyll, they closely agree with one another, and the consideration of this fact has led, perhaps more than any other fact, to the breaking down of the barrier between Algæ and Fungi.

4. The *Carposporeæ*[1] agree with the *Oosporeæ* in so far that the two sexual organs contribute in very different proportions to the formation of the sexual product. While the male only stimulates its development, the female supplies the material for the whole subsequent growth.

The female organ, or *carpogonium*, may consist of one or more cells. The male organ varies very considerably in the different subordinate groups. Fertilization may, as in the *Oosporeæ*, be effected by antherozoids (which may be actively motile or passively locomotive), or by a kind of conjugation, or even by a mere apposition of the male organ and subsequent diffusion of the fertilizing medium. The product of the act of fertilization is sometimes a single cell developing directly into a new individual (*Chara*). In other cases the fertilized female organ produces zoospores, and still more commonly a multicellular mass in which spores are finally developed. This involves an alternation of the generations of the type of that met with in the sporocarp of *Muscineæ*.

[1] See Sachs's *Lehrbuch*, 4th ed. pp. 240-243.

And we may have every grade of development, from the simplest case, in which the sporocarp appears as a mere appendage of the parent plant of inconsiderable dimensions, to the most extreme condition in the other direction, in which the sporocarp is capable of independent growth, and therefore represents a second generation which is entirely distinct (*sporophore*). The sporocarp also differs essentially from the oospore in the fact that cells contribute to its formation which have not been directly influenced by fertilization, and that in consequence the part of the fruit which produces the spores is surrounded by what—for want of a more convenient term—we may call the pericarp, in which no spores are developed, and which serves as a mere protective investment, or is subsequently drawn upon for purposes of nutrition. In *Phycomyces*, which belongs to *Zygosporeæ*, it is noteworthy that there is a kind of anticipation of the development of a protective investment to the zygospores.

The principal types of the *Carposporeæ* include all the more highly developed forms both of Algæ and Fungi.

In *Coleochæteæ* the carpogonium terminates in an open canal, and fertilization is effected by motile antherozoids.

In *Florideæ*, in the simplest type (*Nemalion*), the carpogonium resembles that of *Coleochæteæ*, only the terminal tube (trichogyne) is closed and not open. Fertilization is effected by passively motile antherozoids, which adhere to the trichogyne. In *Ceramieæ* the carpogonium, even before fertilization, consists of numerous cells, a lateral row of which—the trichophore—bears the trichogyne. Neither trichogyne nor trichophore, however, take any part in the development of the sporocarp. The pericarp is produced by a process of budding from cells beneath the carpogonium.

In the genus *Dudresnaya* the process of fertilization becomes very complicated, and in fact involves a double process, of which the first stage consists in the application of antherozoids to a trichogyne; and the second in the development from below the trichophore of a "conducting filament" which conveys the fertilizing influence to the terminal cells of a number of small branches, with which it successively conjugates; at each point of conjugation a sporocarp is developed. Amongst the *Ceramieæ* there is something comparable to this double process; the fertilizing influence which is conveyed by antherozoids to the trichogyne must afterwards be communicated by a process of diffusion from the trichophore to the cell from which the spores are developed.

Characeæ are now to be regarded as a reduced type of *Carposporeæ*. The carpogonium is supported by two basal cells with oblique septa, which it seems quite reasonable to accept as the rudiments of a trichophore. There is, of course, no trichogyne, and fertilization is effected by motile antherozoids, and the pericarp is developed before instead of after this process. In *Chara* the main axis is clothed with a peculiar cortical tissue, which grows over it from the nodes, and is clearly comparable with that which exists in the *Ceramieæ*.

Fungi contribute to the *Carposporeæ* the *Ascomycetes*, *Æcidiomycetes*, and *Basidiomycetes*. In the first and last of these groups the existence of a sexual process preceding the development of the sporocarp is now known. *Ascobolus* has been studied by Janczewski, and the essential features of the sexual process are closely comparable to those of *Ceramieæ*. The carpogonium consists of a row of cells; the terminal one is fertilized by the ramified "pollinodium," and from the central cell of the carpogonium a number of filaments branch out which bear the asci, while the pericarp is formed by the branching of the mycelium below the carpogonium.

Lichenes, in so far as the hyphæ and fructification are concerned, are essentially ascomycetous fungi. Their gonidia are referable to different groups of algæ. The two sets of organisms live together in a kind of modified commensality. The algæ are able to sustain their companion fungus without succumbing to the demands of its nutrition.

Cormophyta.

Alternation of generations exists amongst the *Thallophyta*. But, as in *Œdogonium*, it assumes the form of an occasional occurrence of gamogenesis after more or less prolonged periods of agamogenesis; a series of sporophores is interrupted by the intercalation of an oophore. Amongst the *Cormophyta*, however, we have generally a regular alternation of oophore and sporophore. Both may, however, propagate themselves by the detachment of more or less specialized gemmæ. But apart from this, the agamogenetic production of spores and the gamogenetic production of oospores regularly follow one another.

Cohn, in a classification of Cryptogams published in 1872, established the groups *Bryophyta* and *Pteridophyta*, which, added to *Phanerogamæ*, constitute the groups into which *Cormophyta* appear best susceptible of division.

1. *Bryophyta.*—In such a case as *Œdogonium*, sporophore and oophore each attain a tolerably equal degree of vegetative development. In others, however, this may be very much curtailed in one or the other generation. Amongst the *Thallophyta* the sporophore not uncommonly suffers this reduction. Thus in *Mucor* the zygospore only develops a short filament, which terminates in a sporangium filled with spores. If we suppose the filament suppressed, the spores belonging to the second generation will be produced directly from the oospore itself. Thus, amongst the *Cœloblastæ*, in *Cystopus* the oospore produces zoospores, and, according to Cienkowski, this is also the case with *Volvox*. In such cases the oospore itself is the sporophore. Amongst the *Bryophyta* there is an alternation of generations which is hardly less abridged. The oophore—which in *Hepaticæ* is often a thalloid body, while in mosses it is a leafy plant—bears female organs (*archegonia*) and male organs (*antheridia*). The oospore, or fertilized central cell of the archegonium, gives rise to a complicated structure which produces the spores. The first division of the oospore appears to be inclined to the axis of the archegonium. The sporophore is retained in a kind of attachment to the oophore, and never attains to any vegetative development of its own. From the fact that the vegetative structure of some *Hepaticæ* is thalloid and leafless (*Aneura*), while in others (*Marchantia*) leaves are present in a very reduced condition, it may be inferred that the former have lost their leaves rather than that they represent an original leafless condition. The ancestral type of the *Bryophyta* was probably more like a moss than like any of the *Hepaticæ*. And it is worth while considering what claims *Chara* may have to be regarded as a transition from the *Thallophyta*, of which it is an anomalous type in its possession of distinct lateral appendages to the axis. Cohn placed it amongst the *Bryophyta*; but its removal to the *Thallophyta* probably assigned it its true position. The investment of the carpogonium, however, cannot have more than an analogy with an archegonium. The fertilized carpogonium (sporocarp) might perhaps be regarded as a very reduced form of that of the *Bryophyta*, producing only a single spore. It is certainly an interesting and it may be a significant point, that the spore of *Characeæ* produces in germinating a filamentous chain of cells, apparently comparable to the protonema of mosses, and from this the fully developed sexual plant is produced as a lateral bud.

2. *Pteridophyta* are sharply divided from *Bryophyta* by the high vegetative development of the sporophore and

gradually increasing suppression of that of the oophore. This never, however, as in the succeeding group, completely loses its independence of the sporophore.

The whole direction of the attempts at classifying the *Pteridophyta*, which correspond to the so-called vascular Cryptogams, has been completely changed by Fankhauser's discovery of the long-sought reproduction of *Lycopodium*. It proves to be totally unlike that of *Selaginella*, which, from the close agreement that exists between the two types in every other respect, it might have been expected to closely resemble. On the contrary, in the formation of a monœcious subterranean prothallus, it may be compared to *Ophioglosseæ*. Yet, as Sachs has pointed out, it is impossible to use this striking divergence for the purpose of breaking up a group of plants which in all respects is perfectly congruous. The anomaly of forms so closely allied, exhibiting two modes of gamogenesis, has now, however, found a parallel amongst the *Filicales*, in which group *Rhizocarpeæ* seem to find their proper place.

The *Pteridophyta* are divisible into three probably natural classes, which may be briefly defined by the following characters, in themselves, no doubt, artificial:—

i. *Filicales*.—Leaves highly developed and bearing numerous sporangia.

ii. *Equisetaceæ*.—Leaves rudimentary, reduced to sheaths on the barren stems, the fertile ones bearing 5–10 sporangia.

iii. *Dichotomæ*.—Leaves small, simple; sporangia solitary.

The *Filicales* include, according to the arrangement proposed by Sachs, three orders. In *Stipulatæ* the sporangia are not trichomes, but are either wholly endogenous products as in *Ophioglossum*, or are formed from cellular protuberances, and the tissue beneath the epidermis takes part in the formation of spores (*Marattiaceæ*). In *Filices* proper the sporangia are, as already mentioned, trichomes, and these are developed upon the normal fronds. In *Rhizocarpeæ* the sporangia are borne by metamorphosed leaves, which are united into a capsular body in a way comparable to that in which carpels bearing ovules are united into a syncarpous ovary. The germination of the spores also presents important differences in the different orders amongst the *Stipulatæ*. In *Ophioglossaceæ* it gives rise to a tuberous monœcious oophore (prothallium), destitute of chlorophyll. In *Osmunda* the prothallium exhibits some tendency to become diœcious; it resembles the normal type of prothallium in ferns, but has a kind of mid-rib, and produces adventitious shoots from marginal cells. These shoots become detached, and constitute a mode of agamogenesis. Such a structure cannot fail to recall the thalloid *Hepaticæ*, which also possess a mode of agamogenesis by means of gemmules (*e.g.*, *Marchantia*). In *Rhizocarpeæ* the diœcious condition of the oophore has been carried so far that it is indicated even in the spores themselves; the microspores are male, the macrospores female. In *Salvinia* there is a rudimentary prothallium bearing the antheridia; and a last trace of such a structure appears to exist in *Marsilea* and *Pilularia*. The macrospore also develops a prothallium, in which numerous archegonia are produced, one only of which is fertilized. The development of the prothallium is so far external to the macrospore that it effects its rupture at the apical papilla. In the *Rhizocarpeæ* the development of the oophore has been almost entirely compressed within the limits of the spore.

Equisetaceæ call for little remark as regards the oophore. It is diœcious, and irregularly branched, but in other respects there is a close agreement with the oophore of ferns.

The *Dichotomæ* present in the morphology of the oophore a parallel series with the *Filicales*. The *Lycopodiaceæ* develop from the single form of spores which they possess a monœcious subterranean prothallium like that of *Ophioglosseæ*. The *Ligulatæ* (comprising *Selaginella* and *Isoetes*) produce, like *Rhizocarpeæ*, microspores and macrospores. In this group the suppression of the oophore is carried still further; the microspores possess, according to Millardet, the merest rudiment of a male prothallium. The macrospores produce a female prothallium, which is an endogenous structure in even a higher degree than in the *Rhizocarpeæ*. The first divisions of the oospore have not as yet been sufficiently studied. But while in Ferns proper, *Equisetaceæ* and *Ophioglossaceæ*, the first septum is more or less inclined to the axis of the archegonium, it is parallel with it in *Rhizocarpeæ* (a position into which a very oblique inclination would readily pass), while in *Selaginella* it is at right angles with it.

3. *Phanerogamæ*.—In at any rate two of the three groups of the *Pteridophyta* we see that the progressive tendency of the oophore (prothallium) is to lose its independence. In *Ophioglosseæ*, *Filices*, and *Equisetaceæ*, its growth, independent of the spore, often continues for a considerable period. In *Rhizocarpeæ* and *Lycopodiaceæ*, where male and female spores are produced, the oophore remains attached to the spore, although protruding from it. In *Isoetes* it fills the cavity of the macrospore as a mass of tissue, and the bounding wall is only ruptured to allow the access of the antherozoids to the archegonia. In the *Phanerogamæ* even so small an assertion of independence as this is suppressed. The macrospore (embryo-sac) is never detached from the sporophore previous to fertilization, and the oophore, which is moderately developed in the *Gymnospermæ*, but in the *Angiospermæ* is reduced to the merest rudiment, always remains entirely enclosed within the macrospore.

In the *Gymnospermæ* the endosperm is the homologue of the prothallium (oophore). The so-called "corpuscula" are the archegonia, or rather the central cells of reduced archegonia (secondary embryo-sacs of Henfrey). The neck of the archegonium is represented by the "rosette" first described by Hofmeister. Strasburger has pointed out that a small portion of the contents of the central cells is divided off at the upper end, and this is the rudiment of the canal cell which, running the length of the neck of the archegonium in the *Bryophyta* and *Pteridophyta*, leaves a pervious track by its deliquescence for the access of the antherozoids to the central cell. Strasburger considers all the rest of the contents of the embryo-sac to be the equivalent of the oosphere. The result of fertilization is to cause a transverse partition of the lower part of the oosphere, as in *Selaginella*. From the lower cell thus constituted, by successive longitudinal and transverse partitions, the suspensors are developed, the ends of each of which bear an embryo. It is noteworthy that the development of a suspensor as an intermediate structure between the fertilized oosphere and the embryo is also met with in *Selaginella*.

It only remains to point out, as far as they are understood, the comparable structures in *Angiospermæ*. Here the prothallium (oophore) has completely disappeared, unless we regard, with Sachs, the "antipodal cells" as a last rudimentary trace; their appearance is, however, inconstant. Within the embryo-sac (macrospore) "embryo-vesicles" are formed, usually two or three in number. One of these is the oosphere, and may be compared to the central cell of an evanescent archegonium, to which another of the "embryo-vesicles" performs the function of a canal cell; for while it is that which is usually in nearest proximity to the pollen tube, it only apparently transmits the fertilizing influence. In a few cases this dormant embryo-vesicle is replaced by a somewhat more highly developed arrangement—the

filamentary apparatus—the homology of which, with a canal cell, is more obvious.

The foregoing sketch indicates, in a very brief manner, the outlines of the classification of the vegetable kingdom, which has been constructed in the light of the most recent studies of the comparative structure of different types. It is sufficient to say, that a detailed consideration of the new relations in which many of the groups now stand to one another by no means diminishes, but strongly confirms, the soundness of the arrangement.

The following table gives the classification in a synoptic form:—

VEGETABILIA.

SUB-KINGDOM A. THALLOPHYTA.

With Chlorophyll. (ALGÆ.)	Without Chlorophyll. (FUNGI.)
Class 1. PROTOPHYTA.	
i. *Cyanophyceæ.* Chroococcaceæ. Oscillatorieæ, &c.	i. *Schizomycetes.*
ii. *Palmellaceæ.* [? Eugleneæ.]	ii. *Saccharomyces.*
Class 2. ZYGOSPOREÆ.	
α. Conjugating cells motile.	
i. *Pandorineæ.* [? Hydrodictyeæ.]	i. *Myxomycetes.*
ii. *Confervaceæ.*	ii. *Chytridineæ.*
iii. *Ulvaceæ.*	
β. Conjugating cells non-motile.	
iv. *Conjugatæ.* Desmidieæ, &c.	[? Protomyces.]
	iii. *Zygomycetes.* Mucorini, &c.
Class 3. OOSPOREÆ.	
i. *Volvocineæ.*	
ii. *Sphæroplea.*	
iii. *Cœloblastæ.* Siphophyceæ.	i. *Cœloblastæ.* Ancylisteæ. Saprolegnieæ. Peronosporeæ.
iv. *Œdogonieæ.*	
v. *Fucaceæ.* [Phæosporeæ.]	
Class 4. CARPOSPOREÆ.	
i. *Coleochæteæ.*	i. *Ascomycetes.* Lichenes, &c.
ii. *Florideæ.* Nemalieæ. Ceramieæ, &c.	ii. *Æcidiomycetes.*
iii. *Characeæ.*	iii. *Basidiomycetes.*

SUB-KINGDOM B. CORMOPHYTA.

Series I. BRYOPHYTA.

Class 1. Musci.

Class 2. Hepaticæ.

Series II. PTERIDOPHYTA.

Class 1. Filicales.

i. *Stipulatæ.*
Ophioglosseæ.
Marattiaceæ.
ii. *Filices.*
iii. *Rhizocarpeæ.*

Class 2. Equisetaceæ.

Class 3. Dichotomæ.

i. *Lycopodiaceæ.*
Lycopodieæ.
Psiloteæ.
Phylloglosseæ.
ii. *Ligulatæ.*
Selaginelleæ.
Isoeteæ.

Series III. PHANEROGAMÆ.

Class 1. Gymnospermæ.

Class 2. Angiospermæ.

i. *Monocotyledones.*
ii. *Dicotyledones.*

See *A Text-Book of Botany, Morphological and Physiological*, by Julius Sachs (3d edition), translated by A. W. Bennett, assisted by W. T. Thiselton Dyer; *Lehrbuch der Botanik*, von Dr Julius Sachs, vierte Auflage; *Quarterly Journal of Microscopical Science*, new series, vols. i.-xv. (W. T. T. D.)

BION, the second of the three Greek bucolic poets, was born in the neighbourhood of Smyrna,—according to Suidas, at Phlossa on the River Meles. The few facts known to us of his life are to be gathered from the beautiful Ἐπιτάφιος Βίωνος of his friend and scholar Moschus. From his account it appears that Bion left his native country and, during the latter part of his life, resided in Sicily and cultivated the form of poetry peculiarly associated with that island. He was contemporary with Theocritus and somewhat older than Moschus. His death was due to poison, administered to him by some jealous rivals who afterwards suffered the penalty of their crime. The subjects of his verses are described by Moschus as "Love and Pan;" but though his works are included in the general class of bucolic poetry, they have little of the pastoral imagery and description characteristic of Theocritus. They breathe a more refined air of sentiment, and show traces of the overstrained reflection frequently observable in later developments of pastoral poetry. The longest and best of his extant works is the *Lament for Adonis* (Ἐπιτάφιος Ἀδώνιδος), the prototype of many modern poems. His other pieces are short and in many cases fragmentary. Two of the Idylls (xix. and xx.) of Theocritus are frequently ascribed to him. Bion and Moschus are edited separately by Hermann (1849) and Ziegler (1869). The best annotated editions are those of Heindorf (1810), Meineke (1856), Ahrens (1855–9), Fritsche (1870), all of which contain also the works of Theocritus. The *Epitaphius Adonidis* is edited separately by Ahrens, 1854.

BIOT, JEAN BAPTISTE, French physicist, was born at Paris, 21st April 1774. After leaving school he served for a short time in the artillery, but again resumed his studies at the École Polytechnique. He distinguished himself in mathematics, and was appointed to a professorship at Beauvais. There he carried on his researches with the greatest assiduity, and gained the acquaintance and friendship of Laplace, from whom he solicited and obtained the favour of reading the proof-sheets of the *Mécanique Céleste*. In 1800 he was recalled to Paris as professor of physics at the Collége de France. Three years later he was elected a member of the Academy of Sciences, a distinction rarely accorded to one so young as he was. In 1803 Biot, in concert with Arago, investigated the refracting properties of gases, and in the following year accompanied Gay-Lussac in his balloon ascent. He was again associated with Arago in the great undertaking of the measurement of an arc of the meridian in Spain, and at a later date (1817–18) he crossed over to Britain and mea-

sured carefully the length of the seconds pendulum along an arc extending to the extreme north of Shetland. In 1814 he was made a chevalier of the Legion of Honour, an order of which he became a commander in 1849. He was a member of the French Academy and of the Academy of Inscriptions and Belles-Lettres, as well as of most foreign scientific societies. In 1840 he received the Rumford gold medal for his researches in polarized light. He died at an advanced age in 1862. Biot's researches extended to almost every branch of physical science; but his greatest discoveries were made in the department of optics, mainly in connection with the polarization of light. He had a thorough command of the best methods of analysis, and applied mathematics rigidly and successfully to physical phenomena. His various dissertations in the *Memoirs* of the Academy are very numerous; a selection of the more valuable was published in 1858. His systematic works—*Traité Elémentaire d'Astronomie Physique* (1805, 3d ed., 1841–57, 6 vols.), *Traité de Physique* (1816, 4 vols.), *Précis Elémentaire de Physique Expérimentale* (1817, 3d ed., 1824, 3 vols.)—are of great merit, though necessarily in some respects behind the present state of physical science.

BIR, or BIREJIK (the former being its Arabic and the latter its Turkish name), a town of Asiatic Turkey, in the pashalik of Rakka, built on the side of a chalky range of hills that skirts the left bank of the Euphrates, about 90 miles N.E. of Aleppo, in long. 38° 6′ E., and lat. 36° 48′ N. It consists of about 2000 houses, surrounded by a dilapidated wall and protected by the citadel of Kalai-Beda, which, with its earthquake-shattered interior, occupies a precipitous eminence cut off from the town. Bir is situated on the main route from Aleppo to Orfa, Diarbekr, and the Persian frontier, and had formerly a considerable trade with Baghdad by means of the river. It is now a post and telegraph station. A ferry seems to have crossed the river at this spot from time immemorial, Abraham himself having made use of it, according to tradition, on his passage from Haran to Canaan. The town is identified with the ancient Birtha or Britha, where the emperor Julian rested on his march to Maogamalcha, and found quarters for his army in one extensive palace. In the English Euphrates expedition Bir was frequently visited, Fort William, one of the principal places of rendezvous, being about 2 miles further down on the other side of the river. (See view in Chesney's *Narrative of Euphrates Expedition*, 1868.)

BÍRBHÚM, a district of British India, within the Bardwán division, under the lieutenant-governor of Bengal, situated between 24° 23′ 10″ and 23° 34′ 51″ N. lat., and 88° 3′ 54″ and 87° 7′ 41″ E. long. It is bounded on the N. by the districts of Santál Parganás and Bhágalpur; on the E. by the districts of Murshidábád and Bardwán; on the S. by the River Ajai, separating it from the district of Bardwán; and on the W. by the districts of the Santál Parganás. The census of 1872 returned the area of the district at 1344 square miles, and the total population at 695,921 souls, residing in 2471 villages and 159,904 houses. Pressure of population per square mile, 518; per village, 282; per house, 4·3. Of the total population, 576,908, or 82·9 per cent., were Hindus; 111,795, or 16·1 per cent., Mahometans; 249 Christians; and 3440, consisting principally of aboriginal tribes, of unspecified religions. The eastern portion of the district is the ordinary alluvial plain of the Gangetic Delta; the western part consists of undulating beds of laterite resting on a rock basis, and covered with small scrub jungle. The Ajai, Bakheswar, and Mor or Mauraksh, are the principal rivers of the district, but they are merely hill streams and only navigable in the rains. Rice, wheat, sugar-cane, pulses, oil-seeds, and mulberry form the agricultural products of the district. The chief manufactures are silk, silk cloth, and lacquered ware. The principal seats of trade are Dubrájpur, Ilámbázár, Bolpur, Sinthiá, Purandarpur, Krinnáhár, Muhammad Bázár, and Ahmadpur. The total net revenue of the district in 1870–71 amounted to £97,979; the civil expenditure to £27,278. The land tax forms the most important item of revenue. In 1870-71 it amounted to £73,261, paid by 556 estates, held by 2036 proprietors, under the Permanent Settlement as in other parts of Bengal. The district and municipal police force amounted to 320 officers and men, at a total cost of £5895 in 1871. Besides these there were 8554 men of the village watch, maintained at a total cost of £23,074, paid by service lands and by the villagers. In 1872 Bírbhúm contained 604 schools, attended by 9338 pupils, costing £989 to the state for the education of its people. There are seven principal roads in the district, the total mileage being 191, and the average cost of their maintenance £1781. Thirty-three miles of the East Indian Railway lie within the district. Until lately Bírbhúm was considered to be the healthiest district in Bengal; but during the past few years epidemic fever has made havoc among the rural population of the eastern portion of the district.

BÍRBHÚM, or SURÍ, the principal town and administrative headquarters of the district of the same name, is situated in 23° 54′ 25″ N. lat., and 87° 34′ 23″ E. long. In 1872 it contained a population of 9001, of whom 6746 were Hindus, 2056 Mahometans, 187 Christians, and 12 of unspecified religions. Municipal income of the town in 1871, £483, 18s.; expenditure, £473, 8s.; rate of municipal taxation, 1s. 8d. per head.

BIRCH (*Betula*), a genus of arboraceous plants constituting the principal portion of the natural order *Betulaceæ*. The various species of birch are mostly trees of medium size, but several of them are merely shrubs. They are as a rule of a very hardy character, thriving best in northern latitudes,—the trees having round, slender branches, and serrate deciduous leaves, with barren and fertile catkins on the same tree and winged seeds. The bark in most of the trees occurs in fine soft membranous layers, the outer cuticle of which peels off in thin white papery sheets. The common birch (*B. alba*) grows throughout the greater part of Europe, and also in Asia Minor, Siberia, and North America, reaching in the north to the extreme limits of forest vegetation, and stretching southward on the European continent as a forest tree to 45° N. lat., beyond which birches occur only in special situations or as isolated trees. It is one of the most wide-spread and generally useful of forest trees of Russia, occurring in that empire in vast forests, in many instances alone, and in other cases mingled with pines, poplars, and other forest trees. The wood is highly valued by carriage-builders, upholsterers, and turners, on account of its toughness and tenacity, and in Russia it is prized as firewood and a source of charcoal. A very extensive domestic industry in Russia consists in the manufacture of wooden spoons, which are made to the extent of 30,000,000 annually, mostly of birch. Its pliant and flexible branches are made into brooms; and in ancient Rome the fasces of the lictors, with which they cleared the way for the magistrates, were made up of birch rods. A similar use of birch rods has continued among pedagogues to times so recent that the birch is yet, literally or metaphorically, the instrument of school-room discipline. The bark of the common birch is much more durable, and industrially of greater value, than the wood. It is impermeable to water, and is therefore used in northern countries for roofing, for domestic utensils, for boxes and jars to contain both solid and liquid substances, and for a kind of bark shoes, of which it is estimated 25 millions of pairs are annually worn by the Russian peasantry. The jars and boxes of birch bark made by Russian peasants are often stamped

with very effective patterns. By dry distillation the bark yields an empyreumatic oil, called *diogott* in Russia, used in the preparation of Russia leather; to this oil the peculiar pleasant odour of the leather is due. The bark itself is used in tanning; and by the Samoiedes and Kamchatkans it is ground up and eaten on account of the starchy matter it contains. A sugary sap is drawn from the trunk in the spring before the opening of the leaf-buds, and is fermented into a kind of beer and vinegar. The whole tree, but especially the bark and leaves, has a very pleasant resinous odour, and from the young leaves and buds an essential oil is distilled with water. The leaves are used as fodder in northern latitudes. The species which belong peculiarly to America (*B. lenta, excelsa, nigra, papyracea,* &c.) are generally similar in appearance and properties to *B. alba*, and have the same range of applications. The largest and most valuable is the black birch (*B. lenta*), found abundantly over an extensive area in British North America, growing 60 to 70 feet high, and 2 to 3 feet in diameter. It is a wood most extensively used for furniture and for carriage building, being tough in texture and bearing shocks well, while much of it has a handsome grain, and it is susceptible of a fine polish. The bark, which is dark brown or reddish, and very durable, is used by Indians and backwoodsmen in the same way as the bark of *B. alba* is used in Northern Europe. Concerning the canoe or paper birch (*B. papyracea*), which some regard as a variety of the white birch, Mr Bernard R. Ross, of the Hudson's Bay Company, writes:—"The canoe or paper birch is found as far north as 70° N. on the American continent, but it becomes rare and stunted in the Arctic circle. It is a tree of the greatest value to the inhabitants of the Mackenzie River district in British North America. Its bark is used for the construction of canoes, and for drinking-cups, dishes, and baskets. From the wood, platters, axe handles, snow-shoe frames, and dog sledges are made, and it is worked into articles of furniture which are susceptible of a good polish. The sap which flows in the spring is drawn off and boiled down to an agreeable spirit, or fermented with a birch-wine of considerable alcoholic strength. The bark is also used by the Christianized American Indians as a substitute for paper." A species (*B. Bhojputtra*) growing on the Himalayan Mountains, as high up as 9000 feet, yields large quantities of fine thin papery bark, extensively sent down to the plains as a substitute for wrapping-paper, for covering the "snakes" of hookahs, and for umbrellas. It is also said to be used as writing paper by the mountaineers; and in Kashmir it is in general use for roofing houses.

BIRCH, THOMAS, historical and biographical writer, and one of the early trustees and benefactors of the British Museum, was born in London, November 23, 1705. He was the son of a coffee-mill maker, and was to have followed his father's business, but his active mind and ambition of higher pursuits led him into the paths of literature. His parents were members of the Society of Friends, and therefore he had not the advantages of a university training. But by persevering application to study and to teaching he qualified himself for the ministry of the Church of England. In 1728 he obtained a curacy, and in the same year he married. His wife died in the following year. He was ordained priest in December 1731, and was soon after recommended to the favour of Philip Yorke, then attorney-general, afterwards Lord Chancellor and earl of Hardwicke, to whom he owed his successive preferments in the church. His first benefice was the vicarage of Ulting in Essex. In 1734 he was appointed domestic chaplain to the earl of Kilmarnock, who was beheaded for his share in the rebellion of '45. He afterwards held successively benefices in Pembrokeshire, Gloucestershire, and the city of London. His last church preferment was to the rectory of Depden in Essex, to which he was presented in February 1761. In his latter years he was appointed chaplain to the princess Amelia. His literary attainments procured him election as a fellow of the Royal Society in February 1735, and in the following December he was chosen a member of the Society of Antiquaries. He held the office of Secretary to the Royal Society for thirteen years 1752–1765. From the university of Aberdeen he received the degrees first of M.A., and afterwards (1753) of D.D. The degree of D.D. was also conferred on him about the same time by the archbishop of Canterbury. Dr Birch was engaged in a large number of literary undertakings. His appetite and his capacity for hard work were extraordinary. Besides his diversified labours of compilation and editing, he transcribed many volumes in the library of Lambeth Palace, and carried on an extensive correspondence with literary men. He was an early riser; and amidst all his labours he found time to take part in social enjoyments. He was only in his sixty-first year when he was killed by a fall from his horse in Hampstead Road, January 9, 1766. He bequeathed his books and manuscripts, with part of his pictures and prints, to the British Museum. The rest of his property, in value about £500, he gave to be invested in Government securities, the interest to be applied in augmenting the salaries of the three assistant librarians.

His principal publications were—1. *The General Dictionary, Historical and Critical*, including a new translation of Bayle, and interspersed with several thousand new lives, in 10 volumes fol., 1734–1741. 2. *Thurloe's State Papers*, 7 vols. folio, 1742. 3. *Dr Cudworth's Intellectual System, improved from the Latin edition of Mosheim*; his *Discourse on the true Notion of the Lord's Supper*; and two *Sermons*, with an *Account of his Life and Writings*, 2 vols. 4to, 1743. 4. *The Life of the Honourable Robert Boyle*, 1744, prefixed to an edition of that philosopher's works. 5. *The Lives of Illustrious Persons of Great Britain*, to accompany the engravings of Houbraken and Vertue, 1747–1752. 6. *An Inquiry into the Share which King Charles I. had in the Transactions of the Earl of Glamorgan*, 1747, 8vo. 7. An edition of *Spenser's Faery Queen*, 1751, 3 vols. 4to, with prints from designs by Kent. 8. *The Miscellaneous Works of Sir Walter Raleigh, with his Life*, 1751, 2 vols. 8vo. 9. *The Theological, Moral, Dramatic, and Poetical Works of Mrs Catherine Cockburn, with a Life*, 1751, 2 vols. 8vo. 10. *The Life of Dr Tillotson, Archbishop of Canterbury, compiled chiefly from his Original Papers and Letters*, 1762, 8vo. 11. *Milton's Prose Works*, 1753, 2 vols. 4to, *with a Life*. 12. *Memoirs of the Reign of Queen Elizabeth, from the year* 1581 *till her death*; illustrated from the original papers of Anthony Bacon, Esq., and from other MSS., 1754, 2 vols. 4to. 13. *The History of the Royal Society of London*, 1756 and 1757, 4 vols. 4to. 14. *The Life of Henry Prince of Wales, eldest son of James I., compiled chiefly from his own papers and other MSS.*, 1760, 8vo. 15. *The Letters, Speeches, &c., of Lord Chancellor Bacon.* His numerous communications to the Royal Society may be seen in the *Philosophical Transactions.*

BIRD WILLIAM, an English composer, and one of the best organists of his time, was born about 1540, and died at London, 4th July 1623. He was appointed organist of Lincoln cathedral in 1563; and in 1575 he and his master Tallis were gentlemen of the chapel royal, and organists to Queen Elizabeth. Bird was the earliest English composer of madrigals, and some of his numerous sacred compositions are still much esteemed. Most of them were published during his lifetime under a patent from Queen Elizabeth, which secured to him and Tallis the sole right to print and sell music. Between 1575 and 1611 there were issued under this patent eight different collections of his works, with such titles as *Cantiones Sacræ; Gradualia, Psalmes, Songs, and Sonets*, &c. The vocal canon *Non nobis Domine*, generally attributed to him, is well known, and often sung. He also wrote a number of pieces for Queen Elizabeth's Virginal Book, and other similar collections. In his compositions there is a freedom and elegance rarely found in the music of his period. A full account of Bird's life by E. F. Rimbault is prefixed to one of his Masses, published by the Musical Antiquarian Society.

BIRDS

ANATOMY OF BIRDS.

In the consideration of the Anatomy of Birds, classification will be quite a secondary matter, and merely employed for the elucidation of internal structure. Some sort of grouping, however, is indispensable; and that is accordingly adopted, as the most convenient for the morphologist, which was first proposed by Professor Huxley,[1] with the introduction of certain modifications rendered necessary by the present writer's own researches—researches, it may be added, which have been carried on in constant communication with that investigator.

A little examination will show that the groups made by consideration of any, even the most important, morphological modifications, cannot be *superimposed upon* groups made by reference to the whole sum of the characters of the Bird. This may be easily explained. About half the known Birds, 5000 or thereabouts, belong, according to G. R. Gray, to Professor Huxley's group, the *Coracomorphæ*. These birds undergo a peculiar metamorphosis of the naso-palatal structures, and are called by Professor Huxley the *Ægithognathæ* on that account. Now all the *Coracomorphæ* have the ægithognathous palate, but so also have the *Cypselidæ*, or Swifts, which are placed by this author with the Humming-birds and Goatsuckers, both of which groups are simply schizognathous. Moreover, below the Passerine types, and only next above the Semistruthious Tinamous, we find the Hemipods, *Turnicidæ*, or *Turnicimorphæ*, and these have an ægithognathous palate. So also has another type, *Thinocorus*, which lies on the same low zoological level as the Hemipods. This latter bird is essentially a small Geranomorph, but it is below the true Cranes, and unites in its palate characters belonging to the Ostriches below it and the Passerines which ascend, zoologically, far above it.

The difficulty of applying this very valuable morphological grouping, and making it fit in with one that is more general and distinctively zoological (that is, having reference to every character, external and internal), does not take away anything of real value from it. To the anatomist such a mode of viewing the various types is perfectly natural, however hard it may be to satisfy the pure zoologist as to its great value. Certainly, the structures of the skull and face govern the whole body, as it were; every other part of the organism corresponds to what is observable there. Nor must it be forgotten that the true mode of studying any kind of creature is that of its *development;* and the head undergoes the most remarkable morphological changes.

In the following scheme we have added one new morphological group to Professor Huxley's classification. This group includes the Woodpeckers and Wrynecks, *Picidæ* and *Yungidæ*. Zoologically it forms the family *Celeomorphæ* (Huxley); its morphological term is *Saurognathæ* (Parker).

Every one who has laboured at the anatomy of this class must have been struck by its marvellous uniformity; almost countless numbers of species are found passing insensibly into one another, and differing in the slightest manner. The best modern zoologists are at times almost at their wits' end to know by what characters they may distinguish their genera and species. This has been well put by Professor Huxley (*Anat. of Vert. Anim.*) He says (p. 272)—"Though this class contains a great number of specific forms, the structural modifications which they present are of comparatively little importance, any two birds which can be selected differing from one another far less than the extreme types of the *Lacertilia*, and hardly more than the extreme forms of the *Chelonia*, do. Hence the characters by which the following groups" (see subjoined table) "are separated appear almost insignificant when compared with those by which the divisions of the *Reptilia* are indicated."

Morphological Classification of Birds.

A. The metacarpals not ankylosed together. The tail longer than the body.

I. Saururæ.

1. *Archæopterygidæ*.

B. The metacarpals ankylosed together. The tail considerably shorter than the body.

A. The sternum devoid of a keel.

II. Ratitæ.

a. The wing with a rudimentary, or very short, humerus and with not more than one ungual phalanx.

α. A hallux.

2. *Apterygidæ* (the Kiwis).

β. No hallux.

3. *Dinornithidæ* (the Moas).

4. *Casuariidæ* (the Cassowaries and Emeus).

b. The wing with a long humerus, and with two ungual phalanges.

α. The ischia uniting immediately beneath the sacrum, and the pubes free.

5. *Rheidæ* (the American Ostriches).

β. The ischia free, and the pubes uniting in a ventral symphysis.

6. *Struthionidæ* (the Ostriches).

B. The sternum provided with a keel.[2]

III. Carinatæ.

a. The vomer broad behind, and interposing between the pterygoids, the palatines, and the basi-sphenoidal rostrum (**Dromæognathæ**).

7. *Tinamomorphæ* (the Tinamous).

b. The vomer narrow behind; the pterygoids and palatines articulating largely with the basi-sphenoidal rostrum.

α. The maxillo-palatines free.[3]

i. The vomer pointed in front (**Schizognathæ**).

8. *Charadriomorphæ* (the Plovers).
9. *Cecomorphæ* (the Gulls).
10. *Spheniscomorphæ* (the Penguins).
11. *Geranomorphæ* (the Cranes).[4]
12. *Alectoromorphæ* (the Fowls).
13. *Pteroclomorphæ* (the Sand-Grouse).
14. *Peristeromorphæ* (the Pigeons).
15. *Heteromorphæ* (the Hoazins).
16. *Coccygomorphæ* (part), (the Goatsuckers).

[1] "On the Classification of Birds; and of the taxonomic value of the modifications of certain of the cranial bones observable in that class," *Proceedings of the Zoological Society*, April 11, 1867, pp. 415–472. This classification is somewhat modified in a later paper by the same author, in which a very masterly description is given of the Gallinaceous group (*Alectoromorphæ*, Huxley), "On the Classification and Distribution of the *Alectoromorphæ* and *Heteromorphæ*," *ibid.*, May 14, 1868, pp. 293–319. The same author repeats, in essentially the same form, the original classification in his *Anatomy of the Vertebrated Animals* (1871, p. 272). The materials from which the modified views here given have been taken are in a series of contributions by Mr Parker to the *Transactions of the Linnean and Zoological Societies* now (1875) passing through the press. For figures of the skeleton see Mr Eyton's *Osteologia Avium*.

[2] The keel is but little developed in *Strigops* (*Psittacidæ*), in *Didus* (*Dididæ*), and in *Aptornis* (*Rallidæ*).

[3] Professor Huxley here gives in a note two exceptions, namely, *Crax* and *Dicholophus*. The latter bird, the Cariama, is, however, as Mr Parker has shown, a low, gruiform, rapacious bird, having its maxillo-palatines united by suture, and being an example of a bird with *imperfect direct desmognathism*.

[4] With the exception of *Thinocorus*, see below.

17. *Trochilomorphæ* (the Humming-Birds).
    ii. The vomer truncated in front (**Ægithognathæ**).
18. *Geranomorphæ* (part), (the exceptional subfamily *Thinocorinæ*, Thinocorus).
19. *Turnicomorphæ* (the Hemipods).
20. *Cypselomorphæ* (the Swifts).
21. *Coracomorphæ* (the Passerines).
    iii. The vomerine halves permanently distinct, and the maxillo-palatines arrested (**Saurognathæ**).
22. *Celeomorphæ* (the Woodpeckers).
    β. The maxillo palatines united, either by coalescence with the ossified septum nasi; or, 2*d*, by meeting at the mid-line and forming a suture; or, 3*d*, in the fullest degree, by complete ankylosis of the right and left plates.
23. *Aetomorphæ* (the Birds of Prey).
24. *Psittacomorphæ* (the Parrots).
25. *Coccygomorphæ* (the Cuckoos, Kingfishers, and Trogons).
26. *Chenomorphæ* (the Anserine Birds).
27. *Amphimorphæ* (the Flamingoes).
28. *Pelargomorphæ* (the Storks).
29. *Dysporomorphæ* (the Cormorants).

The above scheme is a nail in a sure place; and on it, for the present, we may hang all that we know, or are learning, of the anatomical structure of this class of Vertebrates. That which relates to the *Carinatæ* must, however, be regarded merely as a *list* of Birds having a similar facial structure.

For the general ornithologist it is very suggestive and helpful, and will save him from looking merely on outward appearances; for the study of structure and development is looking into the heart of the matter.

The Skull.

To both the zoologist and the palæontologist an explanation of the *skeleton* will be of the greatest value, for the framework must of necessity be correlated to the nervous system, and also govern the development of the muscles. It will here form the first and the largest part of our work. And as all things in the skeleton are conformed to the modifications of the skull, and, moreover, as the skull is the most knotty problem to the morphologist, it will receive the attention due to its superior importance.

Instead of describing the adult skull, and then showing how it develops, it would seem to be better to follow the stages of its growth, and thus see the meaning of the parts, and what metamorphic changes take place to give it its adult characters. Space will not permit any detail of the general embryology of the Bird, but the skull will be described from the time when the rudiments of the chondro-cranium are first fairly visible, that is, about the fifth day of incubation.[1]

As the *Schizognathous* type of skull, such as is seen in the Fowl, is the simplest variety found in the *Carinatæ*, it will be the most convenient for comparison with that of the *Ratitæ* and the Tinamous (the *Dromæognathous* variety) below, and the *Desmognathous*, and other kinds seen in Birds above the *Gallinaceæ* in the zoological scale.

The Cranium of the Fowl—First Stage.—The chondrocranium may be seen at the end of the fourth and the beginning of the fifth day of incubation, although the cartilage has as yet but little consistence, its cells being imperfectly soldered together. The head of the skull at this stage still shows the "visceral clefts;" and it is bent upon itself by what is called the *mesocephalic flexure*. When the membranous roof of the skull and the brain are removed at this stage, the whole floor is not seen from above, the fore-part being bent under and looking backwards

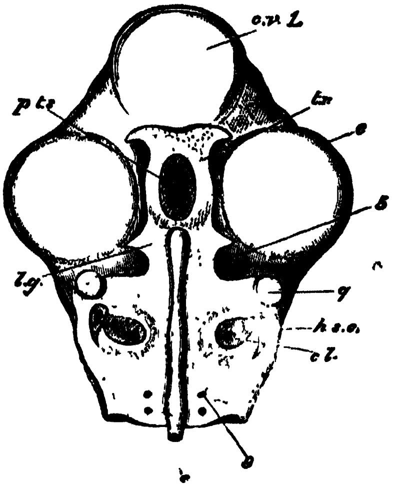

Fig. 1 Skull of *Chick* after four days of incubation, with head three lines long, first stage, from above, × 9 diameters. Most of the brain has been removed. c.v.1, first cerebral vesicle; *pt.s.*, pituitary space; *tr.*, trabeculæ cranii; *lg.*, lingula formed by junction of trabeculæ with the parachordal cartilages on each side of notochord (*n.c.*); *e.*, eye; *cl.*, cochlea, *q.*, quadrate cartilage; *h.s.c.*, horizontal semicircular canal; 5, foramen ovale; 9, hypoglossal nerve.

In the hinder half of the skull-floor, behind the eyeballs, we see a broad plate of tissue (fig. 1, *comp.* fig. 4, *i.v.*) which is passing rapidly from the condition of stellate cells into proper hyaline cartilage.

This plate is divided at the mid-line by a straight, somewhat beaded rod of soft indifferent tissue, which does not chondrify; it is rounded at its fore-end. This truly azygous part is the notochord (*n.c.*), or primary axis of the skeletal parts of the embryo; it lies directly beneath the neural axis, and is one of the parts earliest visible to the embryologist. The broad plate on each side is seen to be hollow, and to contain a pear-shaped diverticulum of the primordial ear-sac (*cl.*), which is planted, as it were, in the very substance of the basal plate, at its middle. The outer granular covering of the ear-sac becomes cartilage, and so does the basal plate—the "investing mass" of Rathke, the "parachordal cartilage" of Huxley.[2]

But the process by which these two separate morphological territories become converted into solid cheese-like cartilage is carried on blindly, as it were, and no distinction of parts is at present traceable; evident differentiation of morphological territories is often *late* in the higher types of vertebrata. The tissue which surrounds the spinal chord where this part passes into the brain is still soft; it will chondrify soon to form the occipital arch. The bulbous end of the notochord ends a little behind an oval membranous space or fontanelle in the skull-floor—the *pituitary space* (*pt.s.*). Near the end of the notochord, on each side, the cartilage suddenly narrows, for here we are in front of the impacted ear-sacs; at this part a bending of the narrow anterior end of the parachordal rounded notch (5) is formed, over which the trigeminal nerve passes. The anterior margin of the notch (afterwards formed into the *foramen ovale*) is formed by the cartilage; its actual extremity looks forward and outward, towards the eyeball. At present the bands which are continued forward, surrounding the pituitary space, are superimposed upon, and indistinct from, the ends of the parachordal cartilages; in the next stage they will be seen more distinctly. These flat bands of dense granular tissue are the *trabeculæ cranii* of Rathke (*tr.*), and they were supposed by him to be mere continuations of the parachordal bands, an error corrected some years ago by Professor Huxley. These little rafters of the cranium bend gently round the oval pituitary space; they then com-

[1] The whole development of the *Chick* is explained in a masterly and lucid manner by Messrs Foster and Balfour in their excellent work, *The Elements of Embryology*, London: Macmillan and Co. Part I., 1874. The description of the fowl's skull here given is principally from Mr Parker's paper, *Phil. Trans.*, 1869, plates 81-87, pp. 755-807. For a detailed description of the anatomy of birds, see Dr H. G. Bronn's *Klassen und Ordnungen des Thierreichs*, 1869, 6te Band, IV. Abtheilung, "Vögel."

[2] See Huxley on "Menobranchus," *Proceedings of Zoological Society*, March 17, 1874, p. 197.

pletely unite into a broad inter-nasal plate, which is bent over upon itself so as to appear on the under surface of the face.

The inter-nasal plate is arched and winged—the rudi-

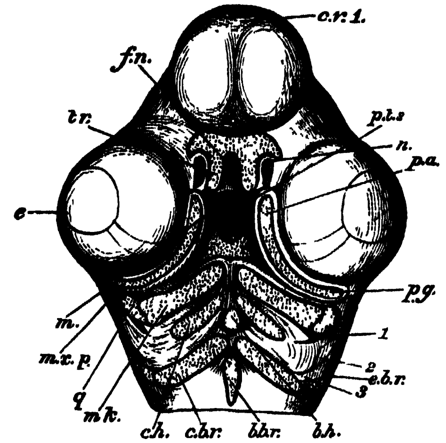

FIG. 2.—The same as fig. 1, seen from below. *f.n.*, fronto-nasal plate; *n.*, external nostril; *m.*, mouth; *mx.p.*, maxillo-palatine, containing pterygo-palatine bar (*pg. pa.*); *mk.*, Meckel's rod, or free mandibular bar; *c.h.*, cerato-hyal; *b.h.*, basi-hyal; *c.br.* cerato-branchial; *e.br.*, epi-branchial; *b.br.*, basi-branchial; 1, 2, 3, 1st, 2d, and 3d visceral clefts.

mentary condition of the nasal sacs, the apertures of which are seen beneath the arched part below (fig. 2, *n.*)

The trabeculæ, antero-inferiorly, become free again; these free extremities are the ventral ends of this the first *visceral arch;* they form the pith of the flat, emarginate rudimentary *neb.* This part is called the "fronto-nasal process" (fig. 2, *f.n.*)

On the sides of the face behind the mouth are seen slits (fig. 2, 1, 2, 3); these are the "visceral clefts," which are always developed in embryonic vertebrata. Between these clefts the tissue of the "mesoblast" is thickening into cartilaginous rods; these rods are the post-oral visceral arches, the rudiments of the lower jaw and hyoid bone. But beneath the eye is seen an arcuate bar of tissue more solid than its surroundings; this is the pterygo-palatine rod. It is developed in the maxillo-palatine process of the mandibular or first post-oral arch; it represents the bar of cartilage which, in the Frog, connects the mandibular suspensorium with the ethmoidal region.[1]

The *first* visceral arch, then, runs along in front of the parachordal cartilages; the trabeculæ cranii are its right and left *moieties.* The *second* arch can only be understood by reference to the development of the lower types of Vertebrata; for in the Shark, Skate, Newt, and Frog the pterygo-palatine portion is not a distinct cartilage, but runs forward as a *process* of the suspensory part of the lower jaw. But this early division of a visceral arch into an antero-superior and a postero-inferior bar is very constant in the next or *second* visceral arch from the *Skate* up to *Man.* Let it be remembered that the *cartilaginous* stage is the second; in the first stage the skeletal parts are membranous. They are formed of soft stellate cells in the mesoblast.[2]

At present the subocular pterygo-palatine bar is very little denser than the tissue in which it is imbedded, but the mandible itself is fast passing into cartilage. Already it is in two pieces, a suspensory piece (figs. 1 and 2, *q.*), and a free rod (*mk.*); the upper piece becomes the quadrate, and the lower, longer part the articulo-Meckelian bar. The processes of the tuberous upper piece are indistinct, but it is sinuous below where it articulates with the thick end of the free bar. These bars nearly, but not quite, meet in the rudimentary chin, the ventral end of the lower jaw. Properly speaking, the hyoid arch is composed of *two* visceral arches; but the term is now applied strictly to the first of these, namely, the second visceral, or the arch of the tongue. At present this arch has, with the one in front of it, its *antero-superior* piece quite soft; it, too, is *late* in its development. The two lower pieces (fig. 2, *c.h.*) form the skeleton of the tongue. They are the cerato-hyals, and between these is a small basi-hyal (*b.h.*) answering to the first basi-branchial of a Fish. The third post-oral arch is very similar, but it is larger, and its upper piece is already fast chondrifying. That corresponds to the first epi-branchial of a Fish, the lower piece to the first cerato-branchial, and the median wedge to the second basi-branchial.[3]

Cranium of Fowl—Second Stage.—In from twenty-four to thirty hours, or about the beginning of the sixth day of incubation, the chondro-cranium of the chick has undergone sundry and notable changes. A sectional view (fig. 3)

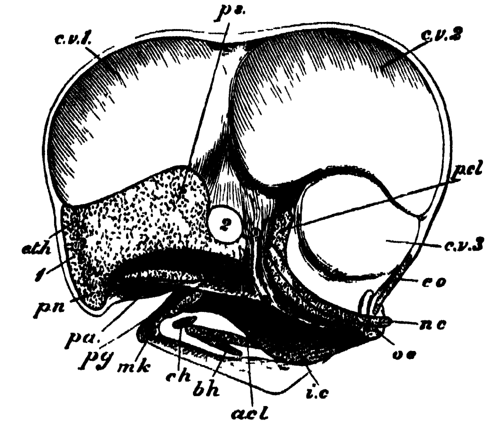

FIG. 3.—Head of *Chick*, second stage, after five days of incubation; length of head, 4 lines; × 6 diameters; a vertical section. *c.v.1*, *c.v.2*, *c.v.3*, 1st, 2d, and 3d cerebral vesicles; 1, 2, localities of first and second nerves (olfactory and optic); *pn.*, prenasal cartilage; *eth.*, ethmoid; *a.cl.*, anterior clinoid wall; *p.cl.*, posterior clinoid wall; *n.c.*, notochord; *o.c.*, occipital condyle (from this point to *p.cl.* the cartilage is parachordal); *e.o.*, exoccipital; *i.c.*, internal carotid artery; *pa.*, palatine; *pg.*, pterygoid region; *mk.*, Meckel's cartilage; *c.h.*, cerato-hyal; *b.h.*, basi-hyal; *p.s.*, presphenoidal region.

shows that the hinder and front cartilages, parachordal and trabecular, are applied to each other unconformably, the parachordal tracts rising high between the second and third cerebral vesicles, and forming the posterior pituitary wall, a shelving structure in which the axial skeleton ends.

A bird's-eye view of the hinder skull-floor at this stage (fig. 4) shows that the dorsal or hinder ends of the trabeculæ have opened out, like a pair of callipers, and that the out-turned ends of the parachordal cartilages are fused with the inner margin of these apices. The bud-shaped process, which has almost freed itself from the rest, opposite the bulbous end of the notochord, is the true apex of the first visceral bar, or trabecula; in the next stage it is far more distinct and instructive. Turning again to the vertical section (fig. 3), we see that the commissure of the trabeculæ, or inter-nasal plate,[4] has now become a high wall of cartilage, separating not only the nasal sacs, but also the eyeballs.

That part of the septum which now looks, not only downwards, but is also turned somewhat backward (fig. 3, *eth.*), will ultimately lie in the upper part of the nasal and frontal regions. A new thing has appeared, namely, an

azygous cartilaginous bud at the mid-line of the fronto-nasal process; it is about to become the axis of the beak, and will turn forwards and upwards. This is the prenasal or basi-trabecular cartilage, a notable morphological element *up* here, amongst the Birds, and *down* amongst the lower or cartilaginous types of Fishes. At the present it corresponds exactly to the state of the Green Turtle's skull (chondro cranium) at the time of hatching, and in that type it stops at this stage, not raising itself into a forth standing rostrum.

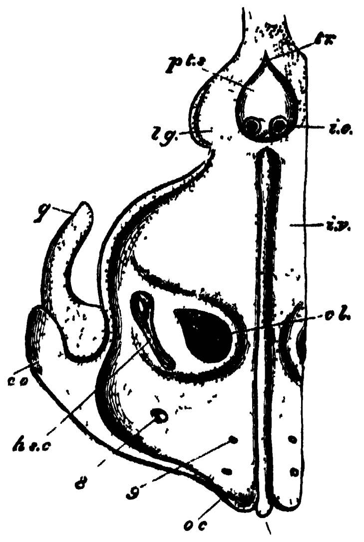

FIG. 4. Skull of *Chick* whose head was five lines long, more than half of bird's eye view, × 12 diameters. Lettering as above, with addition of *i.v.*, investing mass or parachordal cartil age, *i.c.*, internal carotid artery, 8, foramen for vagus nerve. Here the lingula (*lg.*) shows the apex of the trabecula externally.

The mouth, which in the first stage was a large four-sided cleft, with produced corners, and clean beneath the head, as in a Skate, is now a space, the axis of which points more forward than downward, a good step towards its eventual direction. The further development of the facial arches will be best studied in older specimens at the end of this, the second stage; but at its commencement there is wanted the condition of the *antero-superior* segment of the hyoid, or second post-oral arch. This has not been worked out in the Fowl's chick, but in an embryo of the House Martin (*Chelidon urbica*) corresponding to the stage given in our third figure as to development.

In this instance the quadrate and articular Meckelian cartilages have acquired very nearly their proper form (fig. 5, *q.*, *ar.*, *mk.*), the suspensorial part having a free for-

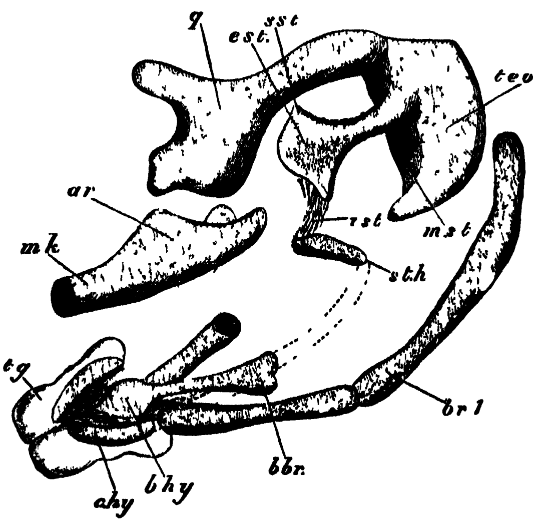

FIG. 5.—Facial arches of House Martin (*Chelidon urbica*), middle of incubation, × 20 diameters. *q.*, quadrate, with orbital process or "pedicle" in front, "otic process" behind, and articular facet below; *ar.*, articular part of mandible, *mk.*, Meckel's cartilage (cut through), *m.st.*, medio stapedial (the line from the letters only reaches *half way* to this bar), *s st.*, supra-stapedial; *e.st.*, extra-stapedial; *i st.*, infra-stapedial (soft), *st h.*, stylo hyal, *t e o.*, tympanic wing of exoccipital; *tg.* tongue, *c hy.*, cerato hyal; *b hy.*, basi hyal; *b br.*, basi-branchial; *br.* 1, 1st branchial or thyro-hyal.

ward and inward looking process, the "pedicle," and a backward turned process, the "otic process," articulating with the auditory sac (this is drawn as cut away in part, and only that which is conjoined to the occipital cartilage (*t.e.o.*) is given). Just below *and behind* the otic process of the quadrate, exactly where in riper embryos we find the *fenestra ovalis*, having fitted into it the elegant oval base of the "columella auris," there is in this instance a curious trowel of cartilage, continuous by the upturned end of its handle with the very substance of the ear-capsule. The solid sickle-shaped cartilage behind this is the "tympanic wing" of the exoccipital (*t.e.o.*) Here we have the wanting upper and anterior segment of the hyoid arch, corresponding to the separately developed pterygo-palatine bar, its "serial homologue." The blade or free end of the trowel is concave on the under side, and is thick above and at its margin on the outside; it is pointed above and below. A ligament connects the upper point with the ear-capsule behind the quadrate, and another tract of soft *indifferent tissue* reaches downwards to a small bar of cartilage, which looks backwards and a little downwards. This little cartilage (*st.h.*) is only connected with the distal piece (*c.hy.*) by fibrous tissue; it is the stylo-hyal, and corresponds to what is permanent in the Crocodile. The bar itself is the "medio-stapedial" (*m.st.*); it will soon segment itself off from the ear-capsule, bringing away with it an oval piece of the periotic wall; that oval part is the true stapes. The broad part of the "blade" is the extra-stapedial, and on it will be stretched the *membrani tympani*. It precisely corresponds now with that of that old Lacertian *Hatteria* or *Sphenodon*.[1]

The "stylo-hyal" will soon be conjoined to the extra-stapedial plate, and the (afterwards) chondrified band will be the "infra-stapedial"[2]

In a few hours the changes that have taken place in the chick's skull are very noticeable and important; these are recorded as the end of the second stage.

A side view of the chondro-cranium (fig. 6) the mem-

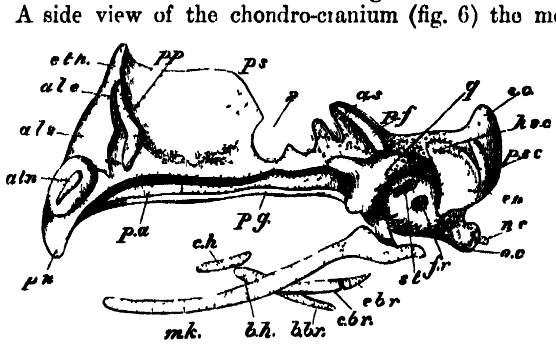

FIG. 6.—Skull of *Chick*, second stage, head 5 lines long × 6 diameters. Outer view, with brain and roof removed to show chondro cranium. Letters as in figs. 1-4, with the addition of *al n.*, alinasal cartilage, *al s.*, aliseptal, *al e.*, alethmoidal, *p p.*, pars plana, *a s.*, alisphenoid *p.f.*, post frontal (sphenotic region), *s o.*, super-occipital; *st.*, stapes; *f r.*, foramen rotundum, *p.s.c.*, posterior semicircular canal.

brano-cranium above the brain being removed, shows how fast the life-processes are moulding the embryonic head into the fashion seen in the adult; no trace of bone has appeared, save in the sides of the mandible. The roof of the skull never chondrifies, but is covered in by secondary bones. Like the skull of an adult Shark or Skate, the whole chondro-cranium is one continuous structure—all save the post-oral arches. The auditory mass is now environed by cartilage stretching over the back of the head—the occipital, and by wing-like growths that wall-in the bulk of the brain behind the eyes—the alisphenoid (*a.s.*) The high

[1] See Huxley "On the Representatives of the Malleus and Incus of the Mammalia in the other Vertebrata," *Proc. Zool. Soc.*, May 27, 1869, pp. 394-397, figs. 1-4.

[2] For a comparison of these parts with the *ossicula auditus* of the Mammal, see also Parker "On the Structure and Development of the Skull in the Pig," *Phil. Trans.*, 1874, p. 331.

orbito-nasal wall is one continuous plate of cartilage, seemingly only a crest upgrowing from the coalesced tract of the trabeculæ. The arched wings of this part, which we saw in the first stage, can be seen to be marked off into three regions—an aliethmoid (*al.e.*), an aliseptal (*al.s.*), and an alinasal (*al.n.*); in the latter is the external nostril, and dividing the eye from the nose is a flat partition, the *pars plana* (*p.p.*) Between the nasal openings and their curtains and valves, the prenasal cartilage (*p.n.*), still arcuate, is yet rising in front; whilst, behind and above, the great middle wall (*eth.*) terminates by a bud of cartilage, which marks the fore-end of the cranial cavity, and the groove on each side below this is for the nerve of smell (1). The oval pituitary space has become a neat round opening, through which the internal carotid arteries enter: it never chondrifies below, and has to be floored afterwards by secondary bone. The upper hyoid element (*st.*) has now freed itself from the periotic cartilage, bringing away so much as serves for the dilated dorsal end, and thus leaving an open window (*fenestra ovalis*), to which this forms the accurately fitted shutter. In front of this small cartilage, the quadrate (*q.*) shows almost its adult form, and the double lower condyle fits into a sinuous concavity on the end of Meckel's cartilage (*mk.*) This free bar—the mandible—sends backwards a posterior, and inwards an internal angular process. The later and feebler pterygo-palatine sickles are now formed internally of small thin-walled spheroidal, and externally of fusiform, cells of a larger size. They ossify before chondrification can take place.

Interposed between the skin of the palate and fauces below and the basis cranii above, is a thick mat of granular tissue, which does not, however, chondrify, but ossifies as the parasphenoid and basi-temporal bones.

Cranium of Fowl—Third Stage.—After about three or four days, that is, about the middle of the second week of incubation, the chondro-cranium has not only undergone great changes in size and form, it is also now beginning to become an *osteo cranium.* All that is cartilaginous has acquired a neat finish (figs. 7, 8); the occipital condyle (*o.c.*) is perfect; the super-occipital arch is complete (fig. 8, *s.o.*); and bone is forming in three places in the occiput (*n.c.*, *e.o.*), and the bone (*pa.s.*) which underlies the orbital septum has grafted itself upon the cartilage of the basi-sphenoidal region. That bone, the parasphenoid (*r.b.s.*), and the other investing bones, are now growing in the tissue between the skin and the cranio-facial elements; those that can be seen below are shown in figure 8, the remainder can be described in riper stages. The downward bend (not shown in the figure) of the prenasal rostrum (*p.n.*) is but gentle; this long spatulate continuation of the base of the orbito-nasal septum, the "basi-trabecular bar," or foremost keystone piece of the body, is now at its fullest height of growth, and ready to decline. It is now the accurate

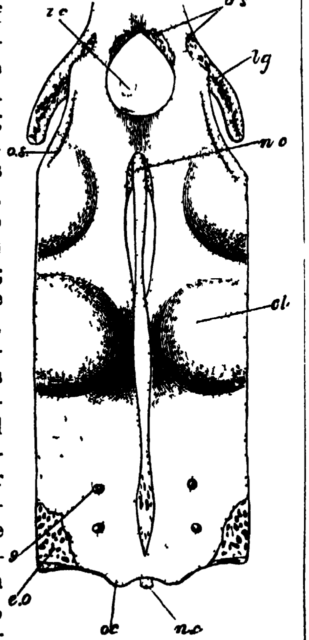

FIG 7.—Skull of *Chick*, third stage, part of basal region, from above, × 13 diameters *a s*, root of ali sphenoid *b s*, basi sphenoid The notochord (*n c*) is seen to lie in an open space in front the posterior basi cranial fontanelle—and to be bony behind; the bony matter is the rudiment of the basi-occipital.

counterpart of the axis of the cutwater of such Fishes as the Skate, Saw-fish, and Shark. Those who look for the under-

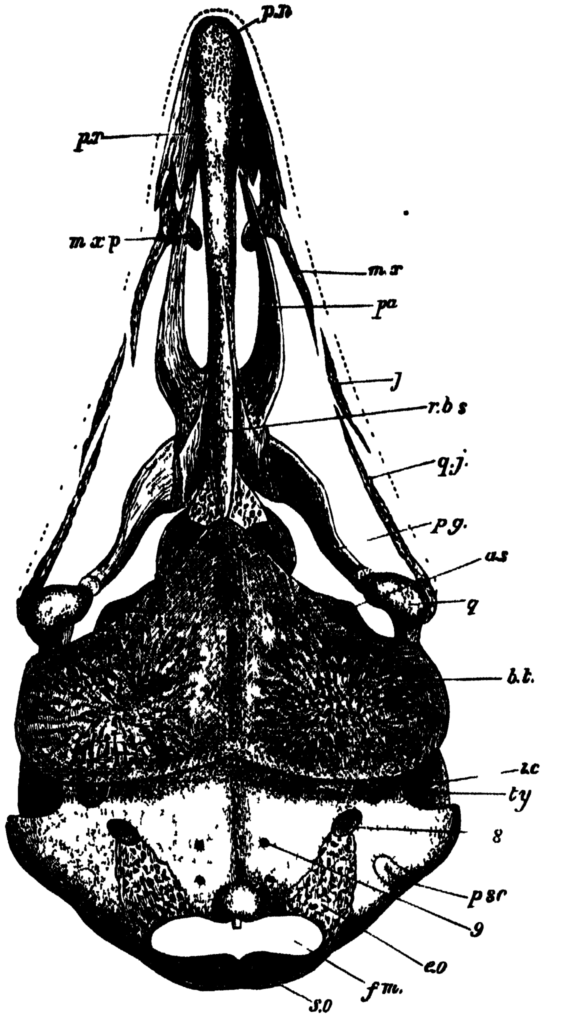

FIG 8 Skull of *Chick*, third stage, under view × 10 diameters Around the large prenasal cartilage *p n*, which, behind, runs into the septum nasi, are seen the premaxillaries (*px*) These are the commencement of a chain of splints running to the quadrate (*q*), viz, *mx*, maxillary *mx p*, its inner process, *j*, jugal, *q j*, quadrato-jugal. Within these are—*pa*, palatine, *pg*, pterygoid, *r bs*, rostrum of basi sphenoid (parasphenoid), this is spreading into the basi sphenoidal region, flanked by the linguiæ, and above and behind are the ali-sphenoids (*a s*) In the broad part are the following, viz, *b t.*, basi-temporals, *ty*, tympanic cavity *f m*, foramen magnum, *b e o*, the bony exoccipitals, *s.o.* super occipital Other letters as above.

lying *unity* of the various types may here see how fit this unpaired rod is to have modelled on it all kinds of beaks of Birds On this bar a tri-radiate patch of bone is formed right and left, leaving it as yet uncovered below, above, and at the fore-end. These are the young premaxillaries, and are bones that in most Birds, as in Osseous Fishes, overshadow and starve the upper jaw-bones, or maxillaries proper, so large, relatively, in most other types. Already they have each a palatine, a nasal, and a dentary process. The machinery of the first post oral is shown (fig. 8), all save the free mandible, which will be described in a more advanced stage. The quadrate (*q.*) is ossifying; the pterygoid and palatines (*pg.*, *pa.*) are ossified; they are very simple bars Between the premaxillary and the quadrate are bones that have been formed in the outer part of the "maxillo-palatine process" of the embryo; they are the feeble maxillary, with its ingrowing maxillo-palatine plate, and the still feebler jugal and quadrato-jugal (*mx.*, *mx.p.*, *j.*, *q.j.*)

On the mid-line a grooved style of bone, the rostrum of the parasphenoid, carries the rounded lower edge of the

inter-orbital septum, and has grafted itself upon the cartilage of the pituitary ring, causing it also to ossify. On each side, behind these new bony patches, a free tongue of cartilage is seen. These tongues are the apices of the trabecular bars. They are better seen in the partial view (fig. 7). Underflooring the fore-half of the main skull base, close behind the pituitary ossifications, the thick mat of sub-mucous tissue is fast becoming bony. There is a right and left squarish patch, very large and elegant; in the grooved mid-line a few osseous points are also seen, ready to grow right and left into the two plates, and to make them one. These are the basi-temporals (*b.t.*) They soon coalesce with the ossifying basi-sphenoid above, and they represent the handle of the dagger-shaped parasphenoid of the Frog.[1] The super-occipital region (*s.o.*) is still soft, and the exoccipitals do not reach to the condyloid foramina (9). They begin at the hole for the *vagus*, and run to the selvedge at the foramen magnum (8, *f.m.*) The kidney-shaped transverse condyle (*o.c*) has in its substance the diminishing notochord (*n.c.*), which, however, is better seen in the partial upper view (fig. 7, *n.c.*) This figure shows that the notochord has tried, as it were, to break up into three fusiform segments. The hinder of these is enclosed in an ectosteal sheath, which will affect with bony growth the neighbouring cartilage, right and left, to form the basi-occipital. The fore-part is narrower, and lies in an open space, the counterpart of the membranous floor ("posterior basi-cranial fontanelle"—Rathke), which lies behind the pituitary space in the Snake's embryo. On each side of the middle notochordal spindle are seen the elegant mammillary elevations caused by the enclosed *cochleæ* (*cl.*) The internal carotids (*i.c.*) are seen creeping through the pituitary hole, and on each side the ossification has been set up, which forms the true endo-skeletal basi-sphenoid. On each side of the posterior pituitary or clinoid wall, the cartilage is pinched in to let the great trigeminal nerves pass over; but two parts of intensest interest are seen on each side of these shallow notches. These are the apices of the trabeculæ (*tg.*), free-ended, curved tongues of cartilage, with dark cells in their interior, and fixed to the out-turned anterior ends of the parachordal cartilages, just where the new bony matter is seen. The meaning of these parts that make the pituitary region was not seen at the time by the author of the paper we are quoting (Parker "On the Fowl's Skull"); further research was needed, and his figures are of much greater value than his descriptions.

Cranium of Fowl—Fourth Stage.—At the beginning of the third week of incubation the chondro-cranium is not only perfect as to form, but it has also so much increased its bony territories as to make it very useful for comparison with *chondrosteous* skulls of the lower types. When every investing bone has been removed, we get such a structure as is shown (from above) in fig. 9. Here the cranial basin has a short and fenestrate floor, and doubly-winged sides, which are gently scooped above, and form a pair of symmetrical ledges on which the widest part of the brain rests; whilst the floor dips much lower down, where the medulla oblongata and the pituitary body rest. The scooped fenestrate alisphenoids (*a.s.*) look inward, but fail to reach the median line by a great space, which space is filled in by no *orbital wings*, such as we should see in a Lizard, Turtle, or Mammal. The whole orbital region is, in the skull, a steep wall, having a retral crest on its fore-part, this crest being the rudiment of the large sheet of cartilage (*tegmen cranii*), which is thrown over the brain in the young Salmon.[2] This wall (*p.s.*), this crest, and the elegant cartilaginous awning in front of the crest, containing valves

[1] See article AMPHIBIA, vol i. p. 753, fig. 5, *p.s.*

[2] See "Salmon's Skull," *op. cit.*, plate 4, fig. 2, *t.cr.*

and folded curtains of most cunning construction (see figs. 10 and 11)—all these have grown out of that inter-nasal

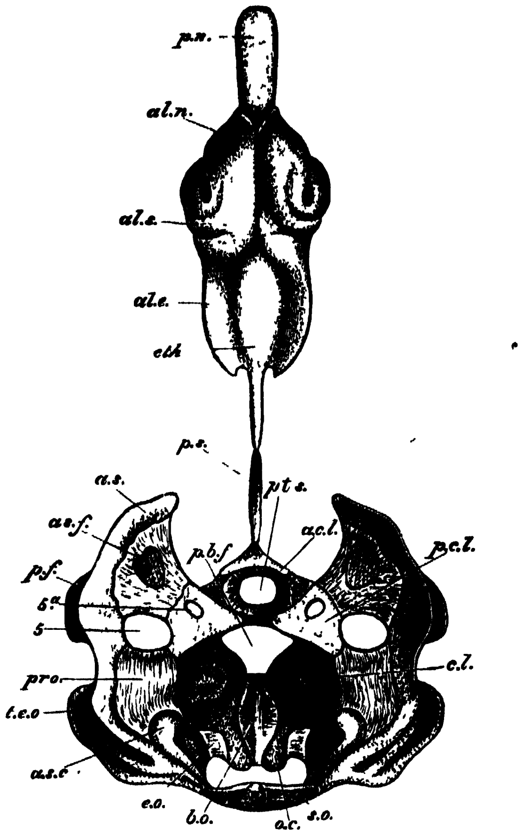

FIG. 9.—Skull of Chick, fourth stage, head nearly 1¼ inch long, beginning of third week, × 4 diameters. The additional letters are—*a.s.f.*, alisphenoidal fenestra; *p.b.f.*, posterior basi-cranial, fontanelle; *pro.*, prootic bone; *a.s.c.*, anterior semicircular canal; *t.e o*, tympanic wing of exoccipital; *b.o.*, basi-occipital; *5a*, foramen rotundum; *5*, foramen ovale.

plate formed by the trabeculæ as their commissure (figs. 1 and 2, *tr.*)

Morphologically considered, these are added and distinct elements, but their differentiation from the trabeculæ can not be seen well until now, and even now it is imperfect. The leafy coverings of cartilage are seen to dip down on each side of the prenasal spatula in front, and the cartilage at this part forms a coiled, valvular nose-lid—the "alinasal region." From this, in its inside, there hangs a curtain, all of cartilage (fig. 10, *n.tb.*), the "alinasal turbinal." It curves towards the septum, and then turns upwards below to become parallel to the inturned nasal wall (*l.n.w.*) Behind the alinasal comes the aliseptal region (*al.s.*); and when cut across at the notch behind it and the hinder part of the roof, it shows a doubly-coiled outgrowth, the "inferior turbinal" (fig. 11, *i.tb.* The hinder region or "aliethmoid" is the true olfactory region; the roof suddenly turns inward, and is coiled upon itself, so as to form the bagpipe-shaped upper turbinals, whose swollen faces look inwards to the mesethmoid. Behind their inturned part they send down a cartilaginous curtain, the *para plana*, or antorbital plate, the fore-face of which

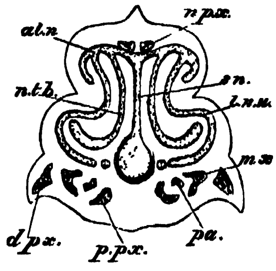

FIG. 10.—Skull of Chick, fourth stage, a transversely vertical section through the external nostrils, × 8 diameters. *s.n.*, septum nasi, *al.n.*, alinasal; *n tb.*, alinasal turbinal; *l.n.w.*, lateral nasal wall; *n.px.*, nasal processes of premaxillaries; *d.px.*, dentary processes of the same; *p.px.*, palatine processes of the same; *pa.*, palatine; *mx.*, maxillary. On each side of the thick base of the septum the nasal nerves are seen.

does not develop any obvious "middle turbinal" as in Man.

The differentiation of distinct morphological regions, which did not become obvious in the *membrano-cranium*, can now be seen to some extent in the well-developed cartilage. As in the *Ratitæ*, the orbito-nasal septum was, in the second stage, a continuous sheet of cartilage.[1]

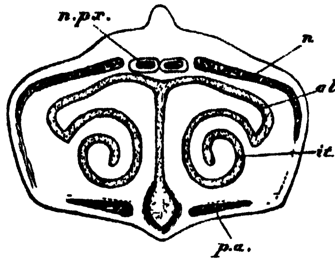

FIG. 11.—Another section from the same *Chick*, further back, × 8 diameters. *i.tb.*, inferior turbinal; *al.s.*, aliseptal; *n.*, nasal bone.

Looking upon the trabeculæ as the first facial arch, correlated to and supplied by the orbito-nasal nerve, we see why there should be a segmentation of this uppermost and foremost part of the face into a suspensorium and a free arch, such as is seen next behind in the mandible.

This segmentation has commenced, and, oddly enough, that part of the trabecular commissure which will be absorbed has not lost its original flap-shape (see fig. 12, *c.f.c.*, *s.v.l.*) The hour-glass-shaped window here formed by metamorphic action will become a notch in a day or two, and the flat region of the trabeculæ will be absorbed. Thus we get the Tinamine stage;[2] for in that intermediate form between the Ratite and Carinate types—the Tinamou—the metamorphic processes are stayed midway, and the bird is a native so to speak, of the Struthio-Gallinaceous "marches." Beneath the retral ethmoidal spike is seen the olfactory groove (1.); whilst in front of the cranio-facial fenestra (*c.f.c.*), the orbito-nasal nerve (*n.n.*) grooves the septum, gets bridged over by it, and creeps down to its own proper facial bar—the trabeculæ. And the result of the metamorphosis in this Carinate bird is the formation of a pear-shaped fenestra (*i.o.f.*) between the eyeballs. This window was not cut out by Nature in a fit of economy (as the mere teleologists vainly speak), but is a fairly commenced separation of the common crest of the coalesced trabeculæ from the ethmoid forwards and the presphenoid behind (*p.e.*, *p.s.*)

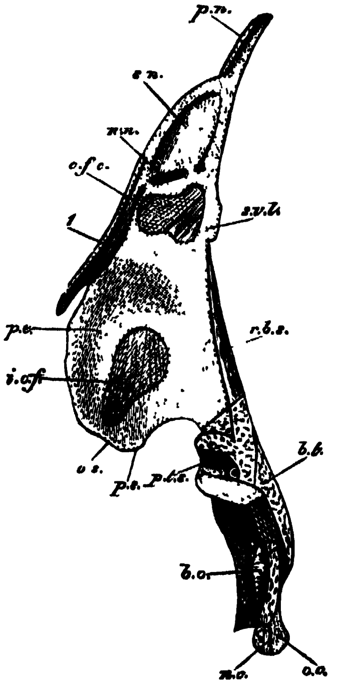

FIG. 12.—Axial part of the same skull, × 4 diameters. The new letters are *n n*, groove for nasal nerve; *c.f.c*, cranio-facial cleft, *s v.l.*, super-vomerine lamina, *p e*, perpendicular ethmoid; *i.o.f*, inter-orbital fenestra; *o.s.*, orbito-sphenoid.

The notch behind the cartilaginous frame of this window is formed by membrane into the optic foramen. A line drawn horizontally along the base of the fenestra, and another vertically to the upper margin of its narrow end, would mark out the starved presphenoid, without *alæ*, of this bird; for the mesethmoid and the basi-sphenoid (*p.e.*, *b.s.*) meet below the fenestra. Underneath the inter-orbital plate the parasphenoid balk (quite distinct) is seen, and underneath the basal bones the basi-temporal slab (*b.t.*) Turning again to the bird's-eye view (fig. 9.), we see that the notochord is now enclosed in a spearhead-shaped bone, the basi-occipital (*b.o.*) It is ridged above by the enclosed notochord, and, behind, the swelling halves of the condyle (*o.c.*) are seen. This basal bone is truncated in front, and forms the hinder margin of the wide rounded "posterior basi-cranial fontanelle" (*p.b.f.*) On each side are the exoccipitals (*e.o.*), and, above, the perfected occipital arch has a pair of super-occipitals (*s.o.*) as in man. The outer occipital region is grooved to receive the investing bones, and has tympanic wings to enlarge and protect that cavity. On each side of the fore-part of the basi-occipital is seen the cochlea (*cl.*); and in the ledge above the main periotic bone, the prootic (*pro.*) is largely spreading (the two lesser ossicles are appearing, but will be better shown in the next stage). The foramen ovale (5) is very large; it is bounded behind by the prootic, and in front by the alisphenoid (*a.s.*) This "great wing" has a large central fenestra, round which the bone has crept. In somewhat younger specimens this bony matter was in *two patches*, one above and another below the fenestra. The same thing may be seen in arboreal birds, as the Common Sparrow.

The stem of the alisphenoid almost meets its fellow-process over the posterior clinoid wall (*p.cl.*) In the stem is seen a "foramen rotundum." Outside, the alisphenoid has a thick, secondary, post-frontal (*sphenotic*) wing (*p.f.*) The round pituitary space is walled in with bone. Its secondary parasphenoidal floor has been removed. We reserve a description of the fast-growing roof bones for the next stage, when they are most instructive for comparison with those of Fishes and Reptiles.

Cranium of Fowl—Fifth Stage.—In a day or two after

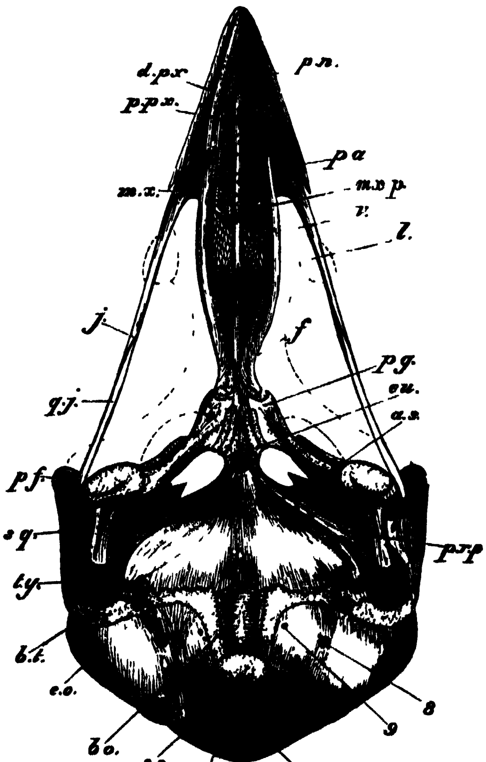

FIG. 13.—Ripe *Chick's* head, 1¼ inch long; lower view, × 3 diameters. The additional letters are *v.*, vomer, *l.*, lachrymal; *f.*, frontal, *eu.*, eustachian opening; *pr.p.*, posterior pterygoid processes; *sq.*, squamosal.

[1] See Parker "On Ostrich Skull," *Phil. Trans.*, 1866, plate 7, fig. 2, *p.e.*, and plate 8, fig. 10, *p.e.*

[2] "On Ostrich Skull," plate 15, fig. 8, *s.n.*, *p.e.*, *c.f.c.*

hatching, the skull of the chicken is excellent for comparison; as in Cattle, so in the Fowl and its relations, "their young ones are in good liking" as soon as they appear; hence they are strong in bone and sinew very early, the growth-processes taking place rapidly.

The under view (fig. 13) shows, behind the orbits, a strong cranial box. Synchondroses of the remainder of the chondrocranium divide the endo-skeletal bone-territories; and that organic attraction which causes the perfect correlation of the shallow with the deeper layers of the mesoblast, has given us here bony encasements, that not only fill in what was wanting in the chondro-cranium, but also overlie and double the strength of the ossified cartilage itself. All is neat and finished now, and now is the nick of time in

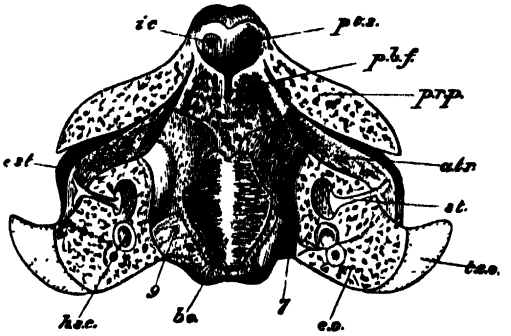

FIG 14.—Horizontal section of skull base of same *Chick*, × 4 diameters *a.t.r.*, anterior tympanic recess; *st.*, stapes; 7, portio mollis passage (meatus internus).

which can be seen most of the sutures, so soon to be obliterated by the almost universal ankylosis that takes place afterwards—a process by which Nature, in the Bird, rapidly fills in nearly all her footprints. Here she is as hard to bind as Proteus himself; and the morphological worker is often sore bestead to catch all the transformations. If the chick were to retain throughout life its present form of face, it would much resemble a Hemipod. We have seen how its skull becomes metamorphosed from a lower into a higher and a still higher type day by day.

This basal view shows that the bony pieces of the occipital arch are fast forming a strong ring, after the manner of a vertebra. The keystone piece (*s.o.*) is now one bone, with the remains of the suture above. The notochord still exists in the basal piece (*b.o.*), and is seen in the condyle, the dimple of which is caused by it. The basi-temporal plate (*b.t.*) is now a low triangle, with its base behind; the base is, as it were, gnawed, the jagged edge joining the overlying spheno-occipital by a squamous suture. This thick plate is emarginate in front, below the meeting of the eustachian tubes (*eu.*), and this notch is the mark of the original symmetry of this double bone. Grooved gently at the mid-line, the basi-temporal is mammillate on each side, these elegant swellings being due to the cochleæ that are encysted in the ossifying cartilage above. Behind, it is eared, and over these ears the internal carotids creep as they seek the pituitary space ready to form the "circle of Willis." The bone above and in front of the basi-temporal is a compound of the *rostral* parasphenoid and the proper basi-sphenoid. Altogether, this is a very extensive and multiform element. Directly in front of the basi-temporal it is scooped at the meeting of the eustachian tubes—diverticula of the first visceral cleft. In front of that part the rostrum is soon a free structure, grooved for the interorbital septum; but behind and above the basi-temporal the bony mass is all one, and it has an upper and a lower wing on each side behind the strong wall which it has built around the pituitary well. The upper of these wings are ossifications of that cartilage which we saw was formed by coalescence of the *sub-apical* part of the trabeculæ with the fore-end of the parachordal plates.

The large posterior basi-cranial fontanelle has now become the deep chink which exists as a ditch between these post-pituitary banks (fig. 14, *p.b.f.*) On the upper surface the chink reaches the basi-occipital; in the horizontal section (fig. 14) it is cut away behind.

The lower and outer pair of wings of the basi-sphenoid are very large (figs. 13 and 14); they build, on each side, the anterior tympanic recess (*a.t.r.*), and their starting point of growth is from the free apices of the trabeculæ, which are thus *feathered* with these large coiled laminæ of periosteal bone that enclose another diverticulum of the first visceral cleft, which lies over the eustachian passage.

Close in front of the eustachian groove the soldered part of the rostrum widens into a pair of projections, and, upon these, obliquely placed facets of cartilage are attached for articulation with counterpart cartilages on the pterygoid bones (*pg.*)

These perfectly distinct cartilages are the result of a peculiar metamorphosis of the outstanding (basi-pterygoid) spurs of the trabeculæ. In the *Ratitæ*, as in Lizards and Serpents on the one hand and Mammals on the other, these *external pterygoid* plates or processes are a direct outgrowth of cartilage, the posterior conjugational spurs that grow out for union with the pterygo-palatine arcade.[1] Like the subdivision of the ethmo-trabecular wall, this segmentation of originally continuous cartilage is of the highest morphological importance. Several other things of this kind will be found in this class, where the Vertebrate pattern has been specialized and metamorphosed to its highest degree, as if to produce types that should be as *imagines* in relation to the forms beneath them. The remainder of the rostrum just runs, pointed, to the edge of the cranio-facial cleft (fig. 16, *r.b.s.* to *a.p.*) In front of this notch the septum nasi is seen, narrow and rounded, and it terminates below in the starving prenasal (*s.n.*, *p.n.*) Around and in front of that rod the now single premaxillary clings; it has its under surface grooved to the end, where that rod lay, its sides developed into the sharp dentary region (fig. 13, *d.px.*), and its under part growing backwards as two nearly parallel bands, the palatine processes (*p.px.*), that articulate with the palatine bones (*pa.*) These latter bones run backwards in the same gently diverging manner, and then curve inwards to be tied the one to the other, before they bend outward again, foot-like, to articulate with the pterygoids (*pg.*) These palatines are very simple; they give off from their main bars merely a scooped lamina, growing towards the skull base, becoming the ethmo-palatine in front; and this part articulates with a splint of the trabecular arch, the small styliform vomer (*v.*), which is notched behind, bluntly pointed in front, and primarily azygous.

The pterygoids (*pg.*) are stout little bony mallets, with a pad, as if of leather—the cartilaginous articular meniscus. Where each bone glides on the similarly padded trabecular region these facets look upwards and inwards. The end of the palatine is articulated by strong fibres to a sinuous notch on the fore-end of the pterygoid. This notch is bounded by the basi-pterygoid facet below, and by a stunted "meso-pterygoid process" above, which rides over the palatine. It is arrested in the *Gallinaceæ*, and never becomes segmented off (see below). The hinder end of the pterygoid is scooped below to articulate with the counterpart knob on the front face of the quadrate. A joint cavity is formed here. Above that joint, and looking upwards and forwards, is a very stunted "epi-pterygoid" process, which clings to, and is strongly strapped upon, the quadrate by fibrous tissue.

---

[1] See *Phil. Trans.*, 1866, plate 7, fig. 4, *a.p.*; and *ibid.*, 1874, plate 34, fig. 2, *e.pg.*

The large quadrate bone (figs. 13 and 15, *q.*) has its free pedicle or orbital process still soft above. Its otic

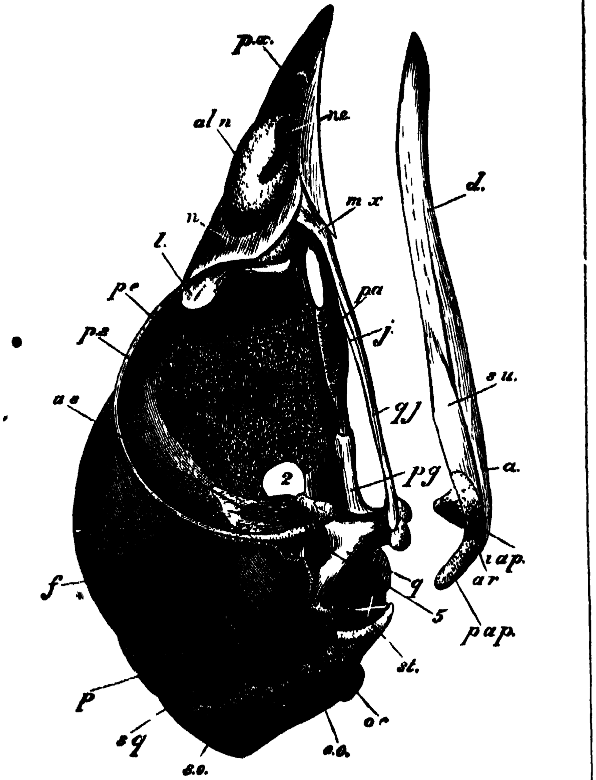

FIG 15.—Same skull, side view, × 3 diameters. Letters as above, with the addition of—*p*, parietal, *d.*, dentary, *su*, surangular, *a*, angular, *p.a.p.*, posterior angular process; *i.a.p.*, internal angular process; *ar.*, articulare.

process has a larger rounded head for the squamosal (*sq.*), and a lesser rounded head for the prootic within. In front of the otic process is a sort of trochanter or spur. Below, the articular facet is somewhat divided, by a shallow fossa, into an outer larger and an inner lesser facet. The otic process passes through the front of the tympanic cavity (first cleft), and becomes involved in the membrane thereto attached, namely, the membrana tympani. It was mistaken by anatomists of the last generation for the true tympanic bone. Behind this bone (see fig. 13) there are seen two holes, the inner of them leads to the auditory fenestræ (ovalis and rotunda) and the outer is the opening into a gallery which communicates, by means of diploë, with one on the other side. These are the "upper tympanic recesses," and have their counterparts in the Crocodile. Besides the pterygoid and palatine, in that part of the mandibular arch which is folded over the mouth, —for the first post-oral enfolds itself to make all the lower and much of the upper jaw,—there are in the outer part of the maxillo-palatine process three bones formed on each side, as we have seen.

The first of these is the bony *ichthyic* maxillary (*mx.*), with a bony foot, that grows inwards and backwards in a falcate manner, to articulate with the sides of the fore-end of the vomer. These are the maxillo-palatine processes (*mx. p.*) Behind the maxillary, overlapping its jugal process, is the styloid jugal (*j.*); and behind this, and overlapping it, the quadrato-jugal, which is hooked to fit in the side of the base of the quadrate behind (*q.j.*, *q.*) There is a small joint cavity at this place.

The side view (fig. 15) illustrates the above description; but it also shows much that is not visible below. The section (fig. 16) helps us still further.

The roofing bones are now well seen; the largest of these are the frontals (*f.*), which form the upper crescent of the large circle of the eye. They flatten in front, where

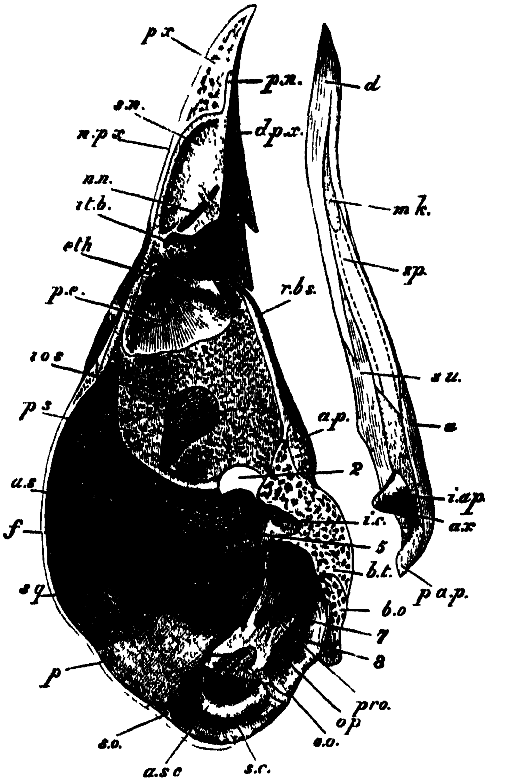

FIG. 16.—Longitudinally vertical section of the same skull, showing axial parts, cranial cavity, and inner view of mandible, × 8 diameters. *i.o f.*, inter-orbital space, or "fenestra," *a.p.*, anterior pterygoid process, or "basi-pterygoid;" *op.*, opisthotic; *a s.c.*, anterior semicircular canal; *s.c.*, sinus canal; *sp.*, splenial bone. The small bony centre between the prootic (*pro.*) and the super-occipital (*s.o.*) is the epiotic.

they are overlapped by the nasals and nasal processes of the premaxillaries (*n. px.*)—a peculiarly ornithic character amongst the higher vertebrata. The orbital rim is very neat and perfect; the main part of the bone, covering the *hemisphere*, is a convex radiating scale. Inside the orbit the bone sends inwards a thin scooped orbital process (*f.*), on whose convex surface the sloping brain rests. This fails to invest the fontanelle, and the orbito-sphenoids, as yet, are not. The somewhat oblong and also convex parietals (*p.*) stop up the gap as far as to the occipital arch; they are much smaller than the frontals. Both the parietals and frontals are flanked and in some degree overlapped by the squamosals (*sq.*), which are more irregular in shape than, but are fully as large as, the parietals. Half the inner face is seen within (fig. 16, *sq.*); the whole upper edge behind is hidden in this view, and much of the lower part, which forms a strong eave over the huge ear-mass. The lower edge has a cup for the quadrate main head. On the outside (fig. 15) there is to be noticed a variable cartilaginous tract; it takes in all the elegant crescentic tympanic wing of the exoccipitals (*t.e.o.*), and also runs in front of and between the ex- and super-occipitals (*e.o.*, *s.o.*) Between the two bones is the posterior opisthotic region; in front of the exoccipital is the epiotic region. From the inside the imbrication of the cranial and auditory bones is seen to be very regular and remarkable. Running round and across, behind and below the posterior margin of the frontal, we see the fenestrate alisphenoid (*a.s.*) underskirting the orbital plate of the frontal, then the hollowed inner face of the squamosal, and behind and above that the scooping of the parietal. Below the same, and also behind it, we have—above, two bones, the prootic in front

and the super-occipital behind. But the latter takes in all the breadth behind, whilst below the prootic are two, the upper the smaller; the lesser bone is the opisthotic, the larger, rounding the foramen magnum at its sides, is the ex-occipital (*op.*, *e.o.*) These are infero-lateral elements. Below the whole are the basi-sphenoid and the basi-occipital, both of them underfloored by the basi-temporal (*b.o.*, *b.t.*) So much tilted backwards is the auditory mass that the crown of the anterior canal (*a.s.c.*) is imbedded in the super-occipital. In a Lizard, Snake, or Turtle that part would be first enclosed in a separate epiotic bone, which would be soon confluent with the super-occipital. But in these high *Sauropsida* the epiotic is a small, *late* centre, formed behind the commencement of the anterior canal in the front part of the recess in which the "flocculus" lies. Also the opisthotic is small, but is distinct for three or four months; it is a wedge of bone, flat-faced within, forming a straight suture with the hind edge of the prootic, and externally runs as a fine thread of bone between the two fenestræ of the labyrinth. We do not see this bone behind until afterwards, and it soon coalesces with the exoccipital, first with it and afterwards with the prootic, as in Lizards and Snakes.[1] After the elements of the chondrifying cranium have run into each other, the enclosed ear organs, by their copious growth, and also by their having many diverticula, such as the cochlea and canals, trespass on neighbouring territories, so that whilst the cochleæ burrow into the parachordal region, the semicircular canals find room in the occipital arch.

In the Osseous Fish ("Salmon's Skull," *Phil. Trans.*, 1873, plate 5, fig. 8, *sp.o.*) there is a large bone called the "post-frontal" by Cuvier; in the Bird it often occurs, and looks like a secondary wing on the great sphenoidal wing (alisphenoid). In the Fish it covers the ampulla of the anterior canal; in the Bird it is in front of it and of the whole labyrinth. This bone, the "sphenotic," is ossified at the time of hatching.

The anterior sphenoidal region is all soft as yet (figs. 15 and 16, *p.s.*); and the great mesethmoidal wall (*p.e.*) covers only a third of its own proper territory. It now reaches to *the notch*; nearly to the roof also, but not to the para-sphenoid. The cartilage it is ossifying is continued as an isthmus connecting the parts behind and in front of the notch (cranio-facial hinge). Through this notch (fig. 16, *n.tb*) we see the swollen upper turbinal; and the nasal canal and bridge for the fore-part of the trabecular nerve is seen near the hind margin of the steep and well-formed septum nasi (*s.n.*) which has projecting from it the lessening rostrum (*p.n.*) Bridging over the notch, and let into the fore-edge of the frontal, are the never-coalesced nasal processes of the premaxillaries. *Outside* these, on each side (never in the middle in a Bird), are the nasals (fig. 15, *n.*) They are curious twisted bones, two-bladed in front to bind round the alinasal cartilages (*al.n.*) and outer nostril (*e.n.*); behind, they twist a little downwards the inner edge of their flat end. Tied by fibres to the side of the narrowed end of the frontal, and to that part of the nasal which is imbedded into it, is the lachrymal (fig. 15, *l.*) Its main part is the super-orbital, and this sends downwards a facial process, narrow and sigmoid. Within the lachrymal is the pars plana (*p.p.*), a subquadrate curtain, which is persistently cartilaginous in the Fowl, whose nasal labyrinth, unlike that of many birds, scarcely ossifies at all, except the main dividing wall, the perpendicular ethmoid, which always early becomes solid.

The free mandibular bars are now continuous at their fore or lower end; the long and strong dentaries (figs. 15 and 16, *d.*) early coalesce. In front they cover the attenuating Meckel's cartilage (*mk.*); this, however, grows on behind, and its inner process (*i.a.p.*) is ossifying as the "articulare," the only endo-skeletal bone in the mandible. Behind, outside, and a little within, we see an upper and a lower splint, the surangular and the angular (*su.*, *a.*), and on the inner side, further forwards, the oblong splenial (*s.p.*); but in this bird there has not been found a "coronoid," common in certain groups of Birds, besides Snakes, Lizards, and Crocodiles. In this and in other things the Fowl is often found wanting as to special elements.

The changes in the hyoid arch can be left until we come to the adult stage.

Cranium of Fowl—Sixth Stage.—This stage, which is

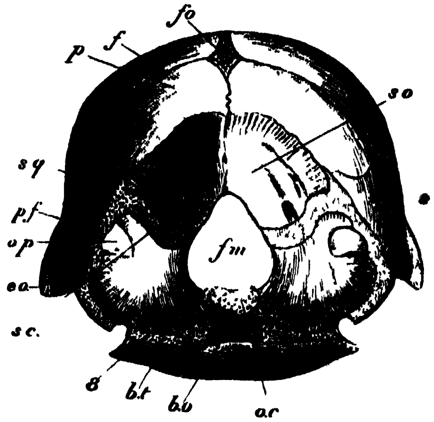

FIG. 17.—End view of skull of a *Chicken* three weeks old, sixth stage, × 8 diameters. Here the opisthotic bone appears in the occipital region, as in the adult Chelonian. Letters as above; *s c.*, the opening of the sinus-canal.

that of chickens less than a month old, is introduced to show the occipital region from behind (fig. 17). This end view shows much that is ornithically characteristic. The subject was a somewhat starved chicken, whose retardation of growth caused a lingering of the ankylosis, which so soon removes all landmarks. Even now the great fontanelle, or membranous roof of the basin-like chondro-cranium, is barely covered by the still scant frontals and parietals (*f.*, *p.*); their flanking by the big squamosals (*sq.*), and the projection beyond these of the sphenotics, are well shown. A wholly cartilaginous epiotic region is still seen; it runs also inwards to the foramen magnum (*f.m.*), and still skirts the tympanic ala (*e.o.*) But on the upper and outer edge of the exoccipital a small plot is taken from the great exoccipital. This is the appearance through the cartilage of the opisthotic (*op.*); and this represents the permanent condition of the occipital arch in the *Chelonia*, which shows a free posterior face of the opisthotic above and outside the exoccipital. This view also shows how the skull is double-floored by the addition of the basi-temporal slab to the ossifying chondro-cranium (*b.t.*, *b.o.*)

Cranium of Fowl—Seventh Stage.—In chickens two months old, a section of the skull shows all the sutures except those lost by early fusion of the three para-sphenoidal elements with the compound basi-sphenoidal ossifying cartilage. The periotic elements are all distinct, not only from each other, but also from their surroundings (*Phil. Trans.* 1869, plate 85, fig. 1.) The bony orbito-nasal wall (perpendicular ethmoid) has grown by metamorphosis of the cartilage up to, and somewhat over and under, the inter-orbital fenestra; thus half of this large septum is bony. There is no osseous presphenoid, but instead of the true orbito-sphenoids two osseous centres have appeared on

[1] The nomenclature of these parts is wrong in Mr Parker's paper on the "Fowl's Skull," *Phil. Trans.*, 1869; but he named their elements correctly in his former paper on the "Struthious Skull," *ibid.*, 1866. Researches into the growth of the Reptilian skull have helped to correct the error. He has found a true "pterotic" in the Sparrow-Hawk (*Monthly Micros. Jour.*, Feb. 1, 1873); that was the name given by him to the fowl's epiotic, whilst the latter name was applied to the posterior face of the opisthotic.

the post-orbital fontanelle, the foremost being the smaller bone; these help the orbital plate of the frontal to cover the eyeball with bone. In front of the doubly notched ethmoidal wall the face is connected with the skull by a narrow band of cartilage, which is never quite severed in this type. Thus the fore-face lifts on the skull in harmony with the depression of the mandible, by means of the elasticity of the parts, for, as we have seen, the firm splints above—nasals and nasal processes of the premaxillaries—are let into the frontal by their fibrous, lathy ends

Cranium of Fowl—Eighth Stage—Chicks Three months old.—Many sutures still remain at this stage, but those between the occipital and periotic elements are fast filling up (*Phil. Trans.*, 1869, plate 85, figs. 4–7, p. 794). We must refer the reader to the work above cited for the details; no stage shows the exquisite architecture of the ornithic skull more lucidly than this. The synchondroses are reduced to fine lines or sutures, and the *size* of the object is of great importance, as tending to make a difficult study easy to the observer.

Cranium of Fowl—Ninth Stage.—In chickens of the first winter, eight or nine months old, nearly full-sized, but yet succulent even in their skeleton, many things are to be observed (*op. cit.*, plates 86, 87, figs. 1–3, p. 795).

On the roof the sagittal suture is only obliterated in the parietal region, and the super-occipital still retains an upper notch. The occipital and auditory regions have entirely coalesced—the opisthotic with the exoccipital first, and then with the prootic; but the little epiotic seems to melt into the common mass of the ankylosing super-occipital and prootic, without any precedence either way. All the sutures across the cranio-facial hinge are still visible, namely, those made by the frontals, lachrymals, nasals, and nasal processes of the premaxillaries, in their relations. Where the frontals diverge by narrowness in front, behind the nasal processes of the premaxillaries, there the ethmoid is seen becoming fast bony from the substance of the perpendicular plate, and not by a separate upper bone, as in the *Struthionidæ*[1]. As to the facial bones, they yet retain much distinctness, and the prenasal and Meckelian rods still linger. The articular end of the latter rod is now ossifying fast, the two angular processes, so large in this type, are now bony. The fast coalescing roof and the coalesced floor are now of great thickness, and the diploe in this type is coarse (*op. cit.*, plate 86. fig. 14). In all these growing stages, tracing bone by bone, as it appears, we have not yet met with the presphenoid, nor seen the behaviour of the great ethmoidal wall in relation to the hinder skull. In the most advanced winter chickens these things are to be seen (fig. 18, *p.s.*, *p.e.*, *b.s.*)

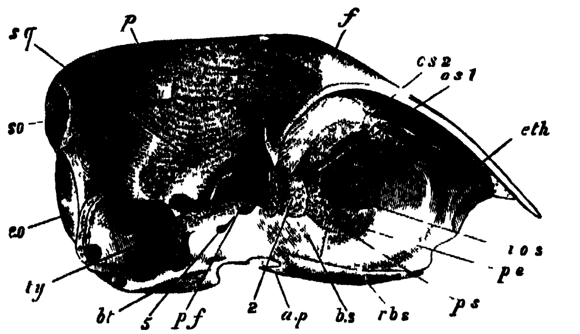

FIG. 18.—Skull of young *Fowl* of first winter, ninth stage, side view, × 1½ diameter. *o.s.* 1 and *o.s.* 2, the two small orbito-sphenoidal centres above the small presphenoid *p.s.*, which is only partially ossified at present. The sutures at this stage are very instructive. The fore-face has been removed, and the anterior edge of the perpendicular ethmoid (*p.e.*) is the posterior boundary of the cranio-facial cleft.

[1] *Phil. Trans.*, 1866, plate 8, fig. 10, *eth.*, *p.e.*

The presphenoidal region is merely that band of cartilage which lies partly above, but mainly behind, the fenestra (*i.o.f.*) A small ossicle has appeared in it close below the second orbito-sphenoid (*p.s.*, *o.s.* 2), the foremost orbito-sphenoid (*o.s.* 1) has coalesced with the perpendicular ethmoid.

From that bone the rostrum of the parasphenoid is still distinct (*r.b.s.*), but the perpendicular plate has now reached the basi-sphenoid (*p.e.*, *b.s.*), and between them, and below the still soft lower part of the presphenoid, there is a high vertical suture. This suture, and this steep bony wall *beneath* the presphenoid, are of the greatest interest to the morphologist. We saw that the basi-sphenoid was compound, having in it, besides the para-sphenoidal elements as investing parts, both the parachordal ends and the trabecular apices. So it is, for the Bird's skull runs over, or rather is built upon, the marvellously metamorphosed *first visceral arch*—the arch formed by the primordial "trabeculæ cranii." Counting from the spine, we have *three* cranial sclerotomes in the osseous stage. The *first* is formed on a notochordal and parachordal foundation; this is the "basi-occipital." The *next* is formed on a foundation partly parachordal and partly facial—the basi-sphenoid. The *third* is the "presphenoid," and it is tilted up over the forth-growing trabecular arch, the elements of which early coalesce at the mid-line, and the common crest of which is not, for a long time, in any way actually separate from the approximating roofs of the nasal sacs.

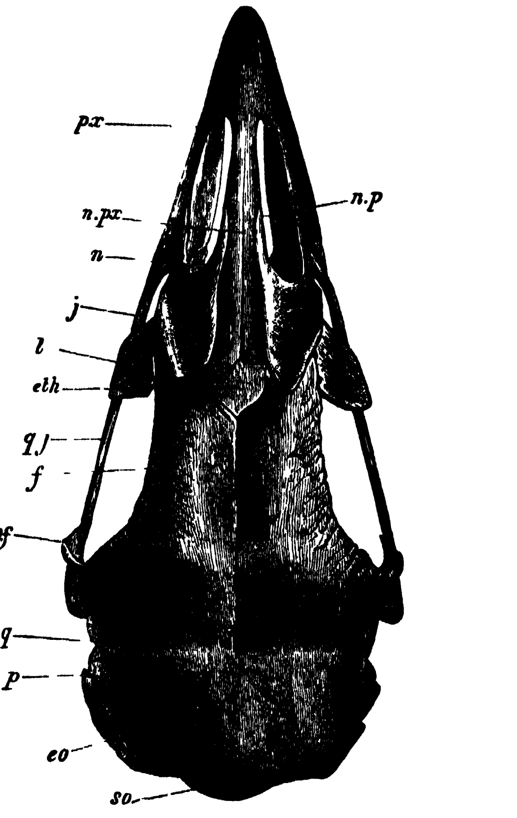

FIG. 19.—Skull of an old *Fowl*, tenth stage, × 1½ diameter, upper view. Above the line from *n.* is seen the large two-spurred nasal, the processes of which—upper and lower—are marked *n.p.*, the cartilaginous structures of the nose are not figured.

Cranium of Fowl—Tenth Stage.—In old birds we find an intense degree of ankylosis, and yet certain sutures are persistent to old age, or at least show some chink or mark of their original separateness. In this the Fowl agrees with most birds, but, being at no great height above the

Struthionidæ, it is not the strongest example of what a Bird's skull may be. In a bird's-eye view we see the separateness of the nasals, the nasal processes of the premaxillaries, the fore-end of the frontals, the top of the ethmoid, and the lachrymals (fig. 19, *n.px.*, *n.*, *f.*, *eth.*, *l.*) Below (fig. 20), the premaxillaries still have sutures with the palatines and maxillaries, and the latter has its jugal process, the jugal itself, and the quadrato-jugal, all distinct (*px.*, *pa.*, *mx.*, *j.*, *qj.*)

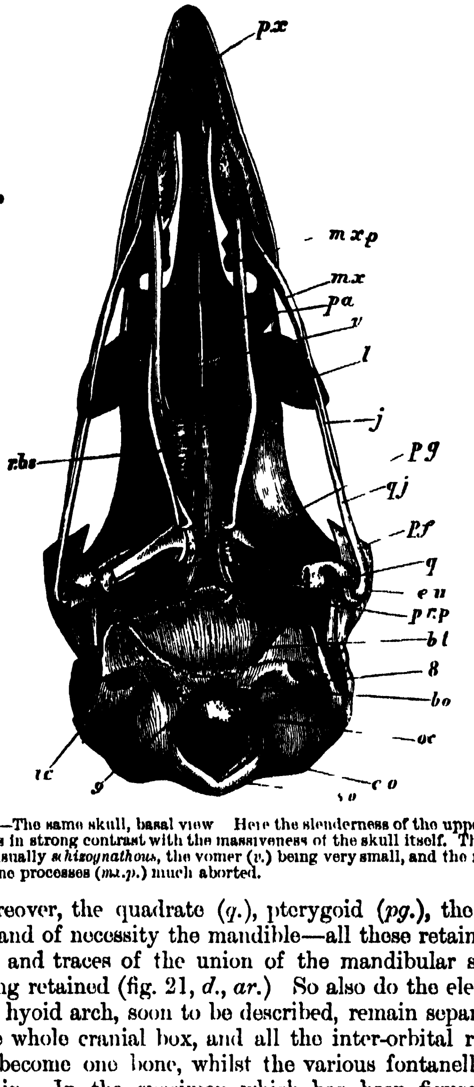

FIG. 20.—The same skull, basal view Here the slenderness of the upper facial rods is in strong contrast with the massiveness of the skull itself. This skull is unusually *schizognathous*, the vomer (*v.*) being very small, and the maxillo-palatine processes (*mx.p.*) much aborted.

Moreover, the quadrate (*q.*), pterygoid (*pg.*), the palatines, and of necessity the mandible—all these retain their joints, and traces of the union of the mandibular splints are long retained (fig. 21, *d.*, *ar.*) So also do the elements of the hyoid arch, soon to be described, remain separate.

The whole cranial box, and all the inter-orbital region, have become one bone, whilst the various fontanelles are filled in. In the specimen which has been figured the inter-orbital fenestra (*i o.f.*) is partly open, but it is often obliterated. Also we see that free periosteal bony growths have bridged over the temporal fossa, the post-frontal or "sphenotic" having met and coalesced with a zygomatic process of the squamosal (*p.f.*, *sq.*) In the lower view we still see the notochordal dimple on the transverse occipital condyle (*o c.*), and the hinder margin of the basi-temporal plate is still traceable in front of the passages for the vagus and the internal carotid burrows (*i.c.*) This thick bony mass is totally ankylosed to the basi-sphenoidal region above. The prootic and alisphenoidal regions are land-marked below by the foramen ovale (5), which is sometimes, as in Fishes, divided into two by a bony bar. So free is the bony growth that the basi-temporal has coalesced with the temporal wing of the exoccipital (*b.t.*, *e.o.*), and in front of this bridge we see a number of passages, burrows, galleries, windows, &c., leading above to the upper tympanic recess, in front to the anterior tympanic recess, below that to the eustachian opening, and on the middle of the inner face of the drum cavity a large hole which leads to the two fenestræ. The various bones of the palate are

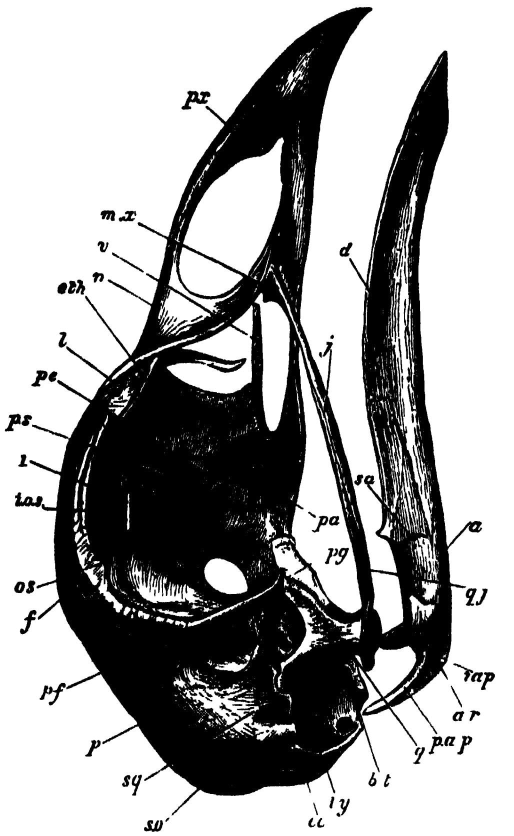

FIG. 21.—The same skull, side view, with the mandible a little dislocated. Here the temporal fossa is bridged over by the junction of the post-frontal and squamosal processes (*p.f.*, *sq.*) The processes of the mandible (*i.a.p.*, *p.a.p.*) are characteristic of this type, and of the *Anserinæ*.

scarcely in the least changed in form or *relative* size since the time of hatching (fig. 20), and the copious growths of cartilage belonging to the nasal labyrinth are always soft; these are not figured in the adult skull. There are, however, a few bony centres, the feeble representatives of the ossifications found amongst higher birds in this region. Thus, close in front of the broad wall-top of the ethmoid, in the substance of the septum nasi, there are two small ossicles, and on each side a similar bony point; the rest remained unossified, all save a small part of the attached margin of the pars plana.

The attenuated remains of the second post-oral, and the larger third post-oral arch, contain persistent cartilage. The elegant "columella auris" (fig. 22) is bony where it fits into the fenestra ovalis (*st.*), and the shaft, up to its rays (*m.st.*), also; but the short, notched supra-stapedial (*s.st.*), the tongue-shaped and fenestrate extra-stapedial (*e.st.*), and the slender, combined infra-stapedial and stylo-hyal (*i st.*), all these are still cartilaginous.[1] The rest of the second post-oral is reduced to the arrowhead-shaped lingual bone, the coalesced and partly ossified cerato-hyals (*c.h.*), and an elegant ridged phalangiform basi-hyal (*b.h.*) The free end of the combined glossal piece is soft. There is no tympanic in the Fowl; only in the Peafowl have we found one, and it is behind the membrane. The next arch, the thyro-hyal (first branchial in *Ichthyopsida*), is composed of two almost equal rods; the upper is only ossified in its

[1] Sometimes, even in the Fowl, the infra-stapedial has a spatulate stylo-hyal at its free end (see Professor Huxley's figure, *Proc. Zool. Soc.*, May 27, 1869, p. 399, fig. 5 B, *I. S.*)

distal third, and the lower is mainly bony; their basal piece is largely soft behind (fig. 15, *e.br.*, *c.br.*, *b.br.*)

The skull of the Fowl, and of the *Alectoromorphæ* generally, differs in certain respects from that of other *Schizognathæ*. In the *Gallinaceæ* as in the desmognathous *Rapaces*, the vomer is single; in Pigeons and Sand-Grouse it is absent; in all the others with open palates it is composed of two halves soldered more or less together. Some of the *Schizognathæ* possess an "os uncinatum"—as the Albatross and the Gull—a bone to be described hereafter; and others possess a pair of bones attached to the double vomer, namely, the "septo-maxillaries," known in Reptiles as the so-called "inferior turbinals." These bones, very small in all Birds, have been found by Mr Parker at the top and the bottom, as it were, of the schizognathous series; that is, in the Humming-bird (*Patagona gigas*), and in the Kagu (*Rhinochetus jubatus*). The latter is a Gruine bird, lying on the margin of the group towards the Night-Herons, whilst the Humming-birds are certainly amongst the most specialised type. All the *Schizognathæ*, except the Fowl tribe, have "meso-pterygoids." In certain *Schizognathæ* there is an "inferior labial" on the edge of the mandible, namely, in the *Rallidæ* (*e.g. Fulica atra* and *Gallinula chloropus*). These were found by the writer many years ago. Upper labials have not as yet turned up in these types, although they have been figured carefully in the Rhea (*Phil. Trans.*, 1866, plate 10, fig. 14, on each side of *r.b.s.*, close under the inferior turbinal *i.t.*), and the Rhea is a much lower type than the birds under notice. As in the *Gallinaceæ*, the *Schizognathæ* generally have little development of the tympanic ring, but in *Ægialitis hiaticula* there is one large and three or four lesser bones on each side; they occur in *Numenius arquata*.

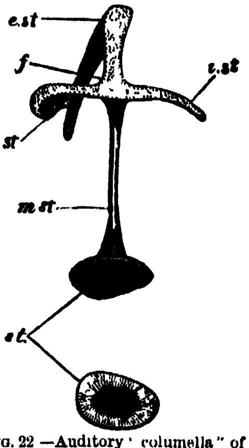

FIG. 22.—Auditory "columella" of *Chicken*, ninth stage, × 6 diameters; lateral and basal views. *st.* stapes; *m.st.*, medio stapedial bar; *s.st.*, super-stapedial; *e.st.*, extra-stapedial; *i.st.*, infra-stapedial; the end of this latter process is the stylo-hyal, often more dilated than in this specimen; *f.*, fenestra in extra-stapedial plate.

A full and adequate idea of the degree of the metamorphosis of a Vertebrate skull attained to in Birds can only be obtained by observation of what is to be seen in that of the higher arboreal types. But some of the *Carinatæ* are half Struthious, and they possess that low kind of skull which is called "Dromæognathous," best seen in *Dromæus*, the Emeu.[1] This kind of skull once understood, the relation of that of the Fowl to that of types far above and far below it will be clearly seen; for we must describe the Desmognathous, Ægithognathous, and Saurognathous varieties also.

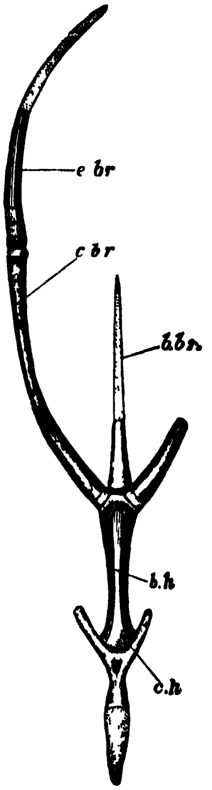

FIG. 23.—"Os hyoides of adult *Fowl*, tenth stage, × 1½ diameters. *c.h.*, ceratohyals (confluent); *b.h.*, the so-called basi-hyal, answering to the first basi-branchial of a Fish; *b.br.*, basi branchial, or uro-hyal, answering to the rest of the basi-branchial series of a Fish; *c.br.*, *e.br.*, together form the thyro-hyal, answering to the first cerato- and epi-branchials of a Fish.

[1] *Phil. Trans.*, 1866, plates 11-13.

The DROMÆOGNATHOUS *Type—Cranium of* Tinamus variegatus.—Professor Huxley (*Clas. of Birds*, p. 425) says, "The *Dromæognathous* birds are represented by the single genus *Tinamus*, which (as Mr Parker has shown)[2] has a completely struthious palate. In fact, the vomer is very broad, and in front unites with the maxillo-palatine plates, as in *Dromæus*, while behind it receives the posterior extremities of the palatines and anterior ends of the pterygoid bones, which thus are prevented, as in the *Ratitæ*, from entering into any extensive articulation with the basisphenoidal rostrum. The basi-pterygoid processes spring from the body of the sphenoid [they are not segmented plates of cartilage attached to the parasphenoid, as in the true *Carinatæ* (see above)], not from the rostrum, and they articulate with the pterygoid very near the distal or outer ends of the latter bones." In the Fowl, as we have just seen, the fore-end, or main part of the pterygoid, glides on the rostral plate. "The head of the quadrate bone is single, as in the Struthious Birds (Parker, *l.c.*)" To this we may add that the basi-temporals are very feebly developed, as we find from examination of three adult species—*T. robustus*, *T. variegatus*, and *T. brasiliensis* sive *major*.[3]

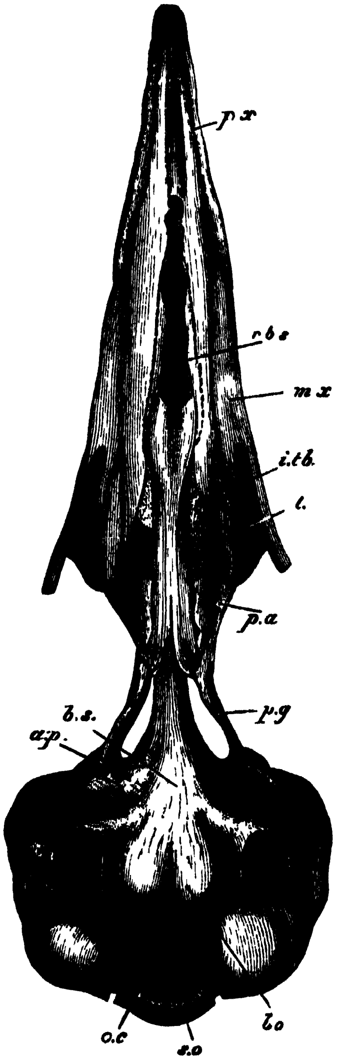

FIG. 24.—Skull of *Tinamus variegatus*, adult, palatal view, × 2 diameters. The greater part of the jugal bars and the quadrate bones have been removed. *r.b.s.*, fore-end of parasphenoidal rostrum; *a.p.*, anterior pterygoid process (basi-pterygoid).

If Professor Huxley's description be compared with the accompanying figure (24) of the Tinamine skull this variety will be easily understood; the lettering is the same as in the figures of the Fowl's skull. For further details the reader is referred to Mr Parker's *Memoirs* above referred to, especially that on the Struthious types (*Phil. Trans.* 1866, plates 7-15).

The DESMOGNATHOUS *Type of Skull.*—This kind of skull occurs in such a variety of families that, notwithstanding its importance to the morphologist, it is not of so great a value to the zoologist. Nor indeed is it quite equal to some of the groups in value, being due to a

[2] A note is given below as follows:—"On the Osteology of Gallinaceous Birds and *Tinamous* (*Transactions of the Zoological Society*, vol. v. 1864). Sundevall, however, had already said of *Tinamus*, *Rhynchotus*, and *Crypturus*, 'Struthiones parvos referunt.'" The last two are merely sub-genera of *Tinamus*.

[3] The writer hopes to show the development of this type of skull at some future time; an embryo of *Rhynchotus rufescens* is treasured up for this purpose.

condition arising rather from an excess of osseous deposits than from any very striking metamorphosis of primordial elements. The skull of the *Schizognathæ* easily runs, as it were, into this type; whilst it crops up among such simple palates as those of the Fowl tribe, namely, in *Crax globicera;* and *Talegalla Lathami* in old age is nearly desmognathous. So also on the Ardeine borders of the *Gruidæ*, the Kagu (*Rhinochetus jubatus*),[1] is almost a Night-Heron, and nearly desmognathous. In another region *Nyctibius* almost comes across to the gigantic Goatsuckers (*Podargus*) and the Oil-Bird (*Steatornis*). (See Huxley, *Clas. of Birds*, p. 456.) In the paper just referred to (p. 453) the *Desmognathæ* are thus described :—"Those Cuvierian *Grallæ* and *Natatores* which are not schizognathous, the *Accipitres* or *Raptores*, the *Scansores* [excluding the *Picidæ*], and among the *Passeres*, most of the *Fissirostres*, all the *Syndactyli*, and *Upupa*, may be termed desmognathous. In these birds the vomer is often abortive, or so small that it disappears from the skeleton. When it exists it is always slender, and tapers to a point anteriorly. The maxillo-palatines are united across the middle line, either directly or by intermediation of ossifications in the nasal septum. The posterior ends of the palatines and anterior ends of the pterygoids articulate directly with the rostrum, as in the preceding division" [the *Schizognathæ*].

It is possible to make several important divisions in the kind and degree of desmognathism, as follows, namely—

a. Direct.—In Falcons and Geese, the maxillo-palatines meet below at the mid-line, as in the Mammal. Two sub-varieties of this form occur, as in the Falcon, where the nasal septum is ankylosed to this hard palate, and in the Goose, where it remains free.

b. Indirect.—This is very common, and is best seen in Eagles, Vultures, and Owls. The maxillo-palatines are ankylosed to the nasal septum, but are separated from each other by a chink.

c. Imperfectly direct.—This is where the maxillo-palatine plates are united by harmony-suture and not by coalescence. Example—*Dicholophus cristatus.* In young Falcons and Hawks the palate is at first indirect, is then imperfectly direct, and at last perfectly direct.

d. Imperfectly indirect.—Here the maxillo-palatines are closely articulated with, and separated by, the "median septo-maxillary," but there is no ankylosis. Example—*Megalæma asiatica.*

e. Double Desmognathism.—This is seen in *Podargus*, where the palatines as well as the maxillaries largely coalesce below; to a less extent this is seen also in the larger Hornbills (*Buceros*). (Huxley, *op. cit.*, pp. 445, 446, figs. 27, 28.)

f. Lastly, a compound form, in which the ægithognathous skull becomes desmognathous, is seen in certain *Coracomorphæ* (*Gymnorhina*, &c.), as will be shown below.

Professor Huxley's remark, that the vomer, "when it exists, is always slender, and tapers to a point anteriorly" (p. 435), is modified by a note he gives on the same page with regard to the broad emarginate vomer of *Falco.* It has a similar, but not equal, enlargement in front in the Sacred Ibis (*Threskiornis æthiopicus*), and the knife-shaped vomer of the Duck tribe is often thick at the infero-anterior angle, as may be seen in *Œdemia nigra*, *Querquedula caudacuta*, and *Mareca penelope*, but the vomer of the *Chenomorphæ* is compound, and the antero-superior bone, whose lower angle in part is enlarged, is the median septo-maxillary; this may be seen in young Geese, and in the adult Crested Screamer (*Chauna chavaria*).

Here it will be necessary, in order to show the value of these types of skull, to insert Professor Huxley's masterly handling of the modifications of the *desmognathous* skull, and the groups in which it is present. It is open to us, however, to modify some statements of his and to superadd others, for the observation of which the present writer has had much greater leisure, and the advantage of having dwelt long on the subject.

At page 460 (*op. cit.*) we read: "Not fewer than seven groups of families appear to me to be clearly distinguishable in this subdivision, viz., the *Chenomorphæ*, the *Amphimorphæ*, the *Pelargomorphæ*, the *Dysporomorphæ*, the *Aetomorphæ*, the *Psittacomorphæ*, and the *Coccygomorphæ*."

1. The *Chenomorphæ.*—"The lachrymal region is remarkably long [save in the Screamer (*Chauna*)]. The basi-sphenoidal rostrum has oval, sessile, basi-pterygoid facets, like those of the *Alectoromorphæ.* The flat and lamellar maxillo-palatines unite and form a bridge across the palate." Yet each of these plates has a large obliquely-ascending process; the vomer lies on the groove formed by the union of the maxillo-palatines; the more or less ossified septum, in old age, coalesces, by its outstanding processes, with those plates. The internal, but especially also the posterior angle of the mandible is largely developed, and so also is the transpalatine angle of the palatine. The glosso-hyal is very large and spatulate, and the thyro-hyals are flat and broad where the two unite. A remarkable structure is found in Ducks and Swans, namely, an ossicle on each side between the palatines, and stretching towards the maxillo-palatine plate: these bones are the "interpalatines;" they tend to carry on the hard palate.

2. The *Amphimorphæ.*—"The genus *Phœnicopterus* is so completely intermediate between the Anserine birds on the one side and the Storks and Herons on the other, that it can be ranged with neither of these groups, but must stand as the type of a division by itself. Thus the skull has the long lachrymo-nasal region, the basi-pterygoid facets [not so; see *op. cit.*, p. 437, where they are truly said to be rudimentary—they are the merest prickles], the prolonged and recurved angles of the mandibles, the laminated horny-sheath of the *Chenomorphæ;* but the maxillo-palatines are spongy [scarcely more so than in the Swan *et hoc genus omne* of the Anserines and Anatines], and the general structure of the rostrum is quite similar to that found in the Storks and Herons." The nasals are thoroughly Anserine, having their crura separated by a rounded notch; their palatines are quite Anserine, but are broader behind, being exactly like those of the Screamer; and yet they cut off the meso-pterygoid, which coalesces with the palatine. This the Storks and their allies do; the *Chenomorphæ* do not. The pterygoids are like those of *Threskiornis* and *Platalea*, but the vomer is intermediate between that of the Goose and the Spoonbill. The orbital processes of the palatines, or "ethmo-palatines," run together as arched laminæ from the body of the bone to the maxillo-palatine floor. They are very shell-like at first, and are attenuated in front. They coalesce together, and send down a bony keel of exquisite thinness in their hinder part. There is a part separate from the rest in front, just where they begin to narrow; this is obviously the median septo-maxillary. Behind, where the palatines shoot below the rostrum of the sphenoid, each bone sends down a lamella; each of these is bound to its fellow by fibrous tissue, and between these the vomer is wedged; the thin plate belongs mutually to the palatines and the azygous vomer. In all the ordinary *Chenomorphæ* the ethmo-palatine spurs are long: in *Phœnicopterus* enormously so; in the Screamer they are very short. Hence the palato-vomerine structures of the *Amphimorphæ* are Anserine, but much modified. So also in the hyoid apparatus; and the huge glosso-hyal is, although cartilaginous, the true counterpart of that of a Swan.

[1] See *Trans. Zool. Soc.*, vol. vi. plates 91 and 92.

3. The *Pelargomorphæ.*—"There are no basi-pterygoid processes, and the palatines usually unite for a greater or less distance behind the posterior nares; but they send down no vertical plate from their junction." In the *Ardeidæ* they do not unite; in all these forms the coalesced part is short as compared with that of the Cormorants and Pelicans; in both *Scopus* and *Balæniceps* the ankylosed part is carinate below (*Trans. Zool. Soc.*, vol. iv. plate 65, fig. 1, *pal.*) 'The maxillo-palatines are large and spongy. The angle of the mandible is truncated," except in *Platalea* and *Ibis*. The vomer is smallish and cultrate in *Ciconia nigra;* larger by far, cultrate, and pedate at the end in *Thresciornis æthiopicus;* as large in *Platalea leucorodia*, but pointed in front and carinate below. Even in the last of these forms, in a half-grown individual, no sign of a median suture was seen. The vomer of *Scopus* is sharply cultrate above and rounded below; it reaches beyond the maxillo-palatine mass. In *Balæniceps* (*op. cit.*, p. 308, plate 65, fig. 1, *v.*) the vomer is like that of *Scopus* and *Ciconia*, but it is actually smaller than either. In most of these Ciconian and Ibidine types[1] the vomer is evidently azygous, but in all the skulls of *Ardeidæ* now before the writer, viz., one or two species of each of the following genera, *Ardea*, *Botaurus*, *Nycticorax*, *Garzetta*, *Tigrisoma*, the vomer is double, large, and charadrian.

In *Ardea cinerea* the vomer is coalesced behind with the long, elegant, bicarinate palatines, and in front runs its point in between the free retral lobes of the maxillo-palatines. The moieties have each a rounded keel, and those keels run parallel at first and then run into each other in front; above, the two halves form a deep fossa, in which the sub-carinate parasphenoid glides. The edges of this trough are roughly tuberculated and turned over, like the rim of a cup; the primary suture between the halves is retained behind for half the length of the bone. In several *Ardeidæ* an additional maxillary bone—the "post-maxillary"—is formed behind the angle of the maxillary. It is small in *Ardea garzetta* and *Botaurus stellaris*, and of good size in *Botaurus viridis* and *Nycticorax ardeola*. This bone was first found by Mr Parker in the Emeu. In *Tigrisoma leucolophum* there is a pair of "inter-palatines," as in the Duck tribe. In the *Pelargomorphæ* the charadrian type reaches its culmination; yet the most exquisite forms, such as the Egrets and smaller Bitterns, and the most gigantic, as the Adjutant, are evidently specializations of a type similar to the pluvialine *Schizognathæ*.

4. The *Dysporomorphæ.*[2]—"The rostrum is long and pointed, and more or less curved; and the external nasal apertures are very small. There are no basi-pterygoid processes. The palate bones unite for a considerable distance behind the posterior nares, and send down a vertical crest at their junction. The maxillo-palatines are large and spongy. The angle of the mandible is truncated."

The inferior crest of the combined palatines is largest in *Pelecanus*; above, in *Phalacrocorax* and *Sula*, this plate is grooved for the sphenoidal rostrum, but in the Pelican there arises a huge crest, and the rostrum of the sphenoid rises rapidly out of its way. Here the *secondary* palatine arch has the same *habit* as the primary trabecular arch—a modification constant in birds in the latter. All the parts in front of the very mobile cranio-facial hinge are molten together into one mass, and the nasal labyrinth is in its most aborted state.

In *Phalacrocorax* the perpendicular ethmoid is of small antero-posterior extent. There is no presphenoid, but merely a small V-shaped orbito-sphenoidal band of bone above the optic passage. The same structure is seen in *Himantopus* and *Eurypyga*. In the Cormorant an oblong ossicle lies on the commencement of the zygoma. It is large in *P. carbo*, and small in *P. graculus*. A still larger ossicle has heightened the zygoma in *Sula alba*. This is the "post-maxillary." In *Sula alba* the basi-temporals are as little developed as in the *Dromæidæ*, less than in any other Carinate bird. Behind each moiety there is a large oval opening, not far in front of the occipital condyle; this exposes the loose diploë within. The small eustachian tubes open at a little distance from each other, in a wide shallow fossa, on the part where the three elements of the parasphenoid meet. In both the Pelican and the Cormorant there is an elegant, crescentic, lipped, free margin to the very Ardeine basi-temporal plate. In *Sula alba* the columella auris is very long and bent. It has a small cartilaginous extra-supra-stapedial process, and a long attenuated cartilaginous infra-stapedial, terminated by a bony fusiform stylo-hyal. The hinge for the mandible is very far back in *Sula*, whose cranio-facial hinge almost rivals that of the Parrot and Toucan. In the Cormorant the mandibular articulation is almost carried as far back as in the Crocodile. In *Sula alba* the zygoma is very thick in front, and is suddenly reduced to an extremely thin bar, where it passes into the upper beak.

5. The *Aetomorphæ.*—"The rostrum is more or less arched and hooked at the tip. Basi-pterygoid processes may be present or absent. The maxillo-palatine processes may be concavo-convex lamellæ, or may be spongy and fill up the base of the rostrum; but they are always [except in *Dicholophus*, a genus which the writer adds to the group] united with an ossification of the septum. The breadth of the articular surface at the distal end of the quadrate bone is greater than its length, the outer condyle extending about as far downwards as the inner." This is best seen in the Cariama (*Dicholophus*), and in the Owls, Hawks, and Falcons; in the larger Old World Vultures (*e.g.*, *Gyps fulvus*) it is not so well seen. The angle of the mandible is never recurved." At pp. 441 and 442 *op. cit.* it is stated that "the maxillo-palatines unite with one another and with the extremity of an ossified septum, so as to fill up the maxillo-palatine valley." In the carefully prepared specimens before the writer, it is found that there is a space between the right and left maxillo-palatine, not only in the *Cathartidæ*, where it is evident, but also in *Gypogeranus*, where it is least. Intermediate between these types come the Old World Vultures and the Eagles. The skulls at hand give the following results, viz.:—

a. Perfect indirect Desmognathism.
Sarcorhamphus papa, *Aquila* (sp. pl. including *Helotarsus ecaudatus*), *Gyps fulvus*, *Neophron percnopterus*, *Asio otus*, *Asio accipitrinus*, *Aluco flammeus*, *Ketupa ceylonica*, *Athene noctua*, *Strix stridula*, *Elanus cæruleus*.

b. Imperfect direct Desmognathism.
Dicholophus cristatus.

c. Perfect direct Desmognathism.
Falco peregrinus, *Falco tinnunculus*, *Falco æsalon*, *Accipiter nisus*, *Buteo vulgaris*, *Circus cyaneus*, *Haliastur indus*.

With regard to the basi-pterygoid processes, they are most aborted in *Dicholophus*, *Helotarsus*, and *Gyps*. They reappear as aborted prickles or knobs in some Eagles, in *Neophron*, *Elanus*, *Circus*, and *Accipiter*, and in the young of these they are rather large. In *Haliastur indus* they are large, rounded flaps, with no cartilage on their end. Then come *Gypogeranus*, the *Cathartidæ*, and the Owls, in which they are constant. In all the Owls, as in Pigeons and some of the *Turnicidæ* (see *Trans. Zool. Soc.*, vol. v. plate 34, fig. 2, *m.o.f.*), the slow growth of the occipital region of the chondro-cranium leaves a membranous space over the foramen magnum. This is not, or is very rarely

[1] *Balæniceps* has the head of a Stork, but its body is largely Ardeine.

[2] *Dysporus*, a generic name applied to the Gannets by Illiger.

filled up by even the bony growths; it remains as the "median occipital fontanelle."

The vomer in this group is of great interest, being extremely variable, and often having a supplementary bone attached. It is azygous. The palatines also, which have rounded posterior angles and double keels, often have a medio-palatine where they unite, and also receive the meso-pterygoid spur. In some types, as *Gyps fulvus*, the large rounded palatine flap is partly severed off as a "transpalatine." Where the ascending laminæ of the palatines meet below the sphenoidal rostrum, there a bony deposit takes place; this, if truly azygous, is a medio-palatine; if oblique, it is one of the meso-pterygoids, which, in the *Rapaces*, get between the palatines, coalesce with each other, and form a keystone, as in *Ulula stridula*. In others, as the young of *Falco tinnunculus* and the adult *Helotarsus ecaudatus*, there is one small, obliquely-placed ossicle in the front of the palatine suture. In *Neophron percnopterus* there is one free meso-pterygoid attached to the right hinder fork of the vomer. In *Dicholophus cristatus* there is a large medio-palatine wedged in in front, and to it the cultrate, fenestrate, and pedate vomer is attached. In the Falcons the vomer is pedate, and, in the larger kinds, fenestrate. In *Ulula stridula* there is a small vomer attached to a small medio-palatine, and having over it an equally small median septo-maxillary. The latter bone is large in *Asio otus*, and small in *Neophron percnopterus*, *Circus cyaneus*, and *Haliastur indus*. The vomer is most aborted in the Eagles and Vultures (often absent); but it is long in *Neophron*. We have found a small bony wedge (oblique meso pterygoid) in *Sarcorhamphus papa*. Professor Huxley's figure of the skull of *Gypogeranus* is deficient in not showing a small vomer (fig. 24, p. 442). A specimen sent to him by the writer (after the paper appeared) has this little bone distinct. The frowning brow is obtained in these birds by a huge super-orbital process of the lachrymal in *Dicholophus*, *Gyps*, and *Falco*. In many kinds (Hawks, &c.) there is a distinct super-orbital at its extremity. The eyeball, with its massive bony rim, is quite equal in *Dicholophus* to that of the diurnal *Rapaces* generally. Its hyoid also is thoroughly Raptorial. Its glossal (double) piece is spatulate, and, like that of its congeners, approaches the glosso-hyal of the Parrots in breadth. Unlike its congeners, the Cariama has its nasal septum but little ossified; and it possesses an "os uncinatum," propping up the pars plana, as in the Gull, Albatross, and many other birds.

A description of the palate of the Sparrow-Hawk (*Accipiter nisus*, will illustrate that of Raptorial birds generally, and also the meaning of the term *desmognathous*.[1] The specimen figured (fig. 25) was a half-developed nestling. Its round occipital condyle, and the various foramina (8, 9), are shown in the occipital region, and outside and above this arch are seen the hinder face of the opisthotic (*op.*), and in front of the tympanic ala of the exoccipital (*e.o.*) there is an uncinate bone in relation with the prootic, opisthotic, squamosal, and exoccipital, where they all meet together. This is the "pterotic" (*pto.*), a huge bone in Osseous Fishes, and walling-in much of the labyrinth. In Serpents only a film of ectosteal bone represents it, and in Lizards such a plate appears, overlapping cartilage which has begun to calcify. It develops and becomes part of the parotic process. The basi-temporal plate (*b.t.*), the rostrum, with its arrested basi-pterygoids (*b.pg.*), are shown, and on each side the double condyle of the quadrate (*q.*), characteristically placed tranversely. The zygoma is composed of thin needles of bone (*qj.*, *j.*); the zygomatic process of the maxillary is, behind, bound up with the jugal and quadrato-jugal, and in front passes into the upper dentary region, half overlapped by the

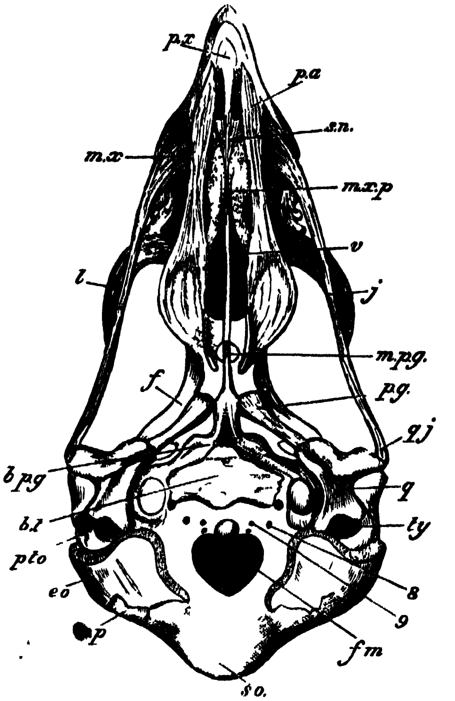

FIG. 25.—Skull of nestling *Sparrow-Hawk* (*Accipiter nisus*), palatal view, × 2 diameters. The circular space on each side of the basi-temporal (*b.t.*) is the opening of the anterior tympanic recess The meso pterygoids (*m.pg.*) show part of their lower face on the post-palatine region; the basi-pterygoids (*b pg.*) are mere knobs, and the common eustachian opening is seen between them. The maxillo-palatine plates (*mx p*) are dotted to show their spongy character.

dentary process of the premaxillary (*px.*) The dentary edge of the maxillary sends inwards the maxillo-palatine plate (*mx.p.*), which meets its fellow at the mid-line, and also grows retrally and superiorly into an elegant shell-like mass.

The right and left plates lie edge to edge, as in the adult Cariama, and are imperfectly direct in their desmognathism. The palatine processes of the premaxillaries bind the fore-ends of the palatines, which in turn bind under the maxillo-palatine plates. The gap in front is filled with the fast ossifying septum nasi; it is pedate in front, and behind sends out a process on each side; these spurs ankylose afterwards with the maxillo-palatine plates, and they with each other. The palatine bones (*pa.*), strap-like, widen backwards, and then gently narrow to the end, leaving no sharp postero-external angle. The wedge of bone which has been fretted off from the fore-end of each of the rod-like pterygoids (*pg.*) binds on the postero-superior edge of each palatine, and the inner plate of these bones covering the under surface of the sphenoidal rostrum imperfectly, allows part of these bony wedges—the "meso-pterygoids" (*m. pg.*)—to be seen from below. The bird has all the *periotic* bony centres, viz., *five*, as in Osseous Fishes; it has distinct cartilaginous orbital alæ, which are, like the presphenoid, separately ossified, besides an azygous ossification in membrane belonging to the same category.

6. The *Psittacomorphæ*.—The uniformity of this group of *Desmognathæ* is as remarkable as the variability of the last, and yet it is potent in genera and species. "The rostrum (see *op. cit.*, p. 465) is arched and hooked at the extremity, and is regularly articulated with the frontal region of the skull." Therefore we find that the cranio-facial cleft is complete—a state of things not often occurring. The development of this type has not been observed, yet we can interpret the metamorphic results by other

[1] See *Monthly Microscopical Journal*, Feb. 7, 1873, p. 45, plate 5, fig 2. A paper by the same writer in the *Linnean Transactions*, 1875, may be consulted for copious illustrations of the *Desmognathæ*.

types. "Basi-pterygoid processes [and vomers] are wanting. The palatines are vertically elongated posteriorly, while anteriorly they are horizontally flattened, and movably united with the rostrum. The maxillo-palatines are spongy. The lachrymal and post-orbital bend towards one another, and frequently unite below the orbit." This is by the intervention of a large "os uncinatum," which is best seen in small types, such as *Psephotis multicolor*, and *Agapornis pullaria*, where this part does not unite with the post-frontal. In *Microglossa*, *Calyptorhynchus*, *Plyctolophus*, *Melopsittacus*, &c., the temporal fossa is also bridged over by junction of the zygomatic process of the squamosal with the os uncinatum. "The orbital process of the quadrate bone is very small, and its distal presents only one facet (which is compressed from side to side, and convex from before backwards) for the mandible. The rami of the latter are deep, and pass into one another by a rounded symphysis." The glosso-hyal is spatulate, and the basi-hyal is alate behind. In the fore-face are some things worth noting. The septum nasi is a thick wall of bone; the alæ nasi are soft in *Psephotis multicolor*, they have an annual ossicle found in them in *Melopsittacus undulatus*; whilst in *Palæornis torquata* this part is largely ossified and ankylosed to the upper jaw, and the alinasal turbinal is partly calcified. In one small kind we saw the trace of a small medio-palatine. The pars plana is narrow and ossified, and is ankylosed to the lachrymal; the inferior turbinal is soft.

7. The *Coccygomorphæ*.—This is another polymorphic group, and is not in any sense, either zoologically or morphologically, the equivalent of the last. Yet it is almost impossible to separate the families by any character of importance. If the *Podargus* must be linked with the Kingfisher, the Goatsucker and its allies cannot be removed, notwithstanding their *schizognathous* palate. Here, however, we are dealing with the desmognathous forms. Professor Huxley makes four sub-groups, and then remarks (p. 467): "It appears to me not improbable that it may hereafter be desirable to divide this group into four." The characters of the skull are thus given (p. 466): "The rostrum presents very various forms, and may be movably articulated with the skull. Basi-pterygoid processes are present in only one genus (*Trogon*)."[1]

The Oil-bird (*Steatornis caripensis*) has very large basi-pterygoids, thus connecting the Goatsuckers with *Podargus*. "The maxillo-palatines are usually more or less spongy. The palatines are not developed into vertical plates, but are, as usual, horizontally flattened. The distal end of the quadrate has the ordinary form." The vomer is small in Hornbills, Toucans, and *Scythrops*; but they have a second bone in front of the azygous vomer, viz., the "median septo-maxillary," as in the Goose tribe and others. In *Podargus*, when the lower palatine floor—like that of a Mammal—is cut away, there are to be seen three small ossicles; the first of these is the vomer, the others are medio-palatines. In *Megalæma* the vomer is very large and forked in front. In the Kingfishers and Hoopoes there is no vomer; there is a trace in *Corythaix*. The palatines may be rounded behind as in *Cuculus* and *Buceros*, have a retral spur to the transpalatine part as in *Rhamphastos Alcedo*, and *Upupa*, or be very broad, with a large *passerine* transpalatine angle, as in *Podargus*.[2]

The ÆGITHOGNATHOUS *Type—Cranium of the Rook.*—This figure and its description must do duty for the whole of the *Ægithognathæ*, which, with a little cutting and contriving, may be made to cover the *Coracomorphæ* entirely, with enough at its corners also to be superimposed upon the Swifts and the Hemipods, and that remarkable charadrian bird, *Thinocorus*.[3] It is worth while to remember that these types are actually the highest, the most metamorphosed, and the most specialized; not so high in some respects as the Mammal, yet no Mammal comes near them in adaptive modification, not even the one which has the taste to admire, and the wit to describe them. We learn from no less an authority than Mr G. R. Gray that of the 10,000 known birds half belong to this group; the Old World types of which, more especially, are such accomplished creatures. The *Nectarinia* is the smallest, and the Raven the largest of this huge, but morphologically very uniform, group.

The skull of a fledgling Rook (fig. 26) illustrates the highest bird of this type; the occipital condyle (*o.c.*) is hemispherical, the basi-temporal plate (*b.t.*) is an almost transverse band of bone, the rostrum of the parasphenoid (*pa.s.*) is without any developed basi pterygoids, the cranio-facial hinge is nearly perfect, but the nasals and nasal processes of the premaxillaries are thin splints set into the frontals; they do not form a perfect hinge.

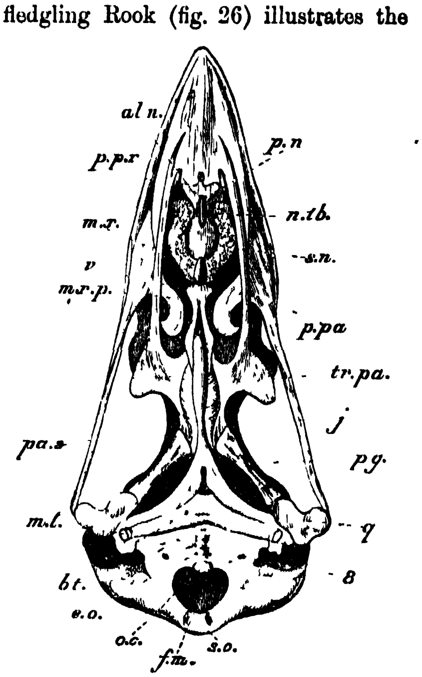

FIG. 26.—Skull of nestling Rook (*Corvus frugilegus*), palatal view, natural size. The prenasal region (*p.n.*) is trifoliate; the medium rod, looking forwards, is the remains of the prenasal or basi-trabecular bar; the lateral leaves of cartilage looking backwards, are the recurrent ventral extremities of the trabecular cornua; between the alinasal turbinals the base of the septum nasi retains its flatness; it is formed by the inter-nasal part of the trabeculæ.

The palatines are developed into cartilage at their hinder angle; this is a large flap, and, ossifying late and separately, has time to become chondrified first (*t.pa.*); the pterygoids (*pg.*) are phalangiform, and lose their meso-pterygoid spur, which soon coalesces with the palatines. The maxillo-palatine processes are hooked and flattened, and often enlarged at their inner extremity, so as to become pneumatic.

But the distinguishing character of the type is *the union*

[1] For a figure of this skull, see Professor Reinhardt's paper on the "Os uncinatum" ("Om en hidtil ukjendt Knogle i Hovedshallen hos Turakoerne *Musophagidæ*, Sundev," *Særtryk af "Videnskabelige Meddelelser fra den Naturhistoriske Forening i Kjøbenhavn*," 1871). In this paper figures are given of the skull of *Corythaix*, *Musophaga*, *Schizorhis*, and *Trogon*.

[2] See Professor Huxley's figures, those of M. Reinhardt just referred to, and Dr Murie's valuable papers "On the Skeleton of Todus," *Proc. Zool. Soc.*, May 21, 1872, plate 55, pp. 663–680; "On the Genus *Colius*," *The Ibis*, July 1872, plate 10, pp. 261–280; "On the Motmots," *Ibis*, Oct. 1872, plates 13–15, pp. 383 412; "On the Upupidæ," *Ibis*, April 1873, plates 5–7, pp. 181–211.

[3] For descriptions of the skulls of Passerine birds, see Parker on the "Skull of the Crow," *Monthly Micr. Jour.*, Nov. 1, 1872; on that of the "Tit" (*Parus*), *ibid.*, Jan. 1, 1873; and on that of the "Thrush," *ibid.*, Mar. 1, 1873. See also, as referred to by Professor Huxley, Nitzsch's article "Passerinæ" in Ersch and Gruber's *Encyclopædie*, 1840, and his paper, "Ueber die Familie der Passerinen," in the *Zeitschrift für die Gesammten Naturwissenschaften*, 1862. As the figure given above is of a young bird, the reader is also referred to Professor Huxley's "Palatal View of the Raven's Skull" (*op. cit.*, p. 451, fig. 32); of that of the "Grosbeak," fig. 33; and of the "Swift," fig. 34. See also Murie "On Fregilupus." *Proc. Zool. Soc.*, June 16, 1874, plates 61, 62.

of the vomers with the alinasal wall and turbinal, and the possession, by the embryo bird at least, of a pair of "upper labials," corresponding to the *inner* upper pair in Snakes, Sharks, and Skate; the vomers are either partial or entire ossification of these cartilages. Besides these, there reappear in most of the *Ægithognathæ* the so-called "inferior turbinals," or nostril-bones of the Snake and Lizard, and these are attached to the shoulders of the double, and generally, ox-face-shaped vomer.[1] The nasal labyrinth is very large in the Rook, but does not differ in essentials from that of the Fowl, above described.

The septum nasi (*s.n.*) retains much of its original flatness below, and is thus *alate*; the vomer (*v.*) of the young bird is broad and grooved above; in the old bird, ossification running some distance along the alinasal wall and alinasal turbinal (*a.tb.*), the bone becomes not only emarginate, but also very massive in front. In the Lark (*Alauda arvensis*) this bony matter in the macerated skull leaves huge goat-horn processes to the fore-angles of the vomer. Ægithognathism occurs in different degrees; thus, we may have its morphological conditions—

a. Incomplete: as in *Turnix*.
b. Complete var. 1: *Pachyrhamphus, Pipra.*
c. Complete var. 2: *Corvus, Alauda.*
d. Compound: *Gymnorhina, Artamus.*

a. Incomplete. Here the large "labials" are imperfectly ossified by the two vomers, and these bones are only strongly attached to the nasal labyrinth by fibrous tissue.

b. Complete var. 1. In these cases the labials are often only imperfectly ossified by the vomerine centres; these centres also are distinct from those ossifying the alinasal cartilages; but the union of these parts is perfect.

c. Complete var. 2. In these cases the labials are often small and completely ossified by the vomers; but the bony deposit runs riot into the alinasal wall and turbinal, so that in the adult all distinction of the parts may be lost.

d. Compound. Here the flat arcuate end of the maxillopalatine is free, but the mass of that plate meets its fellow of the opposite side and coalesces with it, and with a highly ossified nasal septum. In these *Southern types* the "transpalatine" is a long spike, as in the *Alcedidæ*. In all these varieties the septo maxillaries may, and do mostly, occur. They cannot always be found.[2]

Concluding our remarks upon this morphological type, its value is shown by this—that it is exactly superimposable upon the *Coracomorphæ*, if we reject the bird that shows its initial or imperfect condition, as the Hemipod, and stubbornly hold to the popular view that Swifts are a kind of Swallow for as to their nobler part, their head, they are merely a variety of that type. Thus the zoologist and the morphologist may here join hands.

The SAUROGNATHOUS *Type - Cranium of the* Picus Minor.—This group, Professor Huxley's *Celeomorphæ* (*op. cit.* 448 and 467), is so remarkable and difficult of determination, that although our author saw clearly many most important characters (quite sufficient for the elimination of this group from the *Coccygomorphæ*), yet the materials at hand were not sufficient for a perfect account of this type of skull. A fellow-worker has had fuller opportunities.[3] Like the Parrots, these birds form a relatively small and neat group; the most outlying forms are *Picumnus* and *Yunx*, but these form no obstruction to their classification. Mr Parker's proposed morphological term for these birds is *Saurognathæ*, and the two terms can be superimposed, *Celeomorphæ* being their zoological name. Professor Huxley saw that these birds were not desmognathous; that their vomerine moieties remained distinct; that their maxillopalatines are but little developed; and that supernumerary bones on the inner edge of the palatines in *Picus minor* corresponded to the curious bars that are seen in the larger kinds. He also, with quick insight, says that their palate exhibits a "degradation and simplification of the Ægithognathous structure." This is strictly true; the elementary parts are the same, but in the Woodpeckers they retain a very *Reptilian* distinctness, and even arrest of growth. Yet with that arrest there is combined a modification and metamorphosis of certain parts, such as is undergone by no other type. They are in some respects the most simple and embryonic, and in others the most highly specialized birds in the whole class. Their basi-pterygoids are arrested; their basi-temporal region large and wide. Two or three tympanics on each side help to form their remarkable *cowrie-shaped* ear-drum, which is mainly built up by the basi-temporals and exoccipitals. The lower end of the quadrate has the usual form; the bone itself is short; the pterygoids are long, slender, angular, and forked; the lower and foremost fork is the meso-pterygoid element, which does not become segmented off, and thus their pterygoids answer to that of a Snake or Lizard, and reach to the vomer.[4]

The palatines (fig. 27, *pa.*) have their postero-external

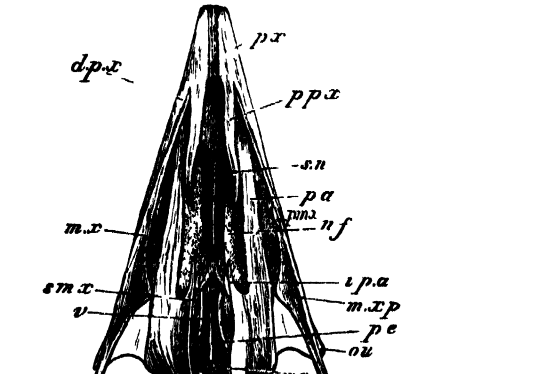

FIG. 27.—Palatal view of skull of a nestling of *Picus minor*, × 4 diameters. *i.pa.*, inter-palatine spur; *s.mx.*, septo-maxillary; *m.pa.*, medio-palatine.

[1] There is not space here to give illustration of all these details: but papers by Mr Parker are now (1875) appearing in the *Transactions of the Linnean and Zoological Societies*, in which these structures are copiously illustrated.

[2] Professor Huxley (*op. cit.*, p. 472) was as unfortunate in his specimens of *Menura* as in that of *Trochilus* (see p. 468, where these birds are said to have their vomer truncated, whereas it is *spiked*); for in Mr Garrod's specimens of the Lyre-bird's skulls the maxillopalatines are large bony plates, like those of ordinary *Coracomorphæ*. The vomer of *Menura* is exactly like that of the Chough (*Fregilus graculus*), and also of many *young Coracomorphæ*, for the two moieties do not necessarily form a re-entering angle or notch in front; that is often largely due to the osseous growth creeping into the alinasal cartilages. *Menura* has one character of great importance, viz., it retains the super-orbital chain of ossicles, like *Psophia* and the *Tinamidæ*.

[3] See Mr Parker's paper "On the *Picidæ*," in the *Linnæan Transactions*, 1875, series 2, vol. i. plates 1-5.

[4] See Günther "On *Hatteria*," *Phil. Trans.*, 1867, plate 1, fig. 2, p. 5.

angle either rounded or obtuse-angled. The post-palatine region is bevelled off remarkably; but in *Picumnus minutus*, the lips of this part are greatly developed, as in the lower Passerines of South America;[1] but in them this marked region appears to be always ossified directly from the main bone, whilst in *Picumnus* it is a separate ossification—a perfectly unique thing, as far as the writer's knowledge goes. The broad main part of the palatine suddenly narrows at its first third, the remaining two-thirds being the long splintery prepalatine, opposite the beginning of which the inner lip runs into an "inter-palatine" spike (*i.pa.*) The ethmo-palatine processes are extremely long in the nestling of *Yunx*, and very short in that of *Picus minor* (*e.pa.*) They are the free anterior ends of that ascending plate which lies under the parasphenoidal rostrum. These plates are united by a cartilaginous commissure, dagger-shaped, which ossifies as the most marked medio-palatine (*m.pa.*) seen in the class. The prepalatine band passes between the dentary and palatine spurs of the premaxillary (*px.*), as in the adult fowl. Oddly enough, they run on the inner side of the palatal process of the premaxillary in most of the *Ægithognathæ*. This is an after-modification, for in the young of *Struthio camelus* and *Gallus domesticus* the fore-end of the one and the hinder end of the other process are broad, and the two unite by suture. In the higher birds the processes overlap on either side, but orderly as to natural groups. The free end of the premaxillary palatine process looks backward to the free inter-palatine spur in the young (fig. 27); but in old birds, as may well be seen in *Gecinus viridis*, *Picus analis*, and *P. major*, these parts are formed into delicate bridges of bone, which also are thrown along to the ethmo-palatines. This is done by the vomerine series. The "septo-maxillaries" are not single conchoidal plates of bone, as in the Snake and Lizard; but are broken up into grains, which melt into each other again. Even the vomer itself is double on each side in *Gecinus viridis*, whilst in *Hemilophus fulvus* there are three septo-maxillaries on the left side and five on the right. These ossicles lie on the inner side of the palatines, and are normally connected behind by means of the vomer to the ethmo palatine; where *normal ornithic ankylosis* takes place in adult birds, there these curious length-wise bridges are formed. Yet this is only part of their complexity, for median septo-maxillaries appear, two of them in *Gecinus*, and these are found in the substance of long, right and left, *labial cartilages*. These do not ossify in *Hemilophus*, but unite at the mid-line; in *Gecinus* they overlap largely to gain the mid-line. In the same species, to add to the complexity, a large shell of bone, from the *inturned alinasal wall*, becomes more or less free of its own origin, and unites to the vomerine series. All this has been seen and explained by writing and by figures.[2]

The maxillo-palatine processes scarcely grow inwards at all in *Picumnus*; in *Yunx* they are rather larger; larger still in *Picus minor* (fig. 27, *mx.p.*) Where they are largest, as in *Gecinus*, they just rest upon the outer edge of the palatines, covering nearly half their width. In all, the under face of the maxillary has an open pneumatic space at this part. But, as if to fill up that which is wanting, a separate palatine plate appears on the inner edge of the maxillary further forward, *only on the left side*, however (fig. 27, *p.mx.*) This is a semi-oval wedge of bone, and has its symmetrical counterparts in several families of the *Coracomorphæ*, viz., *Emberiza*, *Cardinalis*, &c.

These birds are saurognathous in other respects, *e.g.*, their nasal labyrinth is unusually simple. The "inferior turbinal," which has *three* coils in *Rhea* and *Tinamus*, and *two* in most birds, is in *Gecinus* merely bi-alate; in *Yunx* it makes less than a single turn, whilst the alinasal turbinal of that bird has two turns, and that of *Gecinus* one. *Gecinus* is in all respects the most specialized, *Picumnus* the most embryonic, and *Yunx* the most passerine of the *Celeomorphæ*. Also, in *Gecinus* the nasal labyrinth is most ossified, and in *Yunx* least. In *Gecinus* the "columella auris" has two supra-stapedial spurs and two infra-stapedial bands, which have united with the tongue-shaped stylo-hyal: this has in it a bony centre. The small cerato-hyals early coalesce into one arrowhead-shaped bone, and then comes a very long, highly ossified, and elastic basi-hyal, with no uro-hyal behind it. Joined to this are a pair of lower thyro-hyals, half its length; but the upper pieces are four times the length of the lower, and they, passing first down the sides of the upper part of the neck, again turn gently upwards and forwards, ploughing themselves a furrow on the skull top, and deflecting gently to the right nasal roof, where they end.

All these things being considered, it will seem contradictory now to assert the great uniformity of the skulls of Birds, and indeed of the Birds themselves. Yet so it is; and the countless modifications that offer themselves for observation are gentle in the extreme. One form often is seen to pass into another by almost insensible gradations. One thing is certain, namely, that an anatomist not familiar with this class, and coming to its study fresh from the Reptiles, would find himself at fault at every turn; for he would see changes altogether as great as if he had passed from the Helminthoid types, and from mere *larvæ* and *pupæ* of the Insects to the (to him supposably) unthought-of *imagines* that spring from those low and worm-like stages.

In the rest of the Birds' organization abundant evidence of the same specialization will be seen. The mind fails to desire more beauty or to contemplate more exquisite adaptations. An almost infinite variety of Vertebrate life is to be found in this class. Of its members some dig and bury their germs, which rise again in full plumage, whilst others watch and incessantly feed their tender brood in the shady covert or "on the crags of the rock and the strong place." In locomotion some walk, others run, or they may wade, swim, plunge, or dive, whilst most of them "fly in the open firmament of heaven."

THE VERTEBRAL COLUMN, RIBS, AND STERNUM.[3]

The spinal column of birds contains numerous and well-ossified vertebræ, a considerable number of which (more than six) are ankylosed together to form a sacrum. Of the vertebræ which enter into the composition of this complex bone, however, not more than from three to five can be regarded as the homologues of the sacral vertebræ of a Crocodilian or Lacertilian Reptile. The rest are borrowed, in front, from the lumbar and dorsal regions; behind,

Soc.*, Dec. 8, 1863; "On the Osteology of *Microglossa alecto*," *ibid.*, Feb. 28, 1865; "On the Osteology of the Kagu (*Rhinochetus jubatus*)," *Trans. Zool. Soc.*, vol. vi. Huxley "On the Classification of Birds," *Proc. Zool. Soc.*, April 11, 1867; "On the Alectoromorphæ," *ibid.*, May 14, 1868; "The Anatomy of Vertebrate Animals," 1871, p. 272. M. Edmond Alix, *Essai sur l'Appareil Locomoteur des Oiseaux*, Paris, 1874,—a most important work. The writer will often use the "very words" of Professor Huxley, despairing, as he does, of coming near that excellent writer, either in *condensation* or *order*. The working student will find the axial skeleton of the Ostrich most profusely and beautifully illustrated in Professor Mivart's paper (*Trans. Zool. Soc.*, vol. viii. part 7). Every ornithologist will be grateful for that piece of work.

from the tail. The cervical region of the spine is always long; and its vertebræ, which are never fewer than eight, and may be as many as twenty-three, are, for the most part, large in proportion to those of the rest of the body.

The atlas is a relatively small, ring-like bone; and the transverse ligament may become ossified and divide its aperture into two—an upper for the spinal cord, and a lower for the odontoid process of the axis vertebra. The *os odontoideum* is always ankylosed with the second vertebra, and constitutes a peg-like odontoid process.

The spines of the succeeding cervical vertebræ are often obsolete, and are never very prominent in the middle region of the neck. The anterior faces of their elongated vertebral centra are *convex from above downwards*, and *concave from side to side*; whilst the posterior faces are cylindrical, slightly excavated *from above downwards*, and *convex from side to side*. (The contrary of this is stated in Professor Huxley's *Verteb. Anim.*, p. 276, where the author, by a *lapsus memoriæ*, puts it *vice versa*.) Hence, in vertical section the centra appear *opisthocœlous*; in horizontal section, *procœlous*, and not the contrary, as is stated by our author; and the structure is exceedingly characteristic of birds. The under surfaces of the centra frequently give off median inferior processes. In the *Ratitæ* it is obvious that the cervical vertebræ have short transverse

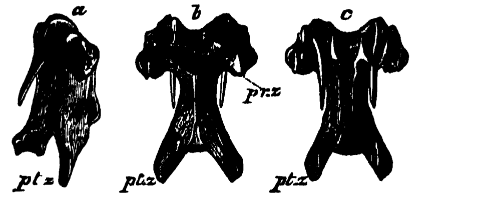

FIG. 28.—A cervical vertebra from the middle of the neck of a *Fowl*; natural size. *a*, side view, *b*, upper view; *c*, lower view, *pr.z.*, pre-zygapophyses; *pt.z.*, post-zygapophyses.

processes and ribs, disposed very much as in the *Crocodilia*. For, in young birds, the anterior end of the lateral face of each vertebra bears two small processes, an upper and a lower; and this expanded head of a styliform rib is articulated with these by two facets, which represent the capitulum and the tuberculum (Huxley, *op. cit.*, p. 276). In the chicken of the Emeu (*Dromæus novæ-hollandiæ*) the writer, in 1843, carefully worked out and figured these parts. Of the twenty cervical vertebræ only the atlas and axis were devoid of distinct ribs; this individual was six weeks old. These riblets were bony wedges, with a sharp point; but that was free, and the thick upper end was jammed in between upper and lower transverse processes (*diapophysis* and *parapophysis*). The last but one of the ribs became suddenly larger, and the last was two-thirds the size of its successor—the first dorsal. Then followed six large ribs on each side, the last two floating. The vertebra bearing the last of these, and twenty more, are closely embraced by the fore-and-aft growth of the ilium, and form the so-called sacrum. Of the twenty vertebræ between the first overlapped bone with a floating rib and the nine *ribless* caudals, there are five with free ribs, small, and hatchet-shaped, quite like those in the neck of the Crocodile. These, from being attached to a parapophysial cup near the fore-end of the centrum, get more forward, and wedge in between their own vertebra and the one in front. The next four vertebræ, which give exit to the sacral plexus (or at least to most of it), have no ribs, and are very broad and short. They develop lamellar upper transverse processes, but their spines are aborted. Then come eleven vertebræ, in front of the free caudal, that have short ribs; the first two pairs are ankylosed already, then *four pairs* are distinct, and the remaining five have their ribs ankylosed, and then becoming shorter and more pedate externally, get further backwards on the centrum. Thus, in a Bird as old as six weeks after hatching, there are eighteen pairs of cervical, and nine pairs of so-called sacral ribs still distinct. Moreover, the ribs are quite aborted on the first and second cervical, on the four *true* sacral,—perchance, the next after this is also sacral,—and on all the caudal vertebræ which have only papilliform transverse processes. There are fifty-five vertebræ in all in the Emeu, thus:—cervical, twenty; dorsal, five; dorso-lumbar (the first with a large rib and really the sixth dorsal), six; sacral (proper), four; uro-sacral, eleven; caudal, nine. We shall return to these data in describing the sacrum of the Fowl.

With age the cervical ribs (of the *Ratitæ*) may become completely ankylosed. In *Apteryx australis* one, below, remains free; in *Struthio camelus*, two; and in *Dromæus novæ-hollandiæ*, three; and then they appear like transverse processes, perforated at the base by a canal, which, as in the *Crocodilia*, contains the vertebral artery and vein, and the main trunk of the sympathetic nerve. The cervical ribs and transverse processes are similarly disposed in very young *Carinatæ*; but in these birds their form frequently becomes much modified in the adult, and they develop prolongations which extend downwards and inwards, and protect the carotid artery or arteries. The neural arches have well-developed pre- and post-zygapophyses. The ribs of one or two of the posterior cervical vertebræ become elongated and freely movable in the *Carinatæ*, as in the *Ratitæ*.

The first dorsal vertebra is defined as such by the union of the ribs with the sternum by means of a sternal rib, which not only, as in the *Crocodilia*, becomes articulated with the vertebral rib, but is converted into complete bone, and is connected by a true articulation with the margin of the sternum. The number of the dorsal vertebræ (reckoning under that head all the vertebræ, after the first dorsal, which possess distinct ribs, whether they be fixed or free) varies. The centra of the dorsal vertebræ either possess cylindroidal articular faces, like those of the neck, as is usually the case; or more or fewer of them may have their faces spheroidal, as in the Penguins [Plovers (and their kin *Vanellus cristatus*, *Totanus fuscus*, &c.), Gulls, Cormorants, and Parrots]. In this case the convex face is anterior, the concave, posterior. They may, or may not, develop inferior median processes [which may be simple, as in the Cormorant, where they exist on several lower cervical, on all the dorsal, and in five sacro-lumbar; or they may bifurcate into two broad, bony leaves, as in *Colymbus*]. They usually possess well-marked spinous processes [which begin in the two or three lower cervicals]. Sometimes they are slightly movable upon one another [bound strongly, in many cases, by ossified tendons of great strength and elasticity]; sometimes they become ankylosed together into a solid mass. [When this takes place the last cervical is ankylosed to the three first dorsal, as in the fowl, the fourth remaining free, and the fifth coalescing with the lumbar; or, as many as *five* may ankylose together, leaving one free, and the last ankylosed to the lumbar, as in *Falco æsalon*. But this number often differs with age, as may be seen in different individuals of *Psophia crepitans*, and other, more typical, Cranes.]

It is characteristic of the dorsal vertebræ of Birds that the posterior, no less than the anterior, vertebræ present a facet or small process on the body, or lower part of the arch, of the vertebra for the capitulum of the rib, while the upper part of the neural arch gives off a more elongated process for the tuberculum. Thus, the transverse processes of all the dorsal vertebræ of a Bird resemble those of the two anterior dorsals of a Crocodile, and no part of the vertebral column of a Bird presents transverse processes with a step for the head of the rib, like those of the

great majority of the vertebræ of *Crocodilia*, *Dinosauria*, *Dicynodontia*, and *Pterosauria*. [The triangular facets for the tubercular processes are scarcely scooped; those for the capitular are neat, round, shallow cups.] The discrimination of the proper lumbar, sacral, and anterior caudal vertebræ, in the ankylosed mass which constitutes the so-called "sacrum" of the Bird, is a matter of considerable difficulty. The general arrangement is as follows:—The most anterior lumbar vertebra has a broad transverse process, which corresponds in form and position with the tubercular transverse process of the last dorsal. In the succeeding lumbar vertebræ the process extends downwards; and in the hindermost [the *third*] it is continued from the centrum, as well as from the arch of the vertebra, and forms a broad mass which abuts against the ilium.[1] This process might well be taken for a sacral rib, and its vertebra for a proper sacral vertebra. But, in the first place, I find no distinct ossification in it [there are *five* of these lumbar vertebræ in the Emeu, two more than in the Fowl, and they all have distinct ribs; and the *ribless* vertebræ are five in the Fowl and four in the Emeu]; and, secondly, the nerves which issue from the intervertebral foramina in front of and behind the vertebra enter into the lumbar plexus, which gives origin to the crural and obturator nerves, and not into the sacral plexus, which is the product of the nerves which issue from the intervertebral foramina of the proper sacral vertebræ in other *Vertebrata*. Behind the last lumbar vertebra follow, at most, five vertebræ which have no ribs; but their arches give off horizontal, lamellar processes, which unite with the ilia. [In the Emeu these *four* vertebræ show not the least trace of ribs, and are flat bricks of bone, below, jammed together like the cervical centra of a *Cetacean*.] The nerves which issue from the intervertebral foramina of these vertebræ unite to form the sacral plexus, whence the great sciatic nerve is given off; and I [Professor Huxley] take them to be the homologues of the sacral vertebræ of the *Reptilia*. The deep fossæ between the centra of these vertebræ, their transverse processes, and the ilia, are occupied by the middle lobes of the kidneys. If these be the true sacral vertebræ, it follows that their successors are anterior caudal. They have expanded upper transverse processes, like the proper sacral vertebræ; but, in addition, three or four of the most anterior of these vertebræ possess ribs, which, like the proper sacral ribs of Reptiles, are suturally united, or ankylosed proximally, with both the neural arches and the centra of these vertebræ; while, distally, they expand and abut against the ilium. The ankylosed caudal vertebræ may be distinguished as *uro-sacral*.

FIG. 20.—The "sacrum" of a young *Fowl*; natural size, seen from below. *d.l.*, dorso-lumbar, *s*, sacral, *c*, caudal vertebra.

We now give a table showing the number of bones in the so-called sacrum of Birds—so many vertebræ as are covered by the ilia and ankylosed together. Here the distinction between *dorsal* and *lumbar* is, that the former possess elongated ribs; and the table will show forms of extreme *length* and of extreme *shortness*, for a Bird; and also, as in the Fowl, of a medium type. Most of the instances are derived from the sacral bones of young Birds.

	d.	l.	s.	u.s.		Total.
Dromæus novæ-hollandiæ .	1	5	4	11	=	21
Cygnus olor	2	5	4	10	=	21
Colymbus glacialis and *C. septentrionalis* .	2	3	5	7	=	17
Gallus domesticus.............	1	3	5	6	=	15[2]
Alcedo ispida.....	1	2	4	6	=	13
Upupa epops........	1	2	3	5	=	11
Cypselus apus	2	1	3	5	=	11

In both the Hoopoe and the Swift the first of these sacrals has an outstanding rib-process. In the Swift the rib on the second of the enclosed dorsals is very long, and its flanking rib nearly reaches the sternum. The next or third vertebra, the lumbar, has *below* it, neither reaching to it above, nor by its sternal piece to the sternum below, another rib; it is two-thirds the size of its predecessor, and only occurs on the *right* side. This will show how, by gradations the most gentle, the vertebræ and their ribs are specialized in each particular type, and also how very arbitrary is our nomenclature.

The Swan has eight free vertebræ behind the *uro-sacral*, and as the last of these is in these types composed of ten vertebræ originally, there are primarily twenty-seven vertebræ in the Swan's tail. The caudal vertebræ which succeed the *uro-sacral* may be numerous and all distinct from one another, as in *Archæopteryx*, or few and distinct, as in *Rhea*; but more generally, only the anterior caudal vertebræ are distinct and movable, the rest being ankylosed into a ploughshare-shaped bone or *pygostyle*, which supports the tail feathers and the uropygial gland, and sometimes, as in the Woodpecker and some other Birds, expands below into a broad polygonal disk.

The centra of the movable presacral vertebræ of Birds are connected together by fibro-cartilaginous rings, which extend from the circumference of one to that of the next. Each ring is continued inwards into a disk, with free anterior and posterior faces—the *meniscus*. The meniscus thins towards its centre, which is always perforated. The synovial space between any two centra, is, therefore, divided by the meniscus into two very narrow chambers, which communicate by the aperture of the meniscus. Sometimes the meniscus is reduced to a rudiment; while, in other cases, it may be united, more or less extensively, with the faces of the centra of the vertebræ. In the caudal region the union is complete, and the meniscus altogether resembles an ordinary intervertebral cartilage.

A ligament traverses the centre of the aperture of the meniscus, and in the Duck contains the intervertebral portion of the notochord. As Jäger[3] has shown, it is the homologue of the odontoid ligament in the cranio-spinal articulation, and of the pulpy central part of the intervertebral fibro-cartilages in *Mammalia*. All the vertebral ribs in the dorsal region, except, perhaps, the very last free ribs, have widely separated capitula and tubercula. More or fewer have well-ossified uncinate processes attached to their posterior margins, as in the *Crocodilia* [and *Hatteria*]. These are separate, both as cartilage and as bone, at first; we have only failed to find them in the Crested Screamer (*Chauna chavaria*). Among the *Ratitæ* they are very small and few in number; in the Emeu and in the Apteryx they are large; they evidently correspond with the unsevered rib-flaps of the little Ant-eater (Parker's *Shoulder-*

[1] It would be more proper to say that ossification extends into and from the centrum as well as from the neural arch. The process, like other processes, exists before the centrum is differentiated from the arch by ossification (Huxley).

[2] Professor Huxley's figure (80, p. 278) only shows *five* uro-sacral, there are *six* in the Fowl.

[3] "Das Wirbelkörpergelenk der Vogel," *Sitzungsberichte der Wineer Akademie*, 1858.

girdle and Sternum, plate 22, figs. 19, 20).] The vertebral ribs are completely ossified up to their junction with the sternal ribs.

The Sternum, Limb-girdles, and Limbs.[1]

The sternum in Birds is a broad plate of cartilage which is always more or less completely replaced in the adult by membrane bone.[2] It begins to ossify by, at fewest, two centres, one on each side, as in the *Ratitæ*. In the *Carinatæ* it usually begins to ossify by five centres, of which one is median for the keel, and two are in pairs for the lateral parts of the sternum. Thus the sternum of a Chicken is at one time separable into five distinct bones, of which the central keel-bearing ossification (fig. 30) is termed the

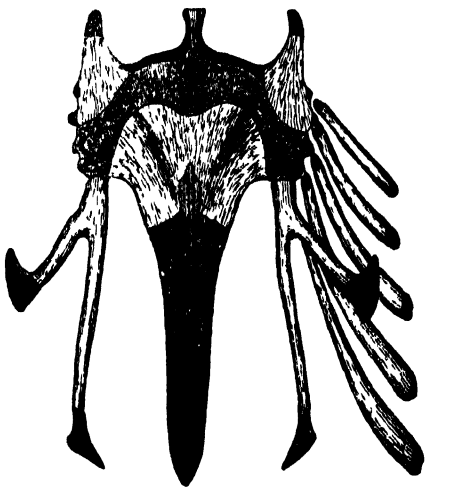

Fig. 30.—Sternum of a Chick (*Gallus domesticus*) three days old, lower view, × three diameters. The cartilage is shaded and dotted, and the bony centres are light and striated. The front external processes are the "costals," and are ossified each by a *pleurosteon*; the median front process is the rostrum, and on each side of it are seen the coracoid grooves. The fore-part of the middle, most of which is carinate, is ossified already by the *lophosteon*; the forked xiphoids on each side are each largely occupied by a *metosteon*; on the right side the sternal ribs are shown.

lophosteon, the antero-lateral piece which articulates with the ribs, *pleurosteon*, and the postero-lateral bifurcated piece, *metosteon*.

[In *Turnix* there are two more centres, mesiad of the pleurostea, these are the *coracostea*; in *Dicholophus* the median part suddenly dilates, behind, into a heart-shaped flap of cartilage, which has an endosteal patch, the *urosteon*.]

Though the sternum, in most Birds, seems to differ very much in form from that of the *Reptilia*, it is rhomboidal in the *Casuariidæ*, where it differs from the Reptilian sternum chiefly in the greater proportional length of its posterior sides, the absence of median backward prolongations, and the convexity of its ventral surface. But in other Birds, and notably in many *Carinatæ*, the antero-lateral edges, which are grooved to receive the coracoids, form a much more open angle than in the *Reptilia*, while the postero-lateral edges become parallel or diverge; and a wide, straight, or convex transverse edge takes the place of the posterior angle. Two, or four, membranous fontanelles may remain in the posterior moiety of the sternum when ossification takes place, and give rise to as many holes, or deep notches, separating slender processes in the dry skeleton. All these correspond with so many divisions of the xiphoid process of the sternum in *Mammalia*, and hence are called *middle*, *internal*, and *external xiphoid processes*. Sometimes a median process, *rostrum* or *manubrium* (figs. 30, 31), is developed from the anterior angle of the sternum, and its antero-lateral angles are developed into *costal processes*, which may bear the articular surfaces for more or fewer of the ribs. The two last-named structures are very distinct in the *Coracomorphæ*, or Passerine Birds.

Fig. 31.—A side view of the Chick's sternum, showing the perforation through the rostrum, and the depth and apiculation of the keel. The external and internal (posterior) "xiphoid processes" are seen to end in pedate expansions. In this, as in the lower view, the great size of the "notches" is shown.

The extent to which the keel of the lophosteon is developed in the Carinate birds varies very much. In *Strigops* it is rudimentary; in birds of powerful flight, as well as in those which use their wings for swimming, it is exceedingly large.

The *pectoral arch* presents a long, narrow, and recurved scapula (fig. 32), without any supra-scapula, and a coracoid

[2] These statements do not apply to *Archæopteryx*; its structure is very imperfectly known (Huxley).

(*co.*), fitted by its proximal end in the groove in the antero-lateral edge of the sternum. The inner ends of the coracoids often overlap, as in *Lacertilia;* otherwise the shoulder-girdle is unlike that of any of the *Reptilia*, except the *Pterosauria.* The coracoid is usually completely ossified, and presents no fontanelle. There is no distinct epicoracoid. The two bones take nearly equal shares in the formation of the glenoidal cavity, and usually remain unankylosed and distinct in this region.

In the *Ratitæ* the long axis of that part of the scapula which lies near the glenoidal cavity is parallel or coincident with that of the coracoid, and the two bones become completely ankylosed. But in all the *Carinatæ* the long axis of the scapula forms an acute, or only slightly obtuse angle (*Ocydromus*, *Didus*) with that of the coracoid. A small bone, the *scapula accessoria*, is developed on the outer side of the shoulder-joint in most *Coracomorphæ* and *Celeomorphæ*.

In the *Carinatæ* the glenoidal end of the scapula is divided into two portions: a *glenoidal* process, which expands to form the upper part of the glenoidal cavity, and to unite with the coracoid; and an *acromial* process, which gives attachment to the outer end of the clavicle. The glenoidal end of the coracoid is in like manner divided into two portions: a *glenoidal* process, which unites with the scapula, and a *clavicular* process, which articulates with the outer surface of the clavicle near its outer end. The clavicular process of the coracoid does not represent the procoracoid of *Lacertilia;* rudiments of that bone unite with the clavicle. In the *Ratitæ* there is no distinct clavicular process; but the anterior part of the coracoid, near the glenoid cavity, may be produced and separated by a notch or fontanelle from the rest, or developed down to the sternum (in *Struthio*) as a lacertilian procoracoid. There is no trace of clavicles in *Apteryx*, *Rhea*, *Struthio*, and some Parrots; but in the latter there is generally an ossified, distinct, short procoracoid. In the Emeu and in some *Carinatæ* (*Didus*, *Rhamphastos toco*, *Corythaix buffoni*, *Buceros albirostris*), the clavicles remain distinct from one another, or connected only by fibrous tissue; but in the majority of Birds they are very early ankylosed together, and with the representative of the inter-clavicle, in the middle line, into a single bone, the *furculum*, the strength of which bears a pretty close relation to the exertion required of the wings in flight or in natation. In the Passerine Birds the scapular end of the clavicle is enlarged by a procoracoid rudiment of cartilage, which ossifies separately, producing the expansion above and in front called *epicleidium.*

A median process (*hypocleidium*) is frequently developed from the inter-clavicular part of the furculum, and this may be united with the carina of the sternum by strong fibrous tissue, or even by continuous ossification. In *Opisthocomus*[1] the furculum is ankylosed with the manubrial part of the sternum on the one hand, and with the coracoids on the other. Ankylosis of the furculum with the coracoids has also been observed in *Didus*,[2] and with both keel and coracoid in *Fregata aquila* (*Shoulder-girdle and Sternum*, p. 15, 1; see also the actual specimen in the museum of Col. Surg. Eng.)

The fore-limb of a Bird, when in a state of rest (fig. 33), exhibits a great change of position, if it be compared with that of an ordinary Reptile; and the change is of a character similar to, but in some respects greater than, that which the arm of a man presents when compared with the fore-limb of a quadrupedal Mammal. The humerus lies parallel with the axis of the body, its proper ventral surface looking outwards. The fore-arm is in a position midway between pronation and supination, and the

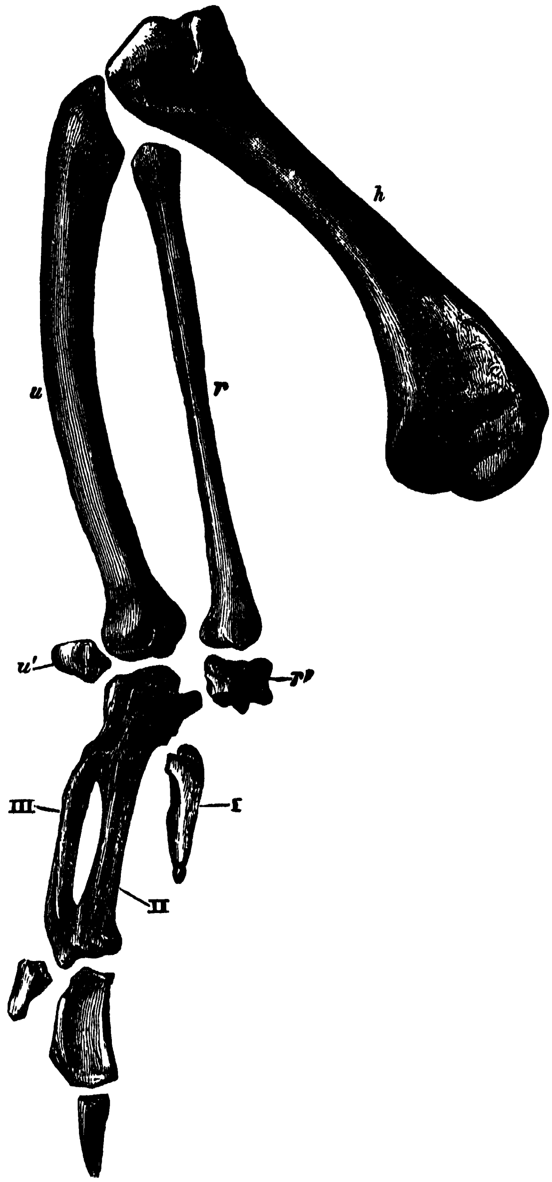

FIG. 33. – Bones of Fowl's right wing, adult, nat. size. *h.*, humerus; *r.*, radius; *u.*, ulnar; *r'.*, *u'.*, radial and ulnar carpal bones; with the three digits I., II., III.

manus is bent back upon the ulnar side of the fore-arm in a position not of flexion but of abduction.

In ordinary Birds the proximal end of the humerus is expanded, and its articular head transversely elongated. Its ventral face is convex, and provided with a strong preaxial ridge, which gives attachment to the pectoral muscle. The proper dorsal face is concave from side to side, especially towards the postaxial margin, where the pneumatic aperture occurs in those birds which have the humerus hollow. The distal end is expanded, and the articular surface for the radius is a convex facet, directed obliquely inwards on its ventral face. In this respect the Bird's humerus exaggerates a feature of that of the Lizard's.

In the *Ratitæ* these peculiarities are very feebly, or not at all, marked, the humerus being a slender, cylindrical, slightly-curved bone. In the *Casuariidæ*, *Dinornithidæ*, and *Apterygidæ*, the fore-limb is extraordinarily reduced, and may become rudimentary. In the Penguins and, to

[1] Huxley "On the *Alectoromorphæ*," p. 306, figs. 8 and 9.

[2] Owen "On the Dodo," *Trans. Zool. Soc.*, vol. vi. part 2, p. 63, plate 20, fig. 4.

a less degree, in the Great Auk, the humerus becomes flattened from side to side, the proximal end is singularly modified, and at the narrow distal end the articular surface for the radius lies completely in front of, and rather above, that for the ulna.

The ulna, which often presents a series of tubercles, indicating the attachment of the secondary quill feathers, is usually a stronger and a longer bone than the radius. There are only two carpal bones, one radial and one ulnar. There is one exception to this, namely, in the Screamer (*Chauna chavaria*), which has three carpals on the left side, the lower arcuate bone having two representatives.

In the *Apterygidæ* and in the *Casuaridæ* there is but one complete digit in the manus. It appears to answer to the second of the pentadactyle limb, and is provided with a claw. In the *Struthionidæ* and *Rheidæ*, and in all the *Carinatæ*, there are three digits in the manus, which answer to the pollex and the second and third digits of the pentadactyle fore-limb; and the metacarpal bones of these digits are ankylosed together. As a rule the metacarpal of the pollex is much shorter than the other two; that of the second digit is strong and straight; that of the third is more slender and bowed, so as to leave an interspace between itself and the second, which is often filled up by bony matter. The pollex has two phalanges, and the second of them is, in many Birds—*Rhea*, the Screamer, &c.—pointed, curved, and ensheathed in a horny claw. The second digit has two and sometimes three phalanges, as in the Swan; and the terminal phalanx is similarly provided with a claw in sundry birds, *e.g.*, the Swan and *Rhea*. In the Ostrich both the pollex and the second digit are unguiculate. The third digit possesses one phalanx, besides its ankylosed metacarpal, and is always devoid of a claw.

It is a singular circumstance that the relative proportions of the humerus and the manus should present the most marked contrast in two groups of birds which are alike remarkable for their powers of flight. These are the Swifts and Humming-birds, in which the humerus is short and the manus long, and the Albatrosses, in which the humerus is long and the manus relatively short.

In the Penguins the pollex has two free phalanges, and its metacarpal bone (which is distinct in the young birds) ankyloses with that of the second digit. The third metacarpal is slender and straight. The bones of the manus are singularly elongated and flattened.

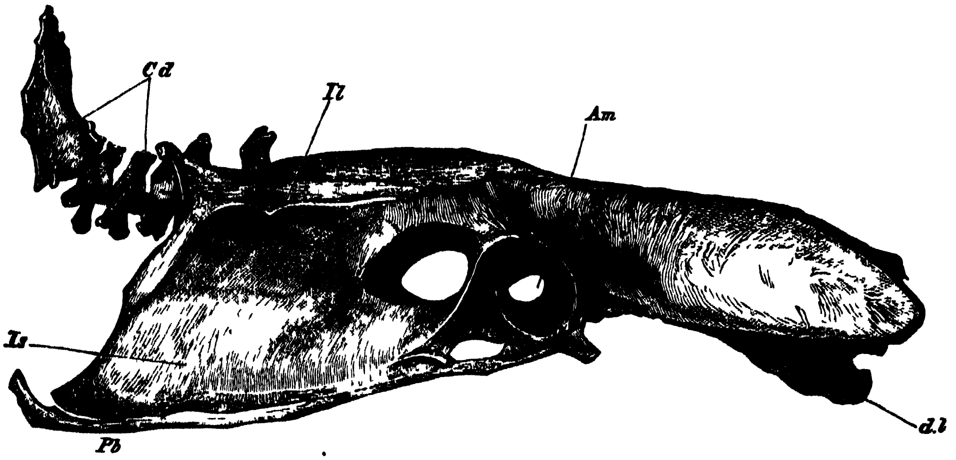

FIG. 34.—Pelvis and caudal vertebræ of adult *Fowl*, side view, natural size *il.*, ilium; *is*, ischium; *pb.*, pubis; *d.l.*, dorso-lumbar vertebra, *cd*, caudal vertebræ; *am*, acetabulum

The *pelvis* of a Bird (fig. 34) is remarkable for the great elongation, both anteriorly and posteriorly, of the iliac bones (*il.*), which unite with the whole length of the edges of the sacrum, and even extend forwards over the posterior ribs of the dorsal region. Below, each iliac bone forms a wide arch over the acetabulum (*am.*), the centre of which is always closed by fibrous tissue, so that in the dry skeleton the bottom of the acetabulum is always perforated by a wide foramen. An articular surface on the ilium, on which the great trochanter of the femur plays, is called the *antitrochanter*. In all ordinary birds the ischium (*is.*), which broadens towards its hinder end, extends back nearly parallel with the hinder part of the ilium, and is united with it by ossification posteriorly. The ischiosciatic interval is thus converted into a foramen. The pubis (*pb.*) enters by its dorsal or acetabular end into the formation of the acetabulum, and then passes backwards and downwards as a comparatively slender, curved bone. nearly parallel with the ischium. It is united with its fellow only by fibrous tissue. Very few birds present a y important variation from this structure of the pelvis. In *Tinamus*,[1] *Casuarius*, *Dromæus*, *Apteryx*, *Dinornis*, the ischium is not united with the backward extension of the ilium by bone. In *Rhea* the ischia unite with one another beneath the vertebral column; and the vertebræ in this region, that is, from the true sacral to the end of the iliac roof, become undistinguishable, being formed into a long slender *uro-sacral* style. In *Struthio* alone, among Birds, do the pubes unite in a median ventral symphysis (see Mivart, *T. Z. S.*, vol. i. part 7, pp. 434, 435, figs. 72, 73). Another not less remarkable circumstance in the Ostrich is that the 31st to the 35th vertebræ, inclusively (counting from the atlas) develop five lateral tuberosities. The three middle tuberosities are large, and abut against the pubis and the ischium. In these vertebræ, as in the dorsal vertebræ of the *Chelonia*, the neural arch of each vertebra shifts forward, so that half its base articulates with the centrum of the next vertebra in front, and the tuberosities in question are outgrowths, partly of the neural arch, and partly of the juxtaposed vertebral centra between which it is wedged. Hence in young Ostriches the face of each tuberosity exhibits a triradiate suture. A small bone is sometimes found on the ventral edge of the pubis, at its middle; this has been supposed to represent a *marsupial bone* (Garrod, *P. Z. S.*, Mar. 1872, p. 359).

The upper articular head of the *femur* is rounded, and its axis is almost at right angles with the body of the bone; a structure which is not found in ordinary *Reptilia*, but exists in the *Iguanodon* and other *Ornithoscelida*. The shaft is relatively short and thick, and the two terminal condyles are large and elongated antero-posteriorly. A prominent ridge, which plays between the proximal ends of the tibia and fibula, is apparent upon the posterior and inferior surface of the outer condyle. A similar ridge is faintly developed in some *Lacertilia*, and is well marked in the Dinosaurian Reptiles. A patella is usually present, but it is sometimes absent, and may be double.

The *fibula* of Birds (fig. 36, *F.*) is always imperfect,

[1] Parker, *Trans. Zool. Soc.*, vol. v. plate 39.

ending in a mere style below. Generally, it is decidedly shorter than the tibia, but it has the same length as that bone in some Penguins. The *tibia* (*t.*), or rather "tibio-tarsus," is a highly characteristic bone. Its proximal end is expanded, and produced anteriorly, into a great *cnemial* process (which may be variously subdivided), as in *Dinosauria*. The distal end is terminated by a well-marked pulley-like articular surface, which is inclined somewhat forwards as well as downwards. Not unfrequently there is an oblique bar of bone on the anterior face, just above the pulley, beneath which the long extensor tendons pass.

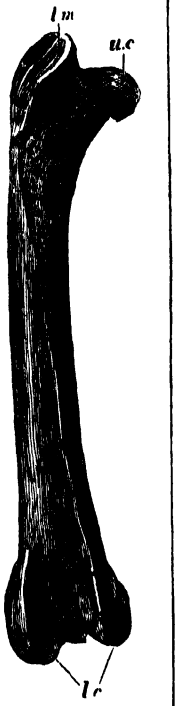

FIG. 35. Right thigh bone of *Fowl*, adult, front view, natural size. *u.c.*, upper condyle; *l.c.*, lower condyles; *t.m.*, trochanter major. The ledge for the fibula on the outside of the outer lower condyle is not seen in this view.

The extremity of the cnemial process in *Struthio*, *Rhea*, and *Dromæus* is ossified as an *epiphysis*; and in young birds the whole of the distal articular end of the bone is separated from the rest by a suture, and also appears to be an epiphysis. But it is, in fact, as Professor Gegenbaur[1] has proved, the proximal division of the tarsus (apparently representing only the astragalus of the other *Vertebrata*), which exists in the embryo as a separate cartilage, and, as it ossifies, ankyloses with the tibia. The so-called tibia of a bird is therefore, properly speaking, a tibio-tarsus.

In all Birds, even in *Archæopteryx*, the fifth digit of the *pes* remains undeveloped;[2] and the second, third, and fourth metatarsals are ankylosed together, and by their proximal ends, with a bone, which is a distinct cartilage in the fœtus, and represents the distal division of the tarsus. Thus a *tarso-metatarsus* is formed (fig. 37). The distal ends of the metatarsals remain separate, and offer convex articular surfaces to the proximal phalanges of the digits.

In the Penguins, large apertures lie between the several metatarsals of the adult *tarso-metatarsus*; and in other birds more or less considerable passages persist between the middle and lateral metatarsals proximally, and the middle and outer distally. In most birds the middle metatarsal does not remain parallel with the others, but its proximal end inclines a little backward, and its distal end a little forward. Hence the two apertures on each side of its proximal end may lie at the bottom of a fossa, or run into one in front, while they remain distinct behind.

Again, in most Birds the posterior face of the proximal end of the middle metatarsal, and the adjacent surface of the tarsal bone, grow out into a process which is commonly, but improperly, termed "calcaneal." The inferior surface of this *hypo-tarsus* is sometimes simply flattened, sometimes traversed by grooves or canals for the flexor tendons of the digits.

When a hallux exists, its metatarsal bone is usually incomplete above, and is united to the ligament by the inner or the posterior surface of the tarso-metatarsus. In the Frigate-bird (*Phaethon*), and in *Steatornis*, the hallucal metatarsal is remarkably long. The genus *Phaethon* stands alone, as far as we know, in having the hallucal metatarsal ankylosed with the others.

In many of the *Alectoromorphæ* a spur (*calcar*), consisting of a bony core ensheathed in horn, is developed on the inner side of the metatarsus, and becomes ankylosed with the metatarsal of the second digit; in some there are

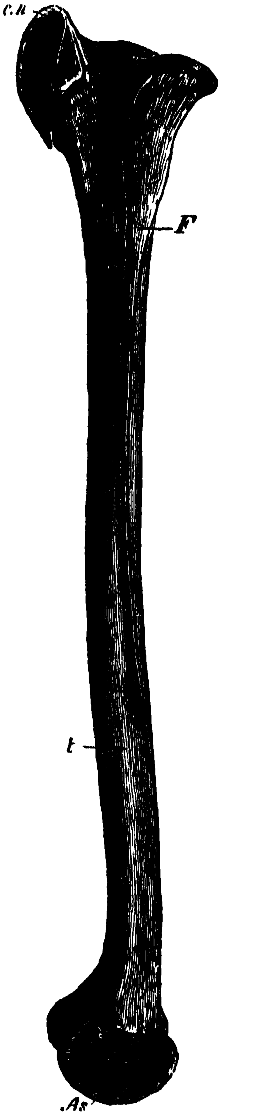

FIG. 36.—Left tibia and fibula of a large young *Fowl*, side view. *t.*, tibia; *F.*, fibula; *As.*, astragalus; *cn.*, cnemial process.

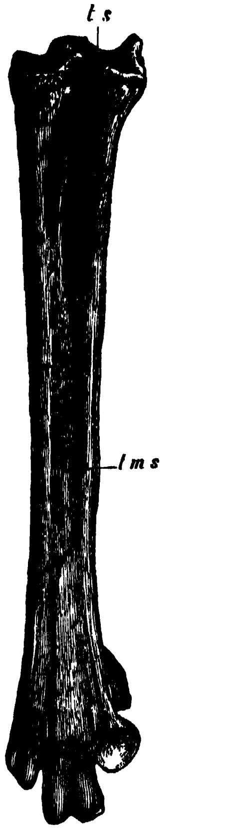

FIG. 37.—Tarso-metatarsi of a large young *Fowl*, front view natural size. *ts.*, tarsal bone; *t m.s.*, triple tarso-metatarsal rod, with the first metatarsal seen below on the right hand, but partly out of view on account of its backward position.

two spurs. In a few birds, similar spurs (Palamedea), or osseous excrescences (*Pezophaps*), are developed in relation with the metacarpus.

The normal number of the pedal phalanges in Birds is (as in ordinary *Lacertilia*) two, three, four, five, reckoning from the hallux to the fourth digit. Among the few Birds which constitute exceptions to the rule are the Swifts, in which the third and fourth toe have only three phalanges each (2, 3, 3, 3), and the Goatsuckers, in which the fourth toe only has the number reduced (2, 3, 4, 4)— not 2, 3, 4, 3, as Professor Huxley (*op. cit.*) puts it for *Caprimulgus*. Mr Parker has figured the fourth toe of the Sand-grouse (*Syrrhaptes*) with only *three*, but he speaks (*op. cit.*, p. 203) of only *one* as wanting in that toe.

Many Birds have only three toes by suppression of the hallux. In the Ostrich, not only the hallux, but the phalanges of the second digit, are suppressed, and the distal end of the second metatarsal is reduced to a mere

[1] See "Archiv. fur Anat.," in *Phys. Jahrgang*, 1863, and Huxley, on "Dinosaurs," *Q. Jour. Geol. Soc.*, Nov. 10, 1869.

[2] In his earlier papers, Mr Parker mistook the bony core of the cock's spur for the first, thus making the proper *hallux* the second toe.

rudiment. Hence the Ostrich has only two toes (which answer to the third and fourth of the pentadactyle foot), with four phalanges in the inner and five in the outer, though the inner toe is far the longer and the stronger.

In most four-toed Birds the hallux is turned more or less completely backwards, and the other three digits forwards. But in many *Aetomorphæ* (especially the Owls) the outer toe can be turned outwards, or even backwards, at will. And in the Parrots, Toucans, Cuckoos, Woodpeckers, and other so-called "Scansorial" Birds, the outer toe is permanently reversed. Under these circumstances the distal end of the outer metatarsal may be divided into two distinct articular surfaces. In the Trogons there are two toes in front and two behind, as in the Parrots; but it is the second toe which is turned backwards. Lastly, in the Swifts, the *Dysporomorphæ*, and the *Spheniscomorphæ*, the hallux is directed more or less forwards, so that all four toes are turned to the front.

As a general rule, the osseous tissue of Birds is remarkably dense and hard. Before hatching, the bones are solid and filled with vascular medulla; but after birth, more or fewer of the bones are always excavated by prolongation of cavities containing air, which lie in their neighbourhood. Such air cavities are always found in the skull, in connection with the nasal and auditory passages, and they may extend through all parts of the skull, with the exception of the jugal arch, which, however, is pneumatic in the Toucan and Hornbill. In many birds, *Apteryx*, Penguin, Divers (and Gulls, according to Professor Huxley; but this is a mistake, their spinal column far into the sacrum is pneumatic; *Larus canus* shows this well), and the smaller Song-birds, no other bones than those of the skull are pneumatic; but in most birds the air-sacs of the lungs send prolongations into the bones of the rest of the trunk-skeleton, seldom into the caudal vertebræ, as in *Balæniceps*, the Adjutant, Hornbill, &c. In the Hornbills the whole skeleton is pneumatic; in a large number of Birds the humerus alone of the limb-bones contains air; in the diurnal *Raptores*, the femur also. It is proper to remark that the amount of pneumaticity of bones by no means follows the development of the powers of flight. In the Ostrich, for example, the bones are far more extensively pneumatic than in the Gull.

In some cases, prolongations of the air-sacs extend beneath the integument.

The Muscles.

In the space allotted to the writer, there is merely room for justice to be done to one category of organs; and as the skeleton, and especially the skull, is of most direct importance to the zoologist and palæontologist, and as its form determines, as it were, all other organs, they being correlated with it and answering to it, it seemed to be that on which election should fall for the fuller treatment. An *impartial* description of all the systems of organs would have resulted in the merest outline for each. For the muscles, Professor Huxley's abstract must serve.[1]

The cutaneous muscles of Birds are well developed, and form broad expansions in various parts of the body. Special bundles of muscular fibres pass to the great quill feathers of the tail and wings, and others to the *patagium*, a fold of integument which stands between the trunk and brachium behind and between the brachium and ante-brachium in front. In correspondence with the slight mobility of the dorsal vertebræ, the episkeletal and hyposkeletal muscles of the spine attain a considerable development only in the neck and in the tail. Owing to the great size of the sternum, the abdominal muscles are usually small, and the internal oblique may be absent. A diaphragm, consisting of bundles of muscular fibre,[2] which pass from the ribs to the aponeurosis, covering the ventral face of the lungs, is developed in all Birds, but attains to the greatest degree of completeness in the *Ratitæ*, and especially in *Apteryx*. The muscles of the limbs are remarkably modified by the excessive development of some of those found in other *Vertebrata*, and the suppression of others.

Thus in all birds possessing the power of flight, the *pectoralis major*, the chief agent of the downward stroke of the wing, is very large and thick, taking its origin from the whole length, and a great part of the depth, of the keel of the sternum. The elevation of the wing is chiefly effected by the *pectoralis secundus* (*levator humeri*; or *p. medius*, Macg., plate 3, figs. 4, 5), which arises beneath (*within* and *over*, in the standing bird) the foregoing muscle, and passes over the inner side of the scapulo-coracoid articulation as over a pulley, to reach the humerus. The muscles of the fore-arm and digits are reduced, in accordance with the peculiar modification of the skeleton of these parts. In the hind limb of most birds there is a singular extensor muscle, which arises from the pubis, and ends in a tendon which passes to the outside of the knee-joint and terminates in the leg by uniting with the *flexor digitorum perforatus*. The result of this arrangement is that the toes are flexed whenever the leg is bent upon the thigh, and consequently the roosting bird is held fast upon his perch by the weight of his own body.[3]

The Brain.

In Birds, as in Reptiles, the cerebro-spinal axis is angulated at the junction of the spinal cord with the medulla oblongata, the latter being bent down towards the ventral side of the body. The region on which the nerves of the anterior and posterior extremities originate is enlarged in Birds. In the lumbar enlargement the posterior columns of the cord diverge and give rise to the *sinus rhomboidalis*, which is a sort of repetition of the fourth ventricle, the dilated central canal of the spinal cord being covered merely by a thin membrane, consisting chiefly of the ependyma and arachnoid. The brain fills the cavity of the skull, and presents a well-developed cerebellum; a mesencephalon, divided above into two optic lobes; and relatively large prosencephalic hemispheres, which attain a considerable size but never conceal the optic lobes. The transverse fissures of the cerebellum are distinct, and the lateral appendages of the cerebellum, or *flocculi*, become well defined, and are wedged, as in many of the lower *Mammalia*, in cavities of the side walls of the skull, arched over by the anterior vertical semicircular canal.

There is no *pons Varolii*, in the sense of transverse fibres connecting the two halves of the cerebellum, visible upon the ventral surface of the mesencephalon. The optic lobes contain ventricles; these are thrown down to the sides of the base of the brain, and are connected over the *aquæductus Sylvii* by a broad commissural band. Each prosencephalic lobe contains a lateral ventricle (continuous through the

[1] *Anat. Vert. Anim.*, p. 300. For an almost exhaustive bibliography of writings on the muscular system of birds, see M. Edmond Alix's *Essai sur l'Appareil locomoteur des Oiseaux*, pp. 367–373. This list begins with Aldrovandus, 1581, and ends with Goverod, 1873, 1874. We miss, however, Macgillivray's excellent description, with figures, of the muscles of flight, *Brit. Birds*, vol. i. plate 3, pp. 35–46; and another by Professor Rolleston, "On Muscles connected with the Shoulder-joint," *Trans. Linn. Soc.*, vol. xxvi. pp. 610–629. See also Owen "On the *Apteryx*," *Trans. Zool. Soc.*, vol. vii. p. 381, pl. 46. But the most important work for reference is that of M. Alix himself (*op. cit.*, pp. 373–471, plates 1–3, "Appareil actif de la Locomotion").

[2] See Macgillivray, *Brit. Birds*, vol. ii. plate 11, fig. 1, *v.v.v.*

[3] See J. Alph. Borelli, *De Motu Animalium*, Romæ, 1680–1682, Lugd. Bat. 1865; and *Bibliotheca Anatomica*, Geneva, 1685, plate 82, figs. 4–7.

foramen of Munro with the third ventricle), which is little more than a fissure between the very thin inner wall of the lobe and its thick outer part, which contains the corpus striatum. The corpora striata are united by an anterior commissure, which is not of large size. The thinning of the inner wall of the lobes, from the margin of the foramen of Munro backwards, which gives rise to the fissure of Bichat in the *Mammalia*, extends for a very short distance in the *Sauropsida*, even in Birds. The olfactory lobes are usually elongated, and contain ventricles continuous with those of the prosencephalic hemispheres. In all the *Sauropsida* the motor nerves of the tongue pass through a foramen in the occipital bone. Hence twelve pairs of cranial nerves are present, except in the *Ophidia*, which possess no spinal accessory nerves. The lateral cutaneous branches, so generally sent to the trunk by the pneumogastric in the *Ichthyopsida*, are absent, but the pneumogastric gives a recurrent branch to the larynx. The third, fourth, and sixth nerves arise quite independently of the fifth. The sympathetic is well developed.[1]

Organs of Sense.

Birds possess nasal glands, which attain a large size, and lie more usually upon the frontal bone, or in the orbits, than in the nasal cavity. In the Snakes and Lizards these bones lie between the septo-maxillaries above and the vomers below. In Birds, wherever placed, the duct opens near the same region as in the Reptiles. In many kinds, especially Passerines, the bones that should cover them are really present, but are rudimentary and attached to the vomer. These are the septo-maxillaries.

The eye in many Birds, as in the extinct *Ichthyosauria*, attains very great absolute and relative dimensions. Birds possess, like many Reptiles, a nictitating membrane.[2] In the Lizards a short, thick muscle (*bursalis*) is attached to the inner and posterior wall of the orbit, and ends in a fibrous sheath. A tendon, one end of which is attached to the presphenoidal region of the inner wall of the orbit, passes backwards through the sheath, and then forwards, to be attached to the nictitating membrane. When the muscle contracts, it necessarily pulls the latter over the eye. A Harderian gland is always developed, and a lachrymal gland very generally, but not always. In the *Chelonia*, muscular fibres (forming the so-called *pyramidalis* muscle) arise from the inner side of the eyeball, and, arching over it at the optic nerve, are inserted partly into the outer edge of the nictitating membrane, partly into the lower eyelid. The *Crocodilia* have a *pyramidalis* muscle taking the same origin and course; but it sends no fibres to the lower eyelid, its tendon being inserted altogether into the nictitating membrane. The third arrangement, which in a manner brings together the first and the second, is that seen in Birds. A *pyramidalis* muscle, arising from the inner and under surface of the eyeball, soon ends in a tendon which sweeps round the upper and outer surfaces of the sclerotic to the nictitating membrane, as in the Crocodiles. But there is also a *bursalis* muscle, which however arises, not, as in Lizards, from the wall of the orbit, but from the upper surface of the sclerotic itself, whence it passes backwards and ends in a fibrous sheath which encloses the tendon of the *pyramidalis*. The contraction of the muscle necessarily tends to draw the tendon of the *pyramidalis* away from the optic nerve. A tubercle is sometimes developed from the sclerotic above the entrance of the optic nerve, and prevents the tendon of the *pyramidalis* from shifting forwards and inwards. The eyeball is always turned by four *recti* and two *obliqui* muscles. The superior oblique does not pass over a pulley. The *Chelonia* and most *Lacertilia* have a more or less completely developed retractor or choanoid muscle. A ring formed of bony plates is developed in the fore part of the sclerotic in *Lacertilia*, *Chelonia*, *Ichthyosauria*, *Dicynodontia*, *Pterosauria*, and *Aves*; but not in *Ophidia*, *Plesiosauria*, or *Crocodilia*. The iris and *tensor choroidei* contain striated muscular fibres. A pecten is very generally developed. It attains a large size, and becomes much plaited in *Aves*. Even in Birds, the sclerotic is cartilaginous.

In the organs of hearing, also, the Bird is best studied as a culmination of the *Sauropsida*.

Only *Crocodilia* and *Aves* possess a rudiment of an external ear. The *Ophidia* and the *Amphisbænoidea* have no tympanic cavity. In some *Chelonia*, in *Sphenodon*, and in the Chameleons, the tympanic membrane is covered by integument, but a tympanic cavity exists. In *Lacertilia* the tympanic cavities communicate by wide openings with the pharynx; but in *Chelonia*, *Crocodilia*, and *Aves*, the communicating passages, reduced in size, become eustachian tubes. In the *Chelonia* these curve backwards, downwards, and inwards, round the quadrate bones, and open separately on the roof of the mouth. In the *Crocodilia* there are three eustachian tubes—one median, and two lateral. In *Aves* there is but one eustachian aperture, answering to the median of the *Crocodilia*; and, as in the latter group, each eustachian tube usually traverses the osseous base of the skull to join its fellow in the common aperture.

The stapes is a columelliform bone, the outer end of which is attached to the tympanic membrane when the latter is developed, but lies among the muscles when there is no tympanic cavity (Snakes and *Amphisbœnæ*). All *Sauropsida* possess a *fenestra rotunda*, as well as a *fenestra ovalis*; and all have a cochlea, which is never coiled spirally, and is more rudimentary in the *Chelonia* than in other groups. Three semicircular canals, an anterior and a posterior vertical and an external horizontal, are connected with the membranous vestibule. In *Aves*, the anterior vertical canal is very large in proportion to the others, and the adjacent crura of the two vertical canals overlap before they unite with one another.[3]

Alimentary Organs.

Well-developed sub-lingual, sub-maxillary, and parotid glands appear in Birds, and the sub-lingual glands attain an immense size in the Woodpeckers (Macg., *Brit. Birds*, vol. iii. plate 15). The tongue varies greatly, being sometimes obsolete (as in the Crocodile). It is small in the *Totipalmatæ* and in *Balæniceps*. It is generally sagittiform and papillate at the base; but it is thick, and even emarginate in the *Rapaces* (Macg., *Brit. Birds*, vol. iii. plates 19, 20). In the *Picidæ* (*op. cit.*, plate 15), where the hyoid bones are extremely elongated and the tongue prehensible to a marvellous degree, the true lingual part is a small arrow-head, covered with a prickly, horny sheath; these prickles are reverted, like a Snake's teeth.

The alimentary canal of Birds may have several dilata-

[1] See Owen, Art. "Aves," *Cyclop. Anat. Phys.*, pp. 298, 299; Macgillivray, *Brit. Birds*, vol. i. p. 48, and vol. iii. plate 18; Owen "On Brain of *Apteryx*," *Trans. Zool. Soc.*, vol. vii. plates 45 and 46, p. 381. For the development of the Fowl's brain, see Foster and Balfour's *Elem. of Embryology*; see also Huxley, *Anat. Vert. Anim.*, p. 301, figs. 90, 91.

[2] See Macgillivray, *Brit. Birds*, vol. iii. plate 17, p. 146, for excellent figures and descriptions of the Bird's eye; also Owen, article "Aves," *Cyclop. Anat. and Phys.*, p. 303. For its development, Foster and Balfour's work, p. 97. The Bird's eye being a more highly specialized *Reptilian* organ, its condition in the lower types of the *Sauropsida* is also given in the text.

[3] See Macgillivray, *Brit. Birds*, vol. iii. plate 18, figs. 2 and 3, p. 156; Owen, article "Aves," in *Cyclop. Anat. and Phys.*, p. 308, fig. 141. For development, see Foster and Balfour's work, p. 111; Huxley on "Incus and Stapes," p. 398; and Parker, *var. loc.*

tions above the intestine; the latter is divisible into small and large, and the last always terminates in a cloaca. It is invested by a peritoneal coat, which follows the curvatures of the intestine. In most Birds, as in the Crocodiles, the pyloric and cardiac apertures are approximated. In many *Crocodilia* and *Aves* (*e.g.*, *Ardeidæ*) there is a pyloric dilatation before the commencement of the duodenum. In the *Alectoromorphæ*, in Eagles and Hawks amongst the *Aetomorphæ*, and in Pigeons, the œsophagus is enlarged into a "crop." In the latter it is bilobate and symmetrical (Macg., *op. cit.*, vol. i. plate 7).

In the *Crocodilia* and in *Aves* the walls of the stomach are very muscular, and the muscular fibres of each side radiate from a central tendon or aponeurosis. The thickening of the muscular tissue of the stomach attains its maximum in the Graminivorous Birds; and it is accompanied by the development of the epithelium into a dense and hard coat, adapted for crushing the food of these animals. Birds commonly aid the triturating power of this gastric mill by swallowing stones; but the habit is not confined to them, Crocodiles having been observed to do the same thing.[1] Birds are further remarkable for the development of a broad zone of glands in the lower part of the œsophagus, which is usually dilated, and forms a proventriculus, connected by a narrow neck with the gizzard (*gigerium*). In *Sula alba* and *Phalacrocorax carbo*, the writer, long ago, saw this zone to be imperfect. In these birds the gullet is very capacious from the pharynx downwards, but the proventriculus is still more so,—it is a large "paunch."

Some *Ophidia* have a cæcum at the junction of the small intestine with the large; and two such cæca, which sometimes attain a large size, are generally developed in *Aves*. In this class, also, the small intestine not unfrequently presents a cæcal appendage, the remains of the vitelline duct. The writer's drawings show this in *Gallinula chloropus*, *Ardea cinerea*, and *Colymbus septentrionalis*. The duodenum of Birds constantly makes a loop, within which the pancreas lies, as in the *Mammalia*.

The liver in the *Sauropsida* almost always possesses a gall bladder, which is usually attached to the under surface of the right lobe, but in *Ophidia* is removed to some distance from it.

A peculiar glandular sac, the *bursa Fabricii*, opens into the anterior and dorsal region of the cloaca in Birds.[2]

The Heart.

In Birds, the venous and arterial blood currents communicate only in the pulmonary and systemic capillaries. The auricular and ventricular septa are complete (see Owen, "Aves," p. 330), as in the *Crocodilia*; but the right ventricle only gives off the pulmonary artery, the left aortic arch has disappeared, and the right arch (the 4th of that side in the embryo) becomes the most important of all the arches. The septum of the *cavum pulmonale* becomes a great muscular fold, and takes on the function of an auriculo-ventricular valve. At the origin of the pulmonary artery, and at that of the aortic arch, three semilunar valves are developed.

[1] See Sir S. Baker's *Ismailia*, vol. i. p. 295. "The stomach contained about five pounds' weight of pebbles (in a Crocodile 12 feet 3 inches long in its entire length), as though it had fed upon flesh resting upon a gravel bank, and had swallowed the pebbles that adhered." This intrepid traveller seems to be unaware that the Crocodile has a strong gizzard.

[2] Besides copious unpublished materials on this subject from his own dissections, the writer is largely indebted to Macgillivray's most valuable work, so full of illustrations of the digestive organs of Birds; also to Prof. Owen's article "Aves" (*op. cit.*); to Prof. Huxley he owes *form* and *order*. For the development of these parts the reader is still directed to Foster and Balfour's work, as also of the parts yet to be described.

In *Aves* there is no renal portal system, and the anterior abdominal vein opens into the inferior vena cava, close to the heart. Nevertheless, a median trunk, which is given off from the caudal vein, carries a considerable proportion of its blood directly into the hepatic portal system. The pericardium of the Bird is thin, but of a firm texture, and adheres by its external surface to the surrounding air-cells. (Owen, "Aves," p. 330.)

Respiratory and Vocal Organs.[3]

"In Birds there are distinct thyroid, cricoid, and arytenoid cartilages, which may be more or less completely ossified. Sometimes an epiglottis is added.[4] The voice of Birds, however, is not formed in the larynx, but in the *syrinx* or lower larynx, which may be developed in three positions:—1. At the bottom of the trachea, from the trachea alone; 2. At the junction of the trachea and bronchi, and out of both; 3. In the bronchi alone. The syrinx may be altogether absent, as in the *Ratitæ* and the *Cathartidæ* or American Vultures. The commonest form of syrinx is the second mentioned above, or the *bronchi-tracheal* syrinx. It is to be met with in all our common Song Birds, but is also completely developed in many Birds, such as the Crows, which have no song. In its commonest condition this form of syrinx presents the following characters: The hindermost rings of the trachea coalesce, and form a peculiarly formed chamber, the *tympanum*. Immediately beyond this the bronchi diverge, and from their posterior wall, where one bronchus passes into the other, a vertical fold of the lining membrane rises in the middle line towards the tympanum, and forms a vertical *septum* between the anterior apertures of the two bronchi. The anterior edge of this septum is a free and thin *membrana semilunaris*, but in its interior a cartilaginous or osseous frame is developed, and becomes united with the tympanum. The base of the frame is broad, and sends out two cornua, one along the ventral, and the other along the dorsal edge of the inner wall of the bronchus of its side, which in this part of its extent is membranous and elastic, and receives the name of the *membrana tympaniformis interna*.

"The bronchial 'rings' opposite this are necessarily incomplete internally, and have the form of arches embracing the outer moiety of the bronchus. The second and third of these bronchial arcs are freely movable, and elastic tissue accumulated upon their inner surfaces gives rise to a fold of the mucous membrane, which forms the outer boundary of a cleft, bounded on the inner side by the *membrana semilunaris*.

"The air forced through these two clefts from the lungs sets these elastic margins vibrating, and thus gives rise to a musical note, the character of which is chiefly determined by the tension of the elastic margins and the length of the tracheal column of air. The muscles, by the contraction of which those two factors of the voice are modified, are extrinsic and intrinsic. The former are possessed by Birds in general, and are usually two pairs, passing from the trachea to the furcula and to the sternum (Macg., vol. ii. plate 12, fig. 8, *d.d.*, *e.e.*; and vol. iii. plate 15, *m.m.*, *n.n.*) Some Birds possessing a broncho-tracheal syrinx such as has been described, as the *Alectoromorphæ* (see Macg., vol. ii. plate 12, fig. 8, *f.*), *Chenomorphæ*, and *Dysporomorphæ*, have no intrinsic muscles. Most others have one pair, attached on one side to the rings of the trachea above, and to the tympanum, or the proximal bronchial arcs below (Macg., vol. ii. plate 12, figs. 1, 2; and vol. iii. plate 19). The majority of the *Coracomorphæ* (Macg., vol. ii. plates 10, 11) have five or six pairs of intrinsic syringeal muscles, which pass from the trachea and its tympanum to the movable bronchial arcs.[5] The Parrots have no septum, and only three pairs of intrinsic muscles.

"The *tracheal* syrinx only occurs in some American *Coracomorphæ*. The hinder end of the trachea is flattened, and six or seven of its rings above the last are interrupted at the sides, and held together by a longitudinal ligamentous band. These rings are excessively delicate, so that the part of the trachea is in great part membranous. The *bronchial* syrinx occurs only in *Steatornis* and *Crotophaga*.

[3] We shall here give Professor Huxley's excellent abstract of what is known upon this subject up to this time; but the reader is referred to Joh. Müller's work, "Researches on the Comparative Anatomy of the Vocal Organs of Birds," *Berlin Acad.*, June 1845, and *Ann. and Mag. N. H.*, vol. xvii. p. 499. Macgillivray has many excellent illustrations and descriptions of these parts, and the writer followed him step by step many years ago.

[4] For a clear description of the exquisite structure of the tracheal rings in Birds, see Macg., vol. ii. p. 34. They are often thoroughly ossified, and are notched above and below, both before and behind; and alternate ridges allow a marvellous amount of overlapping, the edges being well bevelled; each ring is an ellipse.

[5] Macgillivray (*op. cit.*, vol. ii. pp. 26, 28) was afraid to be thought *overstating* the number of these intrinsic muscles. He understated them, not thoroughly making out their divisional lines.

"In the genus *Cinyxis*, among the *Chelonia*, and in some species of *Crocodilus* (*C. acutus*, *e.g.*), the trachea is bent upon itself. Similar flexures attain an extraordinary development in many Birds, and may lie outside the thorax under the integument (*Tetrao urogallus*, some species of *Crax* and *Penelope*); in the cavity of the thorax (some Spoonbills); under the body of the sternum, in a large chamber hollowed out of the keel (some Swans and Cranes); even in a sort of cup formed by the median process of the furcula (*Numida cristata*). In the Emeu some of the rings of the trachea are incomplete in front, and bound the aperture of an air-sac which lies in front of the trachea. Some Birds (*Aptenodytes*, *Procellaria*) have the trachea divided by a longitudinal septum, as in *Sphargis* among the *Chelonia*. The tracheal tympanum is greatly enlarged in *Cephalopterus*, and in many Ducks, Geese, and Divers; and in these aquatic birds the enlargement is more marked in the males, and is usually symmetrical, the left side being generally the larger."

"In *Aves* the lungs are firmly fixed on each side of the vertebral column, the dorsal surface of each lung being moulded to the superjacent vertebræ and ribs. The muscular fibres of the diaphragm arise from the ribs outside the margins of the lungs, and form the vertebral column, and end in an aponeurosis upon the ventral surface of the lungs. Each bronchus enters its lung nearer the centre than the anterior edge, and, immediately losing its cartilaginous or bony rings, dilates, and then traverses the lung, gradually narrowing to the posterior edge of that viscus, where it terminates by opening into the posterior air-sac, which generally lies in the abdomen. From the inner side of the bronchus canals are given off, one near its distal end, and others near its entrance into the lung, which pass directly to the ventral surface of the lung, and there open into other air-sacs. Of these there are four. Two, the *anterior* and the *posterior thoracic*, lie in the ventral face of the lung in the thorax. The other two are situated in front of its anterior end, and are extra-thoracic. The external and superior is the cervical; the internal and inferior the *inter-clavicular* (Macg., vol. ii., p, 17, fig. 107). This last unites into one cavity with its fellow of the opposite lung. Thus there are altogether nine air-sacs; two posterior or abdominal, four thoracic, two cervical, and one inter-clavicular. Other large canals given off from the bronchus do not end in air-sacs, but those which pass from the inner side of the bronchus run along the ventral surface, and those on the outer side along the dorsal surface of the lung. Here they give off at right angles a series of secondary canals, and these similarly emit still smaller tertiary canals, and thus the whole substance of the lung becomes inter-penetrated by tubuli, the walls of the finest of which are minutely sacculated. The different systems of tubuli are placed in communication by perforations in their walls. In most birds these air-sacs (except the anterior and posterior thoracic, which never communicate with any cavity but that of the lungs) are in communication with a more or less extensively ramified system of air passages, which may extend through a great many of the bones, and even give off subcutaneous sacs. Thus the inter-clavicular air-sac generally sends a prolongation into each axilla, which opens into the proximal end of the humerus, and causes the cavity of that bone to be full of air. When the sternum, the ribs, and the bones of the pectoral girdle are pneumatic, they also receive their air from the inter-clavicular air-sacs. The cervical air-sacs may send prolongations along the vertebral canal of each side; which supply the bodies of the cervical vertebræ, and communicate with elongated air-chambers in the spinal canal itself. When the dorsal vertebræ are pneumatic they communicate with the system of the cervical air-sacs. The abdominal air-sacs send prolongations above the kidneys to the sacral vertebræ and to the femora, whence these bones, when they are pneumatic, receive their air. The pulmonary air-sacs and their prolongations do not communicate with the air cavities of the skull, which receive their air from the tympana and the nasal chambers. In some Birds (*Passerinæ*) the air is conducted from the tympanum to the articular piece of the mandible by a special bony tube, the *siphonium* [the largest of the tympanic chain, and having the general anatomical relations of the ichthyic 'interopercular.']"

Renal and Reproductive Organs.

The kidneys of Birds are composed of a number of lobules of unequal sizes, and these are packed in the concavities of the pelvis, in the same manner as the lungs are packed in the regular intercostal spaces of the upper part of the thorax. The ureters, as in the Reptiles, open directly into the cloaca; but there is no urinary bladder. The *bursa Fabricii* opens into the cloaca above its hinder part.

The testes lie on each side the foremost lobes of the kidneys. They are very small in mid-winter, and largest by the middle of April. In the embryo Bird there are two oviducts. "The duct of Müller on the right side (that on the left side with the corresponding ovary generally disappearing) remains in the female as the oviduct. In the male it is almost entirely obliterated on both sides" (Foster and Balfour, p. 168).

Integument and Feathers.[1]

"The exoskeleton of Birds consists almost entirely of epidermic structures in the form of horny sheaths, scales, plates, or feathers. No Bird possesses dermal ossifications, unless the spurs, which are developed upon the legs and wings of some species, may be regarded as such.

The feathers are of various kinds. Those which exhibit the most complicated structure are called *pennæ* or *contour feathers*, because they lie on the surface and determine the contour of the body. In every penna the following parts are to be distinguished:—a main stem (*scapus*) forming the axis of the feather, and divided into a proximal hollow cylinder, partly embedded in a sac of the derm, called the *calamus*, or quill; and a distal *vexillum*, or vane, consisting of a four-sided solid shaft, the *rachis*, which extends to the extremity of the feather, and bears a number of lateral processes, the *barbs*. The calamus has an inferior aperture (*umbilicus inferior*), into which the vascular pulp penetrates, and a superior aperture (*umbilicus superior*), situated on the under surface of the feather at the junction of the calamus with the scapus. The barbs are narrow plates, tapering to points at their free ends, and attached by their bases on each side of the rachis. The edges of these barbs are directed upwards and downwards, when the *vexillum* of the feather is horizontal. The interstices between the barbs are filled up by the *barbules*,—pointed processes, which stand in the same relation to the barbs as the barbs do to the rachis. The barbules themselves may be laterally serrated and terminated by little hooks, which interlock with the hooks of the opposed barbules. In very many Birds each quill bears two vexilla; the second, called the *after-shaft* (*hyporachis*), being attached on the underside of the first close to the superior umbilicus. The after-shaft is generally much smaller than the chief vexillum; but in some Birds, as the *Casuariidæ*, the two are of equal size, or nearly so. Muscles pass from the adjacent integuments to the feather sac, and by their contraction erect the feather. The other kinds of feathers differ from the pennæ, in having the barbs soft and free from one another, when they constitute *pennoplumæ*, or *plumulæ* (down), according as the scapus is much or little developed. When the scapus is very long, and the vexillum very small or rudimentary, the feather is termed a *filopluma*.

The contour feathers are distributed evenly over the body only in a few Birds, as the *Ratitæ*, the Penguins, and some others. Generally, the pennæ are arranged in definitely circumscribed patches or bands, between which the integument is either bare or covered only with down. These series of contour feathers are termed *pterylæ*, and their interspaces *apteria*.

In some Birds, such as the Herons, plumulæ of a peculiar kind, the summits of which break off into a fine dust or powder as fast as they are formed, are developed upon certain portions of the integument, which are termed *powder-down patches*.[2]

[1] This abstract is taken (by the author's permission) from Professor Huxley's *Anatomy of Vertebrated Animals*, pp. 274, 275. For a full account of these structures, see Nitzsch's *Pterylography*, translated from the German by Dr P. L. Sclater, F.R.S., Ray Soc., 1867.

[2] See Bartlett, "On the Balæniceps," *Proc. Zool. Soc.*, March 26, 1861, pp. 1-4; and Murie "On the Dermal and Visceral Structures of the Kagu, Sun-Bittern, and Boat-Bill," *Trans. Zool. Soc.*, 1871, plate 5↑, pp. 465-492; in this valuable paper the *powder-down patches* are also shown in *Podargus* and *Cacatua*.

The integument of Birds is, for the most part, devoid of glands; but many Birds have a peculiar sebaceous gland developed in the integument which covers the coccyx. This *uropygial gland* secretes an oily fluid, which the Bird spread over its feathers by the operation of "preening." The excretion passes out by one or two apertures, commonly situated upon an elevation, which may or may not be provided with a special circlet of feathers.

In various Birds (*e.g.*, the Turkey) the integument about the head and neck develops highly vascular and sometimes erectile processes (*combs*, *wattles*)."

Within the extremely narrow space of an article like the present, the merest abstract of most of our present ornithotomical knowledge can be given. A mere list of the published works on the subject would fill most of the space allotted to the writer. We will conclude by giving Professor Huxley's masterly comparison of the Bird class and that of the Reptiles below with the Mammalia above them (see *Proc. Zool. Soc.*, April 11, 1867). The writer has modified some assertions from later papers by the same author:—

"That the association of Birds with Reptiles into one primary group of the *Vertebrata*, the SAUROPSIDA, is not a mere fancy, but that the necessity of such a step is as plain and demonstrable as any position of taxonomy can be, appears to me to be proved by an enumeration of the principal points in which *Aves* and *Reptilia* agree with one another and differ from the Mammalia.

"1. They are devoid of hair.

"2. The centra of their vertebræ have no epiphyses.

"3. Their skulls have single occipital condyles.

"4. The prootic bone either remains distinct throughout life, or unites with the epiotic and opisthotic *after* these have become ankylosed with the supra-occipital and exoccipital.

"5. The *malleus* is not subservient to the function of hearing, as [one of the] *ossicula auditus*.

"6. The mandible is connected with the skull by the intermediation of a quadrate bone [which represents the upper bulbous part, with the 'manubrium' of the *malleus* of Mammalia].

"7. Each ramus of the mandible is composed of a number of separate ossifications, which may amount to as many as six in all. (Of these the *articulare* represents the [antero-inferior part of the] *malleus* of Mammalia).

"8. The apparent 'ankle-joint' is situated not between the *tibia* and the *astragalus*, as in the Mammalia, but between the proximal and distal divisions of the tarsus.[1]

"9. The brain is devoid of any *corpus callosum*.

"10. The heart is usually provided with two aortic arches; if only one remains, it is the right.

"11. The red blood-corpuscles are oval and nucleated.

"12. The cavities of the thorax and abdomen are never separated by a complete diaphragm.

"13. The allantois, which is highly vascular, is very large, and envelops the embryo; but no villi for placental connection with the parent are developed upon it.

"14. There are no mammary glands." (W.K.P.)

FOSSIL BIRDS.

Supposed Triassic Birds.

Footprints, or casts of footprints, at the time of their discovery and long afterwards supposed to be those of Birds, were found about the year 1835 in the Triassic formation of the valley of the Connecticut in New England, and were described by Messrs Deane and Marsh. Subsequently Professor Hitchcock and Mr Warren contributed to the elucidation of these tracks, which were ascribed to various genera of the Class that received the names of *Amblonyx*, *Argozoum*, *Brontozoum*, *Grallator*, *Ornithopus*, *Platypterna*, *Tridentipes*, and others. No portion of any of the animals to which these traces are due seems to have been met with,[2] and the best American palæontologists are now inclined to attribute them rather to Dinosaurian Reptiles than to Birds. Whatever may be thought of the rest, it appears most likely that the creatures designated as *Platypterna* and *Tridentipes* were certainly not ornithic. *Brontozoum* must have been a colossal animal, its footprint measuring about 16¾ inches in length and its stride some 8 feet.

Oolitic Birds.

An enormous space of time separates these reputed Ornithichnites, as they are called, from the first undoubted fossil Bird. This was discovered in 1861 by Andreas Wagner in the lithographic slate of Solenhofen in Bavaria, belonging to the Oolitic series, and is commonly known by the name of *Archæopteryx*,[3] though that of *Gryphosaurus*

FIG. 38.—Slab containing remains of *Archæopteryx*, from the original in the British Museum. Reduced.

was given by its original describer to the at present unique specimen now in the British Museum. Unfortunately deficient in some very important parts—such as the head and nearly all the sternal apparatus—it has others in excellent preservation. It was about the size of a Rook (*Corvus frugilegus*), and along with the greater portion of the skeleton, impressions of many of its feathers, particularly the quills, are plainly visible. Its most obvious peculiarity is the presence of a long Lizard-like tail, composed of twenty vertebræ; but from each of these springs a pair of well-developed rectrices. A scarcely less remarkable feature is that afforded by the extremity of the wings, where it would appear that there was a free digit answering to the *pollex*. The many Reptilian characters of this wonderful creature cannot be noticed in this treatise, though their value must be fully admitted; but since the appearance of Professor Owen's description of the specimen (*Phil. Trans.* 1863, p. 33), nobody has hesitated to receive it as a true Bird, though one which exhibits an extraordinary dissimilarity from all other known members of the Class. To make any suggestion as to the more immediate affinities and habits of *Archæopteryx* were vain. It at present

[1] See Gegenbaur, *Archiv für Anatomie* (1863), and *Untersuchungen zur vergleichenden Anatomie* (1864).

[2] The only known bones from this deposit were exhibited by Professor W. B. Rogers at the meeting of the British Association in Bath (*Rep. Br. Ass.* 1864, *Trans. Sect.*, p. 66).

[3] Herr Hermann von Meyer had previously described a fossil feather from the same formation, to the owner of which he gave this name. Its specific, generic, not to say ordinal, identity with the creature whose remains were subsequently found is of course problematical, but the received laws of nomenclature fully justify the common usage.

stands alone, and all that can be said in the latter respect is, that the form of its feet indicates a bird given to a more or less arboreal life. It is not easy to imagine the use in

FIG. 39.—Portion of the slab containing remains of *Archæopteryx*, showing the extremity of the tail, with a pair of feathers springing from each vertebra Natural Size.

the bearer's economy of its singular tail, which one would think must have been a clumsy appendage, and this notion is perhaps justified by the certainty that similar tails had gone out of fashion when the next birds known to have existed flourished.

Cretaceous Birds.

These are from the Cretaceous formation, and as in that freshwater-deposits are few in number, it is not surprising that true ornithic remains are in them exceedingly rare. Many fossils that were formerly thought to have been the remains of Birds have since been determined as belonging to Reptiles (Pterodactyls),—among them the *Cimoliornis diomedea*, from the Chalk of Maidstone, which Dr Bowerbank has not hesitated to refer to his *Pterodactylus giganteus*. But in 1858 Barrett discovered, in the Upper Greensand of Cambridge, remains described by Mr Seeley in 1866 (*Ann. and Mag. Nat. Hist.* ser. 3, xviii. p. 100) under the name of *Pelagornis barretti*,—which, we must bear in mind, has nothing to do with the genus *Pelagornis* established by M. Lartet (*Comptes Rendus*, 1857, p. 740), —and these remains, renamed *Enaliornis* in 1869 by Mr Seeley (*Index to Rep. on Second. Reptiles*, &c.), seem to be those of a real Bird, having some resemblance to a Penguin. Belonging to the same epoch also Bird-fossils have been found by Professor Marsh in the United States of America, and they have been referred to at least six genera—*Apatornis*, *Graculavus* (4 spp.), *Hesperornis*, *Ichthyornis*, *Laornis*, *Palæotringa* (3 spp.), and *Telmatornis* (2 spp.) The first and fourth of these were about as large as a Pigeon, or larger, are from the Cretaceous shale of Kansas, and differ from all known Birds in having biconcave vertebræ and, possibly, teeth, whence the latter has been made the type of a distinct Subclass, to which the name of *Odontornithes* is applied. The second belongs to the *Steganopodes;* the third seems to have been related to the *Colymbidæ*. The affinities of the fifth have not yet been determined; it was nearly as large as a Swan, and its remains were discovered in the Middle Marl of New Jersey. The sixth was apparently one of the *Limicolæ;* and the seventh was probably allied to the *Rallidæ*.

Eocene Birds.

The Eocene period furnished a still greater number of ornitholites. First, perhaps, in bulk is that known as *Gastornis parisiensis*, found by M. Gaston Planté, and soon after by M. Hébert, in a conglomerate beneath the Plastic Clay of Bas-Meudon. Much difference of opinion obtains as to the affinities of this Bird, which was at least as large as an Ostrich; but M. Alphonse Milne-Edwards,[1] after reviewing the evidence of others and studying the specimens obtained, considers it (*Dict. Univ. d'Hist. Nat.* ed. 2, May 1869) most nearly allied to the *Anatidæ*, from which, however, it differs in so many important characters that it cannot be included among them according to any taxonomic scheme as yet proposed. One may presume, he adds, that it was incapable of flight, though able to swim. Other birds of huge stature lived at a time not much later. Dr Bowerbank has referred the fragment of a tibia from Sheppey, which was a little smaller than that of an Emeu, to a genus *Lithornis*. On this Mr Seeley has founded his *Megalornis*, the *Lithornis* to which Professor Owen, in 1841, had applied the former name, being regarded as resembling a Vulture. This naturalist has also described the fragmentary cranium of a large Bird, combining Dinornithic and Struthious characters, from the same locality, under the name of *Dasornis* (*Tr. Zool. Soc.* vii. p. 145), and he has further added from Sheppey (*Quart. Journ. Geol. Soc.* xxix. p. 511) a yet more remarkable form to those previously known from Britain, in the *Odontopteryx toliapicus*—

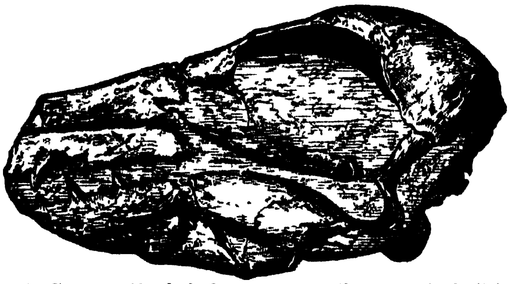

FIG. 40.—Remains of head of *Odontopteryx*, from the original in the British Museum; side view; natural size.

a creature having its jaws armed with osseous denticulations, and in this respect unlike Professor Marsh's *Ichthyornis*,

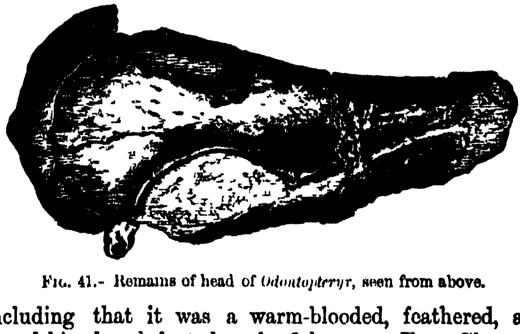

FIG. 41.—Remains of head of *Odontopteryx*, seen from above.

concluding that it was a warm-blooded, feathered, and winged biped, web-footed, and a fish-eater. From Sheppey,

[1] The writer cannot name this distinguished naturalist without acknowledging the very many tokens of friendship received at his hands in connection with the present subject, while the summary of fossil ornithology here given is in a great measure due to the article cited in the text a few lines further on. Further details are taken from his magnificent *Recherches Anatomiques et Paléontologiques pour servir à l'histoire des Oiseaux Fossiles de la France*, Paris, 1867–71. The writer has also to express his thanks to Mr Seeley for valuable assistance in this portion of the article.

too, were long ago detected portions of a Kingfisher (*Halcyon*), and a bird allied to the Gulls or Terns (*Laridæ*), while a continuation of the same formation at Highgate has supplied a sternum which has been referred to the Herons (*Ardeidæ*). The freshwater beds at Hempstead, in the Isle of Wight, have furnished remains called by Mr Seeley (*Ann. and Mag. Nat. Hist.* ser. 3, xviii. p. 109) *Ptenornis*—a form of doubtful affinity; and that palæontologist has described from those of Hordwell a tibia, apparently Struthious, under the name of *Macrornis*. In the schist of Plattenberg at Glarus a nearly complete skeleton, perhaps belonging to the *Passeres*, was discovered, and called by Von Meyer *Protornis* (since renamed by Professor Gervais *Osteornis*), and other undetermined fragments of birds' bones, with impressions of their feathers, have been found in several beds of about the same age in France.

Fig. 42.—Remains of head of *Odontopteryx*, seen from behind.

Paris Basin.

The fossils of the Paris Basin and its coeval deposits deserve, however, fuller notice. First brought to light at Montmartre towards the end of the last century, many of the remains fell under the notice of Cuvier, and were by him determined in a manner more or less exact. Following his investigations, the labours of MM. Gervais, Blanchard, and Desnoyers considerably added to our knowledge of these ornitholites, till finally M. Alphonse Milne-Edwards, having carefully gone over all the specimens discovered, refers them to the genera *Agnopterus*, *Cormoranus* (*i.e.*, *Phalacrocorax*), *Coturnix* (2 spp.), *Falco*, *Gypsornis*, *Leptosomus* (a form now only known from Madagascar), *Limosa*, *Palæocircus*, *Palæortyx*, *Pelidna*, *Rallus*, *Sitta*, and *Tringa* (?). Of these are extinct the first, which seems to have been in some measure allied to the Flamingoes (*Phœnicopteridæ*); the fifth, a Ralline form; and the eighth and ninth, belonging to the diurnal Birds-of-prey and the *Gallinæ* respectively. The footprints of at least seven more species of birds have also been recognised in the same beds, so famed for the remains of *Anoplotherium*, *Palæotherium*, and their contemporaries, which were resuscitated by the great Cuvier. The marl-beds of Aix in Provence, belonging to this epoch, have yielded fossil eggs and feathers, but as yet no bones of Birds; and to the same period must probably also be assigned the lacustrine calcareous deposits of Armissan, in Languedoc, whence M. Gervais has recovered the remains of a *Tetrao*. Near Apt, also in Provence, some traces of birds seem to have been found, but their bad condition has hindered their determination. In the marls of Ronzon, in Auvergne, several ornitholites have been found by M. Aymard, who refers them to the genera *Camascelus*, *Dolichopterus*, *Elornis* (3 spp.), and *Teracus*. Of these the first was declared to be allied to the Plovers (*Charadriidæ*), the second to the Gulls, the third to the Flamingoes, and the fourth to be a Falconine; but M. A. Milne-Edwards considers the first and second to be probably identical. From the same beds M. Gervais has eggs and imprints of feathers, as well as a pelvis, referred by him to *Mergus*, but regarded by M. A. Milne-Edwards as a *Sula*; while Dr Fraas has found remains of a Harrier and a Cormorant on the top of the Swabian Alp. Finally, in North America Professor Marsh has described the remains of no less than five species of birds, varying in size from a Flamingo to a small Woodcock, but all referred by him to a genus *Aletornis*, from the Eocene deposits of Wyoming (*Am. Journ. Sc.* ser. 3, iv. p. 256).

The Miocene formation has yielded by far the greatest number of ornitholites, especially in France, and for want of space they can be barely named here. From lacustrine deposits in Bourbonnais and Auvergne, the remains of nearly fifty species of birds have been distinguished. Besides *Palæortyx*, already mentioned (3 spp.), *Palælodus* (5 spp.), *Pelargopsis*, *Ibidopodia*, *Elornis*, *Hydrornis*, and *Colymboides* are extinct genera to which these fossils are referred. *Palælodus* is perhaps the most remarkable of them—a generalized form, unquestionably allied to the Flamingoes, but presenting some characters of the *Limicolæ*, and at least one feature now only found in *Podiceps* and *Colymbus*. *Pelargopsis* and *Ibidopodia* were Stork-like, while *Elornis* seems to have been Scolopacine; *Hydrornis* must be placed near the Gulls, and *Colymboides* among the Divers. The rest can be referred to the existing genera—*Aquila*, *Milvus*, *Bubo*, *Psittacus* (a very noteworthy fact, since no Parrots are now to be found in the Palæarctic Region), *Picus*, *Motacilla*, *Passer*, *Columba*, *Rallus*, *Phœnicopterus*, *Grus*, *Ibis*, *Totanus*, *Tringa*, *Larus*, *Phalacrocorax*, *Sula*, *Pelecanus*, and *Anas*. A very considerable number of forms identical with these have been recovered from the neighbourhood of Mentz, while many ornitholites, whether fossil bones, foot-prints, or impressions of feathers, are supplied by freshwater formations near Berne, and in Provence and Languedoc, belonging to this epoch. The bone-beds of Sanson, in Gascony, are also very productive. Here we have as extinct forms *Homolopus*, allied to the *Picidæ*, *Necrornis*, which seems to belong to the *Musophagidæ*—a family now limited to Africa—and *Palæoperdix* (3 spp.), a Gallinacean; while among existing genera we have represented *Aquila*, *Haliaetus*, *Strix*, *Corvus*, *Phasianus* (2 spp.)—a genus generally supposed to have been introduced into Europe in historic times—*Rallus*, *Numenius*, *Ardea*, and *Anas*. Passing thence to Greece, the remains of birds have been found at Pikermi in Attica—a *Phasianus*, a *Gallus*—somewhat larger than *G. sonnerati* (the presumed ancestor of our Barndoor-fowl), and a large *Grus*. In the Tertiary deposits of the lower ranges of the Himalaya, the interesting discovery of an apparently true *Struthio* (Ostrich) has been made, with an *Argala*, and possibly a large species of *Phaeton*. From Steinheim, also, but perhaps of a somewhat later period, the remains of eight species of birds (belonging to the genera *Ibis*, *Ardea*, *Palælodus*, *Anas*, and *Pelecanus*) have been determined by Dr Fraas,[1] three of which seem to be specifically identical with those first discovered in France. In the Miocene of North America, Professor Marsh has detected bones of *Meleagris*, *Sula*, *Puffinus*, and *Uria*, all existing genera, but the first is especially suggestive, since it is now one of the most characteristic forms of the New World. From the Lower Tertiary of the same continent he has also described a *Bubo* and an extinct genus *Uintornis*, probably related to the *Picidæ* (*Am. Journ. Sc.* ser. 3, iv. p. 259).

Miocene Birds.

Pliocene Birds.

The Pliocene epoch is far less rich than the preceding in ornitholites, and what have been found are less well determined. In France, the existence of a Bird-of-prey and several Water-birds has been indicated, but a species of *Gallus* from Auvergne seems to be the only form established. At Œhningen, in Baden, remains have been found, and referred to *Scolopax* and *Anas* (probably also to *Anser*), while from Radoboj, in Croatia, the almost entire foot of a bird has been assigned to *Fringilla* by Hermann von Meyer, who has further detected in Germany a fossil humerus, on which he founds a genus *Ardeacites*, allied to the Herons. From the Pliocene of North America Professor Marsh has described remains of an *Aquila*, a *Grus*, and a *Phalacrocorax*.

The Postpliocene of the same continent has rewarded

[1] *Die Fauna von Steinheim*, Stuttgart, 1871.

Postpliocene Birds. the same palæontologist with two more species of *Meleagris*, another *Grus*, and an *Uria*. In Europe, beds of that epoch have not furnished very many ornitholites, while such as are known have been insufficiently studied. A *Gallus*, however, seems to have been found at Paris by M. Gervais, and other portions of the same bird have been recognized from the caves of Aquitaine by M. A. Milne-Edwards. Near Quedlinburg, remains referred to Crows, Sparrows, Swallows, a Bustard, and a Gull, have been recognized, as well as an apparent Vulturine from Magdeburg. Hermann von Meyer has indicated from the valley of the Lahn, Crows, Thrushes, Partridges, and Ducks, as well as a *Numida* from Salzbach. A small Owl, too, has been found at Kostritz. In England, remains of a Swan and a Cormorant have occurred in the diluvial beds of Grays in Essex, and an Owl of middle size in the Norwich Crag, which may, however, be of Pliocene age; while in France the celebrated gravels of St Acheul have supplied a bone believed by M. A. Milne-Edwards to belong to the Grey Lag-Goose (*Anser cinereus*), to which species, also, an egg found in brick earth at Fisherton, near Salisbury, has been referred by Mr Blackmoor, who in the same bed found another egg, supposed to have been that of *Anas boschas* (*Edinb. N. Phil. Journ.* N.S. xix. p. 74).

Cave Birds. A great number of Birds' bones have been discovered in caves, and among them some bearing marks of human workmanship. In France we have first a large and extinct species of Crane (*Grus primigenia*), but more interesting than that are the very numerous relics of two species, the concomitants even now of the Reindeer, which were abundant in that country at the period when this beast flourished there, and have followed it in its northward retreat. These are the Snowy Owl (*Nyctea scandiaca*), and the Willow-Grouse (*Lagopus albus*). But here it seems unnecessary further to particularize the genera, much less the species, hitherto discovered in the caves of Europe generally, though doubtless they deserve far greater attention than they have yet received. One exception, however, must be made in the case of *Cygnus falconeri*, a gigantic Swan from the Zebug cavern in Malta (*Trans. Zool. Soc.* vi. plate 30). The caves of South America yielded to the laborious explorations of Lund no less than thirty-four species of Birds, of which the greater part are identical with those now existing in the same country; but some have become extinct, and of these the most notable are a large *Crax* and a large *Rhea*.

SUBFOSSIL BIRDS.

Kitchen-middens. The next ancient Birds' bones known to us in the northern hemisphere are probably those of the Danish kitchen-middens. These reveal the existence (very likely, the abundance) of two species, long since banished from the spots where their remains are found—the Capercally (*Tetrao urogallus*), and the Great Auk or Gare-fowl (*Alca impennis*). Just as the *Lagopus albus* in the south of France indicates a subarctic or subalpine country with its normal fauna and flora, so does the former of these shew the coexistence with it of pine-forests in Denmark, though on other evidence it is plain that such forests cannot have existed there for many centuries. The latter, of which more must be said hereafter, does not perhaps prove more than that the surrounding seas, though cold, were free from ice in summer time.

Lake-dwellings. The Birds' bones hitherto recovered from the ruins of the lake-dwellings in Switzerland are all of species which now occur more or less commonly in the same neighbourhoods, and are therefore of comparatively little interest.

English Fens. On the other hand, the Fens of East Anglia have yielded proofs of a form now extinct not only in England, but even in Northern Europe. This is the Pelican, of which two humeri, one from Norfolk and the other most likely from the Isle of Ely, are preserved in the museums of the University of Cambridge. Whether the species be identical with either of those which now inhabit some parts of Southern Europe is undetermined; but it was undoubtedly a true *Pelecanus*, and apparently only differed from *P. onocrotalus* in its somewhat larger size.

Madagascar. At an uncertain but (geologically speaking) recent epoch in Madagascar, there flourished huge birds of Struthious affinities. The first positive evidence of their former existence was made known in 1851 by M. Is. Geoffroy St.-Hilaire, who gave the name of *Æpyornis maximus* to the species which had laid an enormous egg, sent to Paris a short time before; and the discovery of some bones of corresponding magnitude soon after proved to all but the prejudiced the kinship of the producer of this wonderful specimen, which not unnaturally recalls the mythical Roc that figures so largely in Arabian tales. Three, if not four, well-marked species of this genus have now been characterized from remains found in the drifted sands of the southern part of that island.

New Zealand. Next we must turn to our antipodes. In New Zealand birds' bones of gigantic size seem to have been first heard of from native report by Mr W. Colenso in 1838, and next year Mr R. Taylor obtained "part of a fossil toe" (*Ann. Nat. Hist.* xiv. p. 82). In the same year, however, and before news of this discovery was published, Mr Rule placed in Professor Owen's hands the fragment of a bird's femur, which the latter exhibited and described at a meeting of the Zoological Society, 12th November 1839. Other examples soon came to England, and at a meeting of the same society, 24th January 1843, that learned anatomist applied the name of *Dinornis novæ-zealandiæ* to the newly-found monster (*Proc. Zool. Soc.* 1843, p. 8). A few months later he was able to pronounce that he had distinguished the remains of five species of the genus (*tom. cit.* p. 144); and the memoir subsequently published in the Society's *Transactions* proved to be the first of a series unrivalled in its kind and fortunately still in progress. Bones innumerable have since been obtained, together with portions of the skin, showing the scales of the tarsus and the feathers of the body, to some of which adhered the tendons and bits of dried muscle, stones from the crop, and eggs, a few of the last containing remains of the embryo. At least eleven good species seem to have been discovered; and these, according to one of the latest authorities, Dr Haast (*Addr. Phil. Inst. Canterb.* 5th March 1874, p. 6), may be grouped in two families—*Dinornithidæ* proper, having the back-toe obsolete, and comprising the restricted genus *Dinornis* (spp. 5) and *Mionornis* (spp. 2); and *Palapterygidæ*, possessing a hallux, and including the genera *Palapteryx* (spp. 2) and *Euryapteryx* (spp. 2). It used to be taken as proved that all these birds flourished within quite recent times, and sanguine naturalists have even hoped that explorations would shew that all of them were not extinct; but, though there is abundant evidence to prove that they were the contemporaries of man in New Zealand, Dr Haast most strongly urges that the race of man who hunted and fed upon the "Moa"—for such name was applied to its bones by the natives—lived long before the Maori settlement of the islands. Here there is no room for his arguments (*Trans. N. Zeal. Inst.*), and prudence will perhaps suggest a suspension of judgment on this point. In the same formation as those which hold the relics of these wonderful birds have been found, but far more seldom, remains of others not less interesting. First there is *Harpagornis*, a Bird-of-prey, of stature sufficient to have made the largest *Dinornis* its quarry. Then we have *Cnemiornis*, a gigantic Goose—possibly related to the genus *Cereopsis*, with *Aptornis* and *Notornis*—two Ralline forms,

the first allied to *Ocydromus*, and the last, which has survived to our own day, though most likely extirpated within the last fifteen years, much resembling *Porphyrio*.[1] In company with these fossil or sub-fossil remains are often associated bones of other forms, which now seem doomed to destruction but still exist. Finally must be mentioned *Dromæornis australis*, an extinct Struthious bird, which formerly inhabited Australia, and was allied to *Dromæus*, the well-known Emeu.

BIRDS RECENTLY EXTIRPATED.

Dodo. From the consideration of Fossil Birds we are naturally led to treat of those which have been extirpated in modern times, and are made known to us by evidence of various kinds, and more or less old. The most remarkable of these is the Dodo (*Didus ineptus*), which, on the discovery of Mauritius by the Portuguese under Mascaregnas in the beginning of the 16th century, was found to inhabit that island. Voyagers have vied with each other in describing or depicting its uncouth appearance, and its name has almost passed into a byword expressive of all that is effete. Clumsy, flightless, and defenceless, it soon succumbed, not so much to the human invaders of its realm as to the domestic beasts which accompanied them, and there gaining their liberty, unchecked by much of the wholesome discipline of nature, ran riot, to the utter destruction (as will be seen) of no inconsiderable portion of the Mauritian fauna. The latest known testimony of the Dodo's existence is furnished by the copy of a journal (now in the British Museum) kept by one Benjamin Harry, mate of the ship "Berkley Castle," which shews that it survived until July 1861. It had its life most likely sometime longer, but of this there is no evidence forthcoming. For a century and a half all that was known of it was derived from the quaint and sometimes questionable accounts of early voyagers; certain pictures, mostly by Dutch artists—for the bird was not unfrequently sent alive to Europe, and the traffic of the East Indies was then chiefly in the hands of the Netherlanders—which pictures, however grotesque, were doubtless for the most part faithful portraits; and a few scattered relics—a foot in the British Museum, a head and foot at Oxford, a perfect skull at Copenhagen, and a fragmentary one at Prague. Still these (or indeed the Danish specimen alone) were enough to enable Professor Reinhardt to determine the affinity of the lost bird to the Pigeons, an alliance not before surmised, but one which scarcely anybody now disputes. In 1866, however, Mr George Clark of Mauritius discovered in the peat of a pool (the Mare aux Songes) in that island an abundance of Dodos' bones (*Ibis*, 1866, p. 141); and these, when transmitted to Europe, informed naturalists as to nearly every part of its osseous structure, which was soon after described in detail by Professor Owen (*Trans. Zool. Soc.* vi. p. 49).

Solitaire of Réunion. But the Dodo is not the only member of its family that has vanished. The little island which has successively borne the name of Mascaregnas, England's Forest, Bourbon, and Réunion, and lies to the southward of Mauritius, had also an allied Bird, now dead and gone. Of this not a relic has been handled by any naturalist. The latest description of it, by Du Bois in 1674, is meagre in the extreme, and though two figures—one by Bontekoe (*circa* 1646), and another by Pierre Witthoos (*ob.* 1693) have been thought to represent it (*Trans. Zool. Soc.* vi. p. 373, plate 62), their identification is but conjectural. Yet the existence of such a bird is indubitable.

Solitaire of Rodriguez. Far to the eastward of these two sister islands lies a third—Rodriguez. Here there formerly lived another Didine bird, sufficiently distinct from the Dodo of Mauritius to form a genus of its own—*Pezophaps solitarius*, the

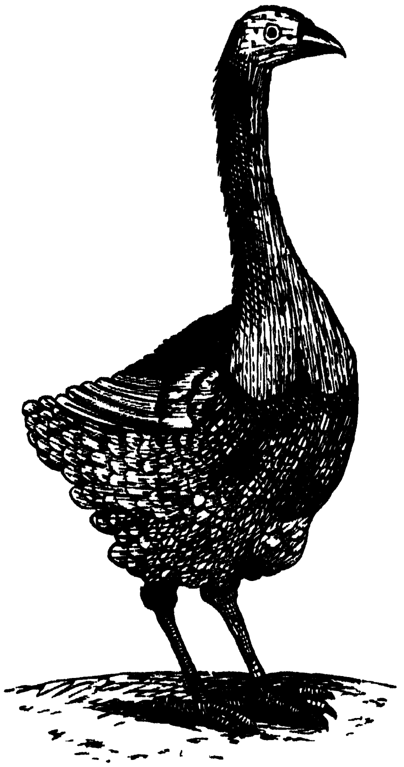

FIG. 43.—The Solitaire of Rodriguez (*Pezophaps solitarius*). From Leguat's figure

FIG. 44.—Extinct Crested Parrot of Mauritius (*Lophopsittacus mauritianus*). From a tracing by M. A. Milne-Edwards of the original drawing in a MS. Journal kept during Wolphart Harmanszoon's voyage to Mauritius (A.D. 1601–1602), *penes* H. Schlegel (*Proc. Zool. Soc.* 1875, p. 350). Reduced.

[1] A second species now referred to *Notornis* is the *Gallinula alba* of Latham, which lived on Lord Howe's (and probably Norfolk) Island. No specimen is known to have been brought to Europe for more than eighty years, and only one is believed to exist—namely, in the museum at Vienna (*Ibis*, 1873, p. 44, plate 10). Recent enquiries, made at the present writer's request, have failed to furnish any result. The bird is doubtless extinct. (*Cf.* Rowley, *Ornithological Miscellany*, pp. 38–48.)

Solitaire of Leguat, a Huguenot exile who, passing some time in 1691–93 on that island, has left, with a very inferior figure, a charmingly naive account of its appearance and habits, the general truth of which has been amply substantiated by Mr. Edward Newton's discovery in large numbers of its bones (*Phil. Trans.* 1869, p. 327); and a nearly complete skeleton of either sex may be seen in the museum of the University of Cambridge, by the side of the most perfect specimen existing of that of its bulkier relative, the Mauritian Dodo.

Other lost Mascarene Birds.

Nor does this group of Didine birds contain all the lost forms of the Mascarene islands. From Mauritius have

disappeared at least two species of Parrot, a Dove, a large Coot, and a second Ralline bird, abnormal, flightless, and long-billed—*Aphanapteryx*. A painting of this last was found by Von Frauenfeld in the emperor's library at Vienna, and some of its bones, rescued by Mr Edward Newton from the peat of the Mare aux Songes, have been fully described by M. A. Milne-Edwards. Remains of the Coot and one of the extinct Parrots were found also in the same spot, while skins of the other Parrot and of the Dove still exist in a few museums. Réunion, also, once had other birds now lost, and so had Rodriguez. In the former, a somewhat abnormal Starling (*Fregilupus*) existed until some forty years ago (*Proc. Zool. Soc.* 1874, p. 474), and its skin and skeleton are among the treasures of three or four museums. Perhaps, also, there were other Ralline birds, but the evidence on this head is inconclusive. In Rodriguez, the greater part of its original *avifauna* has vanished. There was a small but peculiar Owl (*Athene murivora*), a big Parrot (*Necropsittacus rodericanus*), a Dove (*Erythrœna?* sp. ign.), a large brevipennate Heron (*Ardea megacephala*), and a singular Rail (*Miserythrus leguati*)—in some respects allied to the Mauritian *Aphanapteryx*—besides other birds of which we know from old voyagers,[1] though their remains have not yet been determined (as those of the species above mentioned have been) from the numerous caverns of the island. A second Parrot, or rather Parrakeet (*Palæornis exsul*), still exists, but in very small numbers, and the unique specimen known was obtained in the year 1871.

Causes of extirpation.

With the examples of these Mascarene Islands before us, it is not without reason that we suppose a like fate to have befallen many of the feathered inhabitants of other places exposed to similar ravages. We cannot read the accounts not merely of the earliest voyages to the Antilles, but even of those performed within the last hundred years, without being aware that the writers met with many Birds which are not now known to inhabit them. These lost species, there is some ground for believing, were mainly, if not wholly, peculiar to the locality, and after having made good their existence, maybe, for ages, fell easy and helpless victims to the forces which European civilization brought into play. Chief among these forces was fire. In all countries and at all times it has been the habit of colonists to burn the woods surrounding their settlements—partly to clear the ground for future crops, and partly (in tropical climates especially) to promote the salubrity of their stations. When fire was set to the forest and bush of a small island, the whole of which could be burnt at once, the disastrous effect on its fauna can easily be conceived. Even the animals which happened to escape the conflagration itself would speedily starve, owing to the at least temporary destruction of the native flora whence, either directly or indirectly, they derived their wonted sustenance. Thus in certain of the Virgin Islands the "dead" shells of many species of terrestrial Gasteropods are everywhere found in astounding numbers, while not a living individual of several of the species has ever been met with by the conchologists.

[1] *Proc. Zool. Soc.* 1875, pp. 39–42.

of our day. The only assignable cause of the extinction of these creatures lies in the fact that these islands are known to have been laid waste by fire. The shells have resisted destruction, but how many more animals must have

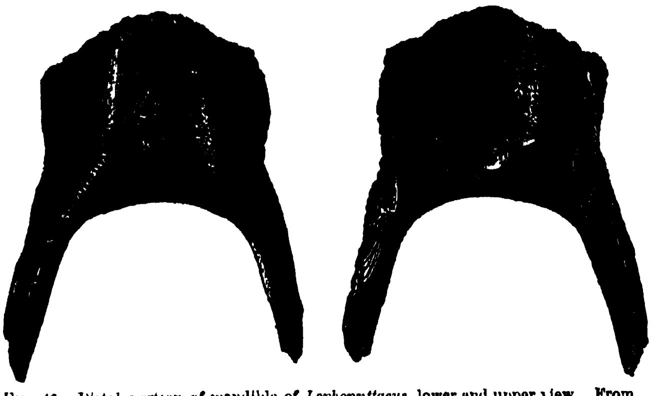

FIG. 46 – Distal portion of mandible of *Lophopsittacus*, lower and upper view. From specimen in the British Museum. These figures reproduced from *The Ibis*, 1866, by permission of the editor. Natural size.

perished without leaving a trace of their existence? Even at the present time, few parts of the world so overrun by people of European descent are from a naturalist's point of view so little known as the West-India Islands. Still

FIG. 47 —Extinct Starling of Réunion (*Fregilupus varius*), adapted from figures by Daubenton, Levaillant, and others. Reduced.

less is known of their state a century ago; and it would be a long and wearisome task to collect from old voyages the meagre, scattered, and often inaccurate information they contain as to the zoology of these islands. One example may, perhaps, be sufficient. Ledru accompanied an expedition sent out in 1796 by the French Government to the West Indies. In his work he gives a list of the birds he found in the islands of St Thomas and St Croix (*Voyage aux Isles de Teneriffe, &c.*, Paris, 1810, ii. p. 29). He enumerates *fourteen* kinds of birds as having occurred to him then. Of those there is now no trace of *eight* of the number; and, if he is to be believed, it must be supposed that within fifty or sixty years of his having been assured of their existence, they have become extinct.[1] And yet the period just mentioned was long subsequent to that in which the primeval woods of the islands were burnt. What, then, must not have been the changes which the forest-fires produced?

Lost Birds of Antilles.

If this be not enough we may cite the case of the French islands of Guadeloupe and Martinique, in which, according to M. Guyon (*Comptes Rendus*, lxiii. p. 589), there were once found *six* species of *Psittaci*, all now exterminated; and it may possibly be that the Maccaws stated by Mr Gosse (*B. Jamaica*, p. 260) and Mr Marsh (*Proc. Acad. N.S. Philad.* 1863, p. 283) to have formerly frequented certain parts of Jamaica, but not apparently noticed there for some twenty-five or thirty years, have fallen victims to colonization and its consequences.

Gare-fowl or Great Auk.

Mention has already been made of the Gare-fowl (*Alca impennis*), whose bones have been found in the kitchen-middens of Denmark, and more lately in similar deposits in Caithness. This species, nearly allied to our common Razor-bill (*A. torda*), but flightless and about twice as big, seems to have become extinct since 1844, in which year the last two examples known to have lived were taken on a rocky islet—one of a group called Fuglaskér, or Fowl-skerries, of the south-west point of Iceland. Ten years before, one had been caught alive at the entrance of Waterford harbour; and in 1821 or 1822 one was taken near St Kilda, to which lonely island, as appears from old authors, the bird had been accustomed to resort in the breeding season. In 1812 a pair were killed at Papa-Westray, which was also a breeding station of the species, and the stuffed skin of one of them is preserved in the British Museum, while that of the Waterford specimen may be seen in the museum of Trinity College, Dublin. In the Færoes the species was formerly common, but it certainly ceased from appearing there about the beginning of the present century. In the Iceland seas there are three localities called after the bird's name, but on only one of them has it been observed for many years, having probably been as long extirpated in the rest as in the Færoes. On the locality where it continued latest, there is ample evidence to show that it once was plentiful. There was a large skerry—the Geirfuglaskér proper—on which, in 1813, the crew of a Færoese vessel made a descent and slaughtered a large number of Gare-fowls; but this, like the rest of the group, was a place very difficult of access, and, in 1821, Faber, the well-known faunist of Iceland, failed to land upon it, though some of his companions reached the Geirfugladrángr, a smaller islet lying further to seaward. In 1830 the large skerry, through a submarine volcanic eruption, disappeared beneath the waves, and immediately after a colony of Gare-fowls was discovered on another rock lying nearer the mainland, and known as Eldey.[2] In the course of the next fourteen years, not fewer probably than sixty birds were killed on this newly-chosen station, and a nearly corresponding number of eggs were brought off; but the colony gradually dwindled until, as above said, in 1844 the last two were taken (*Ibis*, 1861, p. 374).

In Greenland, for the last three hundred years, the Gare-fowl has only been known as an occasional straggler, but it would appear that in 1574 a party of Icelanders found it so plentiful at a spot on the east coast—since identified

[1] One of the survivors (a Parrakeet, *Conurus xantholæmus*) was a few years ago restricted to a single hill-top in St Thomas, and so reduced in numbers that the present writer was ridiculed by many of the inhabitants for believing that such a bird ever existed in the island. Found, however, it was at last, but it must be regarded as verging upon extinction.

[2] Whether on the subsidence of the large skerry another portion of the birds which frequented it colonized the outermost islet is not known, for this spot does not seem to have been visited by any human being since Faber's time, more than fifty years ago.

with Danell's or Graah's Islands—that they loaded one of their boats with their captives. All recent explorations of this inhospitable coast prove the utter vanity of the notion that the Gare-fowl is able there to find an asylum.

But it was in the seas of Newfoundland that this species, known to the settlers and fishermen as the "Penguin,"—a corruption of the words "pin-wing,"—was most abundant, as a reference to Hakluyt's and similar collections of voyages will prove. In 1536, or forty years after the discovery of the country, we find an island taking its name from the bird, and others are even now so called. English and French mariners alike resorted to these spots, driving the helpless and hapless birds on sails or planks into a boat, "as many as shall lade her," and salting them for provision. The French crews, indeed, trusted so much to this supply of victual, as to take, it is said, but "small store of flesh with them." This practice, we learn from Cartwright (*Journal*, &c., iii. p. 55), was carried on even in 1785, and he then foresaw the speedy extirpation of the birds, which at that time had only one island left to breed upon. In 1819, Anspach reported their entire disappearance, but it is possible that some few yet lingered. On Funk Island, their last resort, rude enclosures of stones are, or recently were, still to be seen, in which the "Pin-wings" were impounded before slaughter; and a large quantity of their bones, and even natural mummies, preserved partly by the antiseptic property of the peat and partly by the icy subsoil, have been discovered. One of the last has furnished the chief materials from which the osteology of the species has been described (*Trans. Zool. Soc.* v. p. 317). Some 70 specimens of the bird's skin, about as many eggs, and nearly half-a-dozen more or less perfect skeletons, with detached bones of perhaps an hundred individuals, are preserved in collections; but even if there be any truth in the various reports of the appearance of the species since 1844 (some of which seem to rest on fairly good testimony), so that it may still survive, it is obvious that its rediscovery will most likely seal its fate.

Labrador Duck.

Far less commonly known, but apparently quite as certain, is the doom of a large Duck which even fifty years

FIG. 48.—Pied Duck (*Somateria labradora*), male and female. From specimens in the British Museum. Reduced.

ago was commonly found in summer about the mouth of the St Lawrence and the coast of Labrador, migrating in winter to the shores of Nova Scotia, New Brunswick, New England, and perhaps further southward. For many years past, according to the best-informed American ornithologists, not a single example has been met with in any of the markets of the United States, where formerly it was not at all uncommon at the proper season, and the last known to the writer to have lived was killed by Col. Wedderburn in Halifax harbour in the autumn of 1852.[1] This bird, the *Anas labradora* of the older ornithologists, was nearly allied to the Eiders (*Somateria*), and like them used to breed on rocky islets, where it was safe from the depredations of foxes and other carnivorous quadrupeds. This safety was however unavailing when man began yearly to visit its breeding-haunts, and, not content with plundering its nests, mercilessly to shoot the birds. Most of such islets are, of course, easily ransacked and depopulated. Having no asylum to turn to, for the shores of the mainland were infested by the four-footed enemies just mentioned, and (unlike some of its congeners) it had not a high northern range, its fate is easily understood. No estimate has yet been made of the number of specimens existing in museums, but it is believed to be not very great.

Phillip Island Parrot.

Another bird which has become extinct within the last few years is one of a group of Parrots (*Nestor*) peculiar to

FIG. 49.—Phillip-Island Parrot (*Nestor productus*). From specimen in the British Museum. Reduced.

the New-Zealand Subregion, and though some of its congeners still exist in the less-frequented and alpine parts of that country, this species (*N. productus*) seems to have been confined to Phillip Island. The last known to have lived, according to information supplied to the writer by Mr Gould, was seen by that gentleman in a cage in London about the year 1851. Not much more than a dozen specimens are believed to exist in collections.

BIRDS PARTIALLY EXTERMINATED.

From Birds which have recently become altogether extinct we naturally turn to those that have of late been extirpated in certain countries though still surviving elsewhere. Several such instances are furnished by the British Islands. First there is the Crane (*Grus communis*) which in Turner's time (1555) was described as breeding in our fens. Then the Spoonbill (*Platalea leucorodia*), said by Sir Thomas Browne

[1] It is needless to observe that no one at that time had any notion of its approaching extinction.

(1688) to breed in Suffolk, as it formerly had done in Norfolk. The Capercally (*Tetrao urogallus*) we know to have frequented the indigenous pine-forests of Ireland and Scotland. In the former it had most likely become extinct soon after 1760, and in the latter not much later. Not a single specimen of the British stock of this bird is known to exist in any museum, but the species has been successfully introduced from Sweden into Scotland during the last forty years, and is now certainly increasing in numbers. The Bustard (*Otis tarda*), which once tenanted the downs and open country of England from Dorset to the East Riding of Yorkshire, vanished from Norfolk, its last stronghold as a British Bird, in 1838. From other counties it had before disappeared. It is well worthy of note that all the four species just mentioned were protected to a certain degree by Acts of Parliament, but these laws only gave immunity to their eggs and none to the parent-birds during the breeding season, thus shewing how futile is the former when compared with the latter, since there are very many species whose nests from time out of mind have been and are yearly pillaged without any disastrous consequences arising from the practice.[1]

It would be impossible here to name the many Birds which, once numerous in the British Islands, have now so much diminished as to be rightly considered scarce, or to recount the various causes to which their diminution is due. The persecution of Birds-of-prey seems to have begun with the keepers of poultry, to whom the Kite (*Milvus ictinus*) and the Hen-Harrier (*Circus cyaneus*) were a sore trouble,[2] but it has been actively followed up by game-preservers, and this to their own cost, as the ravages of the Grouse-disease testify.[3] To the reclaiming of waste lands, the enclosure of open spaces, and the greater care bestowed on timber trees (by removing those that being decayed are much infested with insects) must, however, be attributed the extermination or rarification of far more species than the direct action of man has been able to effect.[4] Still what we lose in one direction we gain in another, and while Birds-of-prey and Wild-fowl are being banished, the smaller denizens of the woodlands, gardens, and arable fields are unquestionably more numerous than ever.[5] The change is, of course, not satisfactory to the naturalist or to the lover of wild scenery, but to some extent it seems inevitable; yet well directed laws for the protection of those birds which suffer worst in the unequal contest may delay their impending fate, and preserve to our posterity the most pleasing features of many a landscape and the grateful opportunities of studying many a curious and interesting species. Thanks, perhaps, to the stronger constitution of most Palæarctic Birds, the votaries of what is called "acclimatization" have obtained little success in these islands, for the exotic species which it has been attempting to introduce have, almost without exception, failed to establish themselves. The efforts made in some British colonies—particularly in Australasia—are unfortunately too likely not to be successful; and, when their own peculiar fauna has been half extirpated, our fellow-subjects at the antipodes will probably have good reason to lament the extraordinary sentiment that has led them to introduce from other countries birds which, in the absence of their natural checks, will be nothing else than a positive nuisance; for so reckless is the manner in which they have been imported, that species possessing few or exceedingly doubtful recommendations to begin with have been carried over in abundance, and some of these cannot fail to become permanent settlers equally with those for the transportation of which the would-be "acclimatizers" might find themselves excused. All, however, in the battle of life will contribute first to the subdual and by degrees to the disappearance of the original inhabitants, which had hitherto constituted a fauna, from a scientific point of view, perhaps the most interesting on the face of the globe.

GEOGRAPHICAL DISTRIBUTION OF BIRDS.

It is admitted by nearly all naturalists that the study of the extinct organisms of any country leads the investigator of them to a proper appreciation of its existing flora or fauna; while, on the other hand, a due consideration of the plants or animals which may predominate within its bounds cannot fail to throw more or less light on the changes it has in the course of ages undergone. That is to say that the Distribution of forms in Time is a subject so much connected with the Distribution of forms in Space, that the one can hardly be separated from the other. Granting this as a general truth, it must yet be acknowledged as a special fact, which some of the preceding paragraphs will perhaps have foreshadowed, that in fossil Ornithology we have as yet but scanty means of arriving at any precise results which will justify bold generalization in the matter of aviarian distribution. Remains of extinct forms of Birds are, compared with those of other classes of Vertebrates, exceedingly scarce, and in accordance, therefore, with the prevalent practice of naturalists they have been but little investigated. If we except France and New Zealand—and in the latter no fossil ornithic relics can be assigned to any very ancient epochs—little has been done. The discovery in the former of somewhat early remains of Birds, allied to those which we at present only know as denizens of a tropical region, and the recognition of far later remains of species identical with those that now flourish in arctic lands, merely corroborates what is from numerous sources within the knowledge of every geologist—the vicissitudes, namely, of which that part of Europe has had experience. Though in this quarter of the globe we now have no indigenous Struthious Birds, the former existence of Struthious Birds even in England proves very little, because we know that some of such birds (the species of South-American *Rhea*, for instance) can maintain themselves in lands which are subject to a climate as fitful, if not as severe, as our own. All that can be justly inferred thence is that Struthious Birds were not formerly confined to their present limits, and possibly that such birds once pervaded the greater part of the earth's surface. The *Archæopteryx* and *Odontopteryx* from their singularity prove nothing in respect of Geographical Distribution. Perhaps in the whole range of zoology there is no class from the fossil remains of which we learn less as regards the physical history of our planet than we do from the Birds. We, therefore, have to turn to the other side of the question of Distribution, and try to find out whether the

Scarcity of Ornithic fossils.

[1] The singular wisdom of the old command (Deut. xxii. 6)—the most ancient "game-law" (using the term in its widest sense) in existence—has here a curious exemplification.

[2] The Bohemian Schaschek, who visited England about 1461, says he had nowhere seen so many Kites as around London Bridge (*Bibl. Lit. Ver. Stuttgart*, vii. p. 40). And the statement is confirmed by Belon (*Obs. ad. fin. Clus. Exot.* p. 108), who says that they were scarcely more numerous in Cairo than in London, feeding on the garbage of the streets and even of the Thames. From the same writer (*Hist. Nat. Oyseaux*, p. 131) it would seem that at that time (1555) they, and Ravens also, were protected by law in the City! The Hen-Harrier's name is enough to shew what was thought of it in days when it abounded.

[3] In Transbaikalia, the Bearded Vulture (*Gypaetus barbatus*), which was formerly common, has of late been completely exterminated, through persecution prompted by the desire to obtain its feathers, which are highly valued.—Von Middendorff, *Sibir. Reise*, iv. p. 851.

[4] The extermination from Europe of the Francolin (*Francolinus vulgaris*) has been treated at some length by Lord Lilford (*Ibis*, 1862, p. 352) without his being able to assign any cause for the fact.

[5] *Report from the Select Committee on Wild Birds' Protection, &c.* (House of Commons), 1873. Appendix, pp. 188-193.

evidence, which is from one point of view so evidently deficient, may not be supplied by inquiry into existing *avifaunæ*, and this, in other words, signifies that a knowledge of the Geographical Distribution of living Birds becomes a matter of prime necessity to every one who would intelligently exercise the calling of an ornithologist.

Zoological Distribution determined from that of Birds.

Thus driven to a kind of extremity, the student of Birds, however, cannot but regard with the most lively satisfaction the circumstance that to one of his brethren is due the merit of having first truly pointed out the great Zoogeographical Regions of the globe—a fact not a little surprising when we reflect that the outlines of Distribution laid down in 1857 by Mr Sclater [1] had reference only to the most vagrant Class of animals in creation; yet these outlines have, not merely in the main, but to a very great extent in detail, met with the approval of nearly all those zoologists who have since studied the subject in its bearing upon the particular Classes in the knowledge of which they themselves stand pre-eminent.

General principles.

Without infringing upon what must be deemed the generalities of biological Distribution, it is proper to observe that Mr Sclater's success is to be attributed to the method in which his investigations were carried on—a method in which he had but few predecessors. Instead of looking at the earth's surface from the point of view which the geographer would take of it (a point of view which had hitherto been adopted by most writers), mapping out the world according to degrees of latitude and longitude, determining its respective portions of land and water entirely regardless of the products of either element, or adhering to its political divisions—time-honoured as they were,—he endeavoured to solve the question simply as a zoologist should, by taking up the branch of the subject with which he was best acquainted, and by pointing out and defining the several Regions of the globe in conformity with the various aspects of ornithic life which they present. But herein there was at once a grave difficulty to be encountered. Birds being of all animals most particularly adapted for extended and rapid locomotion, it became necessary for him to eliminate from his consideration those groups, be they large or small, which are of more or less universal occurrence,[2] and to ground his results on what was at that time commonly known as the order *Insessores* or *Passeres*, comprehending the orders now generally differentiated as *Passeres* (*veræ*), *Picariæ*, and *Psittaci*.

The six great Regions.

On this basis then Mr Sclater was enabled to set forth that the surface of the globe exhibited *six* great Regions, each in a marked manner differing from all the rest, though the difference was not always equally important. These Regions he termed respectively the Palæarctic, Ethiopian, Indian, Australian, Nearctic, and Neotropical; and though it is on all accounts better to preserve the names he bestowed on them, it does not seem convenient to follow the order in which he placed them. Thus the Australian Region appears not only to differ more from the others than they do among themselves, but its differences are of a kind which, when its fauna is considered as a whole, suggest a striking peculiarity, namely, that many of the forms of animal life therein found are the direct and not very much modified descendants of types which may very likely at an early period of our planet's history have predominated over every land, but of types which have since been elsewhere in great part replaced by more highly developed structures. The lower rank in the scale of its most characteristic animals seems to be indisputable, and, therefore, with the Australian Region it appears most proper to begin.[3]

Australian Region.

I. The Australian Region is most trenchantly divided from the Indian, which, from a geographical and possibly from a geological point of view, seems to be conterminous with it, by the narrow but deep channel which separates the small islands of Bali and Lombok, and will be found to determine the boundary between two entirely distinct portions of the earth's surface.

Boundaries.

Midway along this channel we may draw a line in our imagination, and continue it in a north-north-easterly direction up the Strait of Macassar, dividing the much larger islands of Celebes and Borneo. A considerable interchange of animal forms in the two islands last named is indeed to be observed, and even a slight intermingling of the productions of the two former seems now to be going on; but the inosculation is so much less in degree than that which obtains between any other two Regions, while the characteristic, not to say peculiar, zoological types which occupy either side of this line are so divergent, that it may be fairly considered a harder and faster line than any that can elsewhere be found.

Wallace's Line.

Between Bali and Lombok, as above stated, it has been shewn by Mr Wallace to be all but perfect, and in his honour this boundary, as real in the abstract as though it existed in the concrete, has been most justly named after the naturalist and traveller who first saw and recognized its importance—"Wallace's Line."[4] As above indicated, this line becomes less definitive as it proceeds further northward; and though we know it to pass between the Philippine Islands and Sanguir, and again between the former and the Palau group, its further progress in that direction cannot as yet be set down with precision, though it probably runs to the westward of the Ladrones. But hereabouts we lose sight of it, until we arrive at the Sandwich Islands, to the northward of which it must pass, since for reasons presently to be given at greater length that archipelago must be confined within the Australian Region. Southward from Lombok the boundary of the Region rounds the western coast of Australia, and then strikes off in a south-easterly direction to encompass New Zealand and its dependencies. Arrived here it must be drawn so as to include all of what is commonly known as Polynesia, though the characters of the intermittent chain of islets lying parallel to and just to the southward of the Tropic of Capricorn, and a few scattered reefs to the northward of the equator (between long. 108° and 115° W.), are at present insufficiently determined. After encircling, however, the Low Archipelago and the Marquesas, the boundary trends to the north-west, and includes, as before stated, the Sandwich Islands; but thence its precise direction cannot now be traced, owing to the obscurity which veils the numerous islets of the North Pacific Ocean, which

---

[1] *Journal of the Proceedings of the Linnean Society, Zoology*, ii. pp. 130-145. It is much to be regretted that the author of this most valuable essay has never sanctioned its republication in another and improved form. Many of its details, and some of its principles even, are now known to be incorrect, but for the time at which it appeared it was a marvellous production.

[2] Not but that even in the most widely-spread groups are contained others—sub-families, genera, or species strictly limited to certain localities. Some of these will be noticed further on.

[3] The writer has to acknowledge with hearty thanks the very singular mark of confidence conferred on him by his eminent friend Mr A. R. Wallace, who has allowed him to peruse in manuscript the greater part of a work on the Geographical Distribution of Animals, the early publication of which can hardly fail to place this most interesting subject in the position it undeniably deserves, but a position to which it has never yet attained through the absence of any treatise of like character. The value of the favour thus bestowed upon him the writer cannot overestimate.

[4] This name was first given by Professor Huxley (*Proc. Zool. Soc.* 1868, p. 313), but as it is hardly a geographical term, it will accordingly make no appearance on any save a so-called "physical" map. The value of the discovery above mentioned, of which no one had ever dreamt till it was made by Mr Wallace, seems to justify proper notice from chartographers, and it might be well, therefore, to dignify the channel between Bali and Lombok—named on some maps Lombok Strait—by the appellation of "Wallace's Strait."

lie between that group and the coast of Asia. All that can be said for certain is, that it does not comprise the Aleutian Islands, the empire of Japan, or the Loochoos.

General characteristics.

Though the characteristic Mammals of the Australian Region are in every way highly remarkable, entirely comprehending as they do one of the three Subclasses (*Ornithodelphia*) and nearly all of a second (*Didelphia*), by far the largest portion of the area it covers is weak if not absolutely wanting in Mammalian life, and the zoological features which mark the Region as a whole are perhaps better exhibited by its Birds than by any other Class of its fauna. This being the case, it may be excusable in this place to dwell longer upon this Region than upon the rest. True it is that we have no Subclass of birds, like the *Ornithodelphia* among Mammals, which is restricted to the Region; but, on the other hand, the instance of the *Didelphia*, to which allusion has just now been made, is here almost exactly paralleled by that of the Struthious Birds—the *Ratitæ*, to call them by the name now very generally applied to them by the zoologists who recognize them as forming one of the two primary divisions or Subclasses, we may term them, of the Class *Aves*. All the existing *Ratitæ* (with the exception of the species of two forms, the Ostriches of Africa and South America, belonging to the genera *Struthio* and *Rhea*, and comprising at most but five species) are found within the Australian Region and nowhere else. But further, the *Ratitæ* of the Region are more widely distributed throughout its area than are the *Didelphia*, since the former extend from Ceram, in lat. 4° S. and long. 130° E., to New Zealand in lat. 45° S. and long. 175° E., if not a little further, while the *Didelphia* stop short at lat. 44° S. and long. 155° E.[1] But if we take the birds alone, and compare the two Subclasses into which the existing or recent members of the Class are divided, we find the Australian Region remarkable for its ornithic singularity. The smaller of these two Subclasses, the *Ratitæ*, contains six very natural groups—which might well be called Orders—including, according to the most exaggerated computation of their number, less than 40 species, while the larger Subclass, the *Carinatæ*, though perhaps not including more truly natural groups, comprehends some 10,000 species. Now, out of the six groups of this smaller Subclass, four are absolutely restricted to the Australian Region, and these four groups contain all but, at the highest estimate, as above stated, five of the species known to belong to the Subclass; thus we should be able to regard the 35 species of recent *Ratitæ* of the Region (a number which is clearly far too large) as the proportional equivalent of an avifauna of more than 8000 species (8750).

Prevalence of *Ratitæ*.

Leaving, however, such a calculation as this, which indeed cannot as yet be more than an approximation to the truth, we must consider first the remaining ornithic features of the Region as a whole, and then those of its parts. With respect to each of those subjects, it will be evident to every one that a further division is at once incumbent upon us. The prevalent zoological features of any Region are of two kinds—negative and positive. It is therefore just as much the business of the zoogeographer, who wishes to arrive at the truth, to ascertain what groups of animals are wanting in any particular locality (altogether independently of its extent) as to determine those which are forthcoming there. Of course, in the former case it would be absurd to regard as a physical feature of any great value the absence from a district of groups which do not occur except in its immediate neighbourhood; but when we find that certain groups, though abounding in some part of the vicinity, either suddenly cease from appearing or appear only in very reduced numbers, and occasionally in abnormal forms, the fact obviously has an important bearing. Now, as has been above stated, mere geographical considerations, taken from the situation and configuration of the islands of the so-called Indian or Malay Archipelago, would indicate that they extended in an unbroken series from the shores of the Strait of Malacca to the southern coast of New Guinea, which confronts that of North Australia in Torres Strait, or even further to the eastward. Indeed, the very name Australasia, often applied to this part of the world, would induce the belief that all the countless islands, be they large or small—and some of them are among the largest on the globe—were but a southern prolongation of the mainland of Asia. But it has been already stated that so far from this being the case a very definite barrier is interposed. A strait, some 15 miles or so in width, and separating the two fertile but otherwise insignificant islands of Bali and Lombok, makes such a frontier as can hardly be shewn to exist elsewhere. The former of these two islands belongs to the Indian Region, the latter to the Australian, and between them there is absolutely no true transition—that is, no species are common to both which cannot be easily accounted for by the various accidents and migrations that in the course of time must have tended to mingle the productions of islands so close to one another. The faunas of the two are as absolutely distinct as those of South America and Africa, and it is only because they are separated by a narrow strait instead of the broad Atlantic that they have become so slightly connected by the interchange of a few species and genera.

A very definite boundar

Indian forms wanting here.

Now, first, of the forms of Birds which are prevalent throughout the Indian Region, but are entirely wanting in the Australian, we have at once the Bulbuls (*Ixidæ*), very characteristic of most parts of Africa and Asia, with the allied group of *Phyllornithidæ*, which is peculiar to the Indian Region; the widely-spread families of Barbets (*Megalæmidæ*) and Vultures (*Vulturidæ*); and the Pheasants (*Phasianidæ*), which attain so great a development in various parts of the Asiatic continent and islands that there must their home be regarded as fixed, though some species are found very far removed from the *focus* of the family.[2] Some naturalists would add the Finches (*Fringillidæ*), but the real position of the so-called "Finches" of Australia must at present be considered extremely doubtful, and it may prove that they are the direct descendants of the more generalized group whence sprang both the true *Fringillidæ* and the *Ploceidæ*, if, indeed, these can justifiably be kept apart. Then, of forms which are but weakly represented, we have the otherwise abundant Thrushes (*Turdidæ*[3]), and, above all, the Woodpeckers (*Picidæ*), of which some 4 species, or at most 5,[4] out of more than 300, just cross

[1] Of course, as regards polymorphism, no comparison can be made between the *Ratitæ* and the *Didelphia*, the latter presenting a very great variety and the former a very great sameness of structure and habit, though if it be true, as seems to be most likely the case, that *Dinornis* and its allies were absolutely devoid of wings, we should in them have a divergence from the normal ornithic type which is altogether unique in the whole Class, and for its singularity might well be set off against the multifariousness exhibited by the *Didelphia*.

[2] The separation of this family from the *Tetraonidæ* (Partridges and Grouse), though hitherto almost universally recognized, seems to be a very questionable proceeding, and, so far as the present writer is aware, is one that can only be maintained by structural characters, which though patent in their extreme forms, appear to vanish in those which are intermediate (*cf. Proc. Zool. Soc.* 1868, pp. 300, 301); but for the purposes of this treatise it is of little consequence, since the *Tetraonidæ* are but very feebly represented in the Australian Region.

[3] It is almost certain that no satisfactory limits can be laid down between this family and the Warblers (*Sylviidæ*), but, as is the case mentioned in the last note, the result would hardly be affected by combining the two families, since the *Sylviidæ* have comparatively few members in the Region now under notice.

[4] There are said to be *Dendrotypes analis* in Lombok, *Muelleripicus fulvus* and *Yungipicus temmincki* in Celebes, *Y. moluccensis* in the

the boundary and occur in Lombok, Celebes, or the Moluccas, but are absolutely unknown elsewhere in the Region.

Characteristic families. Turning to the families which by their presence characterize the Australian Region, we find those which are peculiar to it to be perhaps, if not more numerous, yet more remarkable than the peculiar families of any other Region. Nearly 20 such might here be enumerated. One, the Honeysuckers (*Meliphagidæ*[1]), is most characteristic, and, abounding in genera and species, extends to almost every part of the region, yet only a single species oversteps its limits, crossing the sea from Lombok to Bali.[2] Other peculiar families are much more confined, and, since by their means (as will presently appear) the various subdivisions of the Region may be more clearly marked out, further notice of them may be for the present deferred. But the positive characteristics of the Region as a whole are not its peculiar forms alone; there are at least 4 families which, being feebly represented elsewhere, here attain the maximum of development. Such are the Thickheaded Shrikes (*Pachycephalidæ*), the Caterpillareaters (*Campephagidæ*), the Flowerpeckers (*Dicæidæ*), and the Swallow-Flycatchers (*Artamidæ*). Besides these, 3 or perhaps 4 groups, though widely distributed throughout the world, arrive in the Australian Region at their culmination, presenting an abundance of most varied forms. These are the Weaver-birds (*Ploceidæ*, and the Moreporks (*Podargidæ*), if they can be properly separated from the *Fringillidæ* and the *Caprimulgidæ* respectively, but especially the Kingfishers (*Alcedinidæ*) and the Pigeons (*Columbidæ*), the species belonging to the two last obtaining in this Region a degree of prominence and beauty which is elsewhere unequalled.

Without going into greater detail, the Australian Region may be roughly said to be composed of *four* Subregions, to which the names of Papua (or New Guinea), Australia proper, New Zealand, and Polynesia may perhaps be attached. The boundaries of some of these Subregions are, as may be expected, not well defined; and, indeed, it is obvious that much must be done in the way of geographical exploration before the investigation of zoologists will mark out their limits with positive accuracy. Especially is this true in respect of the first of these Subregions, which in certain parts shows a complication of characters that for want of space could hardly here be explained, if indeed, according to our present information, they can be explained at all.

Papuan Subregion. (1.) *The Papuan Subregion*, the chief province of which is formed by New Guinea and its dependencies, comprises, besides the large and imperfectly-known island whence its name is derived, three other provinces, which may be named the Timorese, the Celebesian, and the Moluccan. **Timorese province.** The fauna of the Timor group seems to be made up of contributions from Java, belonging to the Indian region, the Moluccas, and Australia. Of nearly 100 genera and 160 species of Land-birds only, which are here found, an equal proportion appears to be related to the Birds of the Indian Region and to those of Australia proper—some 30 genera being distinctly traceable to each. The Indian influence is made evident by the presence of about 27 genera which have crossed the strait from Bali into Lombok. Of these, 12 are known to stop short at Flores, but the intervening island of Sumbawa has not yet been ornithologically explored, and 13 of them reach Timor. In all there may be, disregarding birds of wide distribution, some 30 species of Indian origin, with nearly 20 thereto allied, but, on the other hand, more than 60 which are derived from Australia, thus indicating a greater affinity to the latter country. There is one genus of Kingfishers (*Caridonax*) known only from Lombok and Flores, but no doubt represented in Sumbawa, and a genus of Pigeons (*Leucotreron*) is almost limited to this group.

Celebesian province. The Celebesian province is known to be inhabited by more than 200 species, belonging to about 150 genera. Of the Land-birds, 9 genera and nearly 70 species are absolutely confined to the principal island, but 20 more are found also in the Sula and Sanguir islands, making nearly 90 species peculiar to this Subregion. Of those which are not peculiar, Lord Walden[3] estimates that about 55 are of Indian and 22 of Australian origin, the remainder being common to both Regions, and thus the Indian influence is very strong in this quarter, pointing to an immigration from the north and west. Of the less wide genera of Celebes, more than 20 are common to Borneo and Java, and nearly as many to Timor or the Moluccas—again showing a preponderance of Indian over Australian types; but, since the Bornean and Javan species consist of only about one-quarter of those which are characteristic of those islands, while the Moluccan and Timorese genera form nearly one-half, the proportion which has been drawn from the rest of the Australian Region is clearly greater than that which has flowed in from the Indian. The most important family of *Meliphagidæ*, however, which, as before remarked, is so highly characteristic of the Australian Region, is here represented by a single species only (*Myzomela chloroptera*), and the fact requires due acknowledgment. On the other hand, some 8 Indian families which are very important in Borneo and Java are altogether absent, and the non-appearance of a still greater number of Moluccan forms is also worthy of note. The conclusion at which Mr. Wallace arrives from these and some other circumstances is that Celebes, during the existing epoch, has never been united by extensive land with either side, but has received an influx of immigrants from each. Of the genera found in Celebes itself 9 are peculiar, 3 more occur in one other island only, and 1 (which is likely to be eventually discovered in Celebes) is as yet known but in the Sula group. Of these 13 genera peculiar to the Subregion, about one-third are modifications of Australian forms. The Sula Islands show a considerable blending of faunas; out of nearly 40 species of Land-birds, more than one-half are identical with or allied to those of Celebes; but 3 Moluccan genera, unknown to Celebes, occur here.

Papuan province. We have now to consider the Papuan province. The island of New Guinea, which is the centre of the whole Papuan Subregion, has been until lately almost entirely unexplored, and even at the present day its interior has been but scarcely and cursorily visited by civilized foreigners. Yet out of nearly 350 species of Land-birds, belonging to 125 genera, which are known to us from this country, 300 species are exclusively peculiar to it, and 36 genera are either peculiar or only just extending to North Australia. Of the remaining genera, 38 are peculiar to the province, 45 are characteristically Australian, 9 more especially belong to the Malay Archipelago generally, being as much Australian as Indian. Only 7 are typically Indian, but with a discontinuous distribution, while 25 have a wide range. The chief features of the province to be noted are the extraordinary development therein of the Cassowaries

Moluccas, and *Y. otarius* there or perhaps in the Sunda Islands. It is quite likely, however, that further investigation will add to the number.

[1] This term is here advisedly used in a restricted sense, excluding the genus *Zosterops* and its allies, which are often included under it by systematists.

[2] This is *Ptilotis limbata*, a species which is common from Timor to Lombok.

[3] *Transactions of the Zoological Society*, viii. pp. 23-118.

(*Casuariidæ*),[1] the richness and specialization of the Kingfishers (*Alcedinidæ*), Parrots (*Psittaci*), and Pigeons (*Columbidæ*), its Birds-of-Paradise (*Paradiseidæ*), Honeysuckers (*Meliphagidæ*), and some remarkable Flycatchers (*Muscicapidæ*). It has several marked deficiencies compared with Australia, among which are the Warblers (*Sylviidæ*), Babblers (*Timeliidæ*), Finches or Weaver-birds (*Fringillidæ* or *Ploceidæ*)—according as we are disposed to treat those groups—certain Parrots (*Platycercinæ*), and Diurnal Birds-of-Prey (*Falconidæ*), and, above all, the Emeus (*Dromæidæ*). About 9 genera are especially Malayan, and nearly as many more have apparently the same origin, but, curiously enough, are not found in the intervening Moluccan province. Thus it will be seen that the avifauna of New Guinea is pre-eminently that of the Australian Region, and that it has many peculiar developments of Australian types; but that there has also been an infusion of Malayan forms, of which one group is spread pretty uniformly over the whole Archipelago, if not beyond it; while another group presents a rare instance of discontinuous distribution—not appearing in an intervening space of 1000 miles across, though that space is full of islands to all appearance habitable by such forms. The birds of Papua are, as a whole, remarkable for their brilliancy of plumage, one-half of the species occurring there being so distinguished, and no less than 12 genera are decorated by the metallic colouring of their feathers. The Birds-of-Paradise, the Racquet-tailed Kingfishers, the largest and smallest of the Parrot tribe, namely, *Calyptorhynchus* and *Nasiterna*, and the great Crowned Pigeons (*Goura*) are very characteristic among its productions.

The chief dependencies of New Guinea require some little notice. These are the Aru Islands in the west, and New Britain and New Ireland in the east, with the Solomon Islands as still more distant outliers in the same direction, and the Louisiade group in the south. The first, separated by 150 miles of sea from Papua, has over 100 species of Land-birds, of which, however, about four-fifths have been found also on the mainland; but among those which are peculiar are two of the finest *Paradiseidæ*—one of them belonging to a distinct genus (*Cicinnurus*)—and there is the very suggestive fact, as asserted, of two species of *Casuarius* occurring in the group. Of the ornithological features of New Britain and New Ireland not much is known, save that the former is inhabited by a species of Cassowary, and that both are intimately connected with New Guinea. The avifauna of the Solomon Islands is in some degree better understood, and 30[2] well-authenticated species of Land-birds, with 1 peculiar *Rallus*, have been found there. Of those 30, 16, or more than half, are known to be peculiar, while 3 more probably are so: 5 species occur in New Ireland as well; 1 is common also to New Caledonia and the New Hebrides, 1 to the Louisiade Archipelago, and the remaining 4 have a wider distribution in the Papuan Subregion, to which unquestionably the group belongs.

The Moluccan province, completing this Subregion and Moluc
consisting of many rather widely detached islands, which provin
lie for the most part between those forming the provinces already described, extends probably from Timor-leat in the south to the Sanguir group in the north, and includes the considerable islands of Ceram, Bouru, Gilolo, and Morty. About 200 species of Land-birds are now known from this province, and they may be assigned to over 80 genera. Of the species about 15 are common to the Indian region, but more than twice as many to the Papuan province, and some 140 are peculiar, of which the most significant are the *Casuarius* of Ceram.[3] Of the genera of Land-birds 2 only—*Semioptera*, a remarkable Bird-of-Paradise, and *Lycocorax*, an aberrant Crow—are peculiar; but there is also in Gilolo a brevipennate genus of Rails (*Habroptila*) to which the same epithet will apply. One genus is common to Ceram and Celebes, and another is found in Australia, whence possibly it is a migrant, while 30 genera are characteristic of the Papuan Subregion, and nearly 40 more, of more or less wide range, are found in and probably derived from New Guinea. Finally, there are some 12 genera which do not occur in New Guinea, and belong wholly or mainly to the Indian Region, but there are only 3 characteristically Indian types met with in the Moluccas, and all of them are there represented by distinct and well-marked species. The avifauna of the Moluccan province is therefore thoroughly that of the Papuan Subregion, and is no less clearly derivative from that of New Guinea, but not fewer than 11 forms of Birds-of-Paradise (*Paradiseidæ*), with more than 12 other characteristically Papuan genera, are wanting, and therefore, in Mr Wallace's opinion, it would seem as though the province is not a fragment of any old Papuan territory, a supposition supported by the fact that most Moluccan birds are very distinct from their representatives in New Guinea. Amongst the most characteristic forms are the scarlet Brush-tongued Parrots (*Lorius* and *Eos*), found, it is believed, in every island of the group, but not in the Celebesian or Timorese provinces. One species of *Eos* from Siau and Sanguir intimates that those islands belong to the province. *Eclectus*, another scarlet Parrot, but belonging to a different family, also is equally characteristic with the Parrots just mentioned. As a rule, the birds of the Moluccan province are larger and more conspicuous than the allied species from neighbouring parts.

On the whole, the avifauna of the Papuan Subregion Subreg
presents some very remarkable features, but most of them must be here briefly treated by way of summary. Unquestionably its most distinctive characteristic is to be found in the presence of the Birds-of-Paradise (*Paradiseidæ*), which are almost peculiar to it; for, granting that the Bower-birds (*Chlamydera* and others) of Australia should be classed in this family, it must be admitted that they are very abnormal, or perhaps, to take firmer ground, that they are far less highly specialized than the beautiful and extraordinary forms which are found, and found only within very restricted limits, in the various islands of the Subregion. It would be easy, if space allowed, to dwell at length on the many points of interest with respect to those wonderful birds, though in truth we know but little of them.

[1] The importance which must be attached to the distribution of Ratitæ as compared with Carinate birds, to say nothing of the interesting fact that the known number of species of *Casuarius* has been raised from one to nine in the course of a very few years, makes it advisable here to give a list of the 9 species, with the localities (so far as they have been ascertained) they inhabit, as announced to the Zoological Society of London, 16th February 1875, by Mr. Sclater, to whose courtesy the author owes the sight of a proof sheet of the communication:—

- *C. galeatus*, Ceram.
- *C. papuanus*, Northern New Guinea.
- *C. westermanni*, Jobie Island.
- *C. uniappendiculatus*, New Guinea.
- *C. picticollis*, Southern New Guinea.
- *C. beccarii*, Wokan, Aru Islands.
- *C. bicarunculatus*, Aru Islands.
- *C. australis*, North Australia.
- *C. bennetti*, New Britain.

A species of Cassowary has been said to occur in the Solomon Islands, and if so, one would think it likely to be distinct, but the only example alleged to have come from that group which has been examined proved to be *C. bennetti*.

It would seem not at all unreasonable that in dividing the Papuan Subregion into provinces we should be guided by the distribution of this remarkable genus. In that case, not only would Ceram be annexed to the Papuan province, but the Cape-York district severed from the Australian and added to the Papuan Subregion.

[2] As stated in the preceding note, a *Casuarius* is said to be found in the Solomon Islands, and, however contrary to expectation, would seem to be of the same species as that which inhabits New Britain.

[3] See preceding footnotes.

Australian Subregion.

(2.) *The Australian Subregion* is limited to the great insulated continent which bears that name, with its appendage Tasmania or Van Diemen's Land, and possesses, on the whole, a very homogeneous fauna—so much so, indeed, that at present it would be almost impossible to subdivide it into provinces. Influenced in the north by its proximity to the rich and varied Papuan Subregion,[1] its *ornis* rapidly becomes modified towards the south. Out of some 630 species or more, nearly 490 are Land-birds, and not more than one-twentieth of them are found elsewhere, so that its peculiar species bear a greater proportion to the rest than is the case in the Papuan Subregion. Though the western, and especially the north-western, parts of the country, which have been as yet but imperfectly investigated, will no doubt yield more results on further examination, it is already evident that the greatest animal wealth of Australia lies towards the east. The western portion seems to have but 2 peculiar genera (one of questionable value)—a nocturnal Parrakeet (*Geopsittacus*), and a Weaver-bird (*Emblema*), which is apparently not very far removed from others of the same group. In the north, as already stated, there is a considerable admixture of genera from the Papuan Subregion, which do not proceed beyond the tropic, and of these *Casuarius* is a striking example. The genus *Xerophila*, of uncertain affinity, is confined to South Australia; and the extreme limits of the Subregion, that is Tasmania, possess in addition only 1 genus, *Eudyptes*, belonging to the marine family of the Penguins (*Spheniscidæ*), which inhabit generally the sub-antarctic seas; but the Land-birds, which are few in number, are specifically identical with those of Australia proper. This is even the case with the Emeu (*Dromæus*), and the import of this fact is as significant [2] as would be a corresponding example drawn from the class *Mammalia*, since, in regard to means of locomotion, birds incapable of flight are on a par with terrestrial mammals. As a whole, Australia is rich in Parrots (*Psittaci*), having several very peculiar forms; but Picarians (*Picariæ*) of all sorts—certain Kingfishers (*Alcedinidæ*), perhaps, excepted—are few in number, and the Pigeons (*Columbidæ*) are also comparatively scarce. Australia, however, possesses two extraordinary families of abnormal *Passeres*—the Lyre-birds (*Menuridæ*) and the Scrub-birds (*Atrichiidæ*)—which, so far as is at present known, stand by themselves, though it is possible that the latter have a somewhat distant ally in the genus *Orthonyx*, or even in the South-American family *Pteroptochidæ*. The number of peculiar or characteristic genera of *Passeres* is, however, too great to be here enumerated; and there are many singular forms of *Columbidæ*. Among the more curious forms of Land-birds other than those may be especially remarked *Lipoa* among the *Gallinæ* (*Megapodiidæ*), and *Tribonyx* among the *Grallæ* (*Rallidæ*), while *Pedionomus* is a form referred by some systematists to the first and by others to the second of those Orders. The presence of a Bustard (*Eupodotis*) presents a curious example of interrupted distribution, since none of that family (*Otididæ*) are found nearer than India.

Polynesian Subregion.

(3.) *The Polynesian Subregion*, though so vast, extending as it does from one tropic to the other throughout ninety degrees of longitude (from long. 140° E. to long. 130° W.), at that part of the earth's surface where degrees of longitude are broadest, possesses generally a very uniform avifauna. It may possibly be partitioned into four or five provinces; but if so, the products of the first of them, containing the Palau [3] (commonly called Pelew), the Caroline, and most likely the Ladrone Islands, are at present too imperfectly known for any useful results to be drawn from them. Then we have the New Hebrides and New Caledonia forming another province; after which comes the third, or Central-Polynesian province, comprising the Fijian, Tongan, and Samoan groups; next the numerous clusters from Cook's Islands to the Marquesas, including the Society Islands and the whole of the Low Archipelago, which may perhaps form a fourth province; and lastly, the Sandwich or Hawaiian Islands. The first of these provinces (so to call them) possesses in the Palau Islands a Reed-Warbler, which seems to form a peculiar genus (*Psamathia*), while another kindred form belongs to the widely-spread genus (*Acrocephalus*) that our own English bird does, and occurs there, and there alone, so far as we know, throughout the whole Subregion.[4] The like may be said of a Goatsucker (*Caprimulgus*). 1 other typically Polynesian genus is found; 1 is common to the Papuan, and 1 to the Malayan (Indian) Subregion. The second province shows some transition from the Papuan to the Australian Subregion. Out of 30 genera of Land-birds, 18 are typically Australian, 13 are also Polynesian: about 5 go no further to the eastward. 3 species of *Aplonis*, a genus of uncertain affinity, but generally classed with the Starlings (*Sturnidæ*), seem to link this province to the Central-Polynesian, and a very remarkable and apparently very generalized form of *Grallæ*—the Kagu (*Rhinochetus*), which seems to have half-a-dozen scattered alliances—is peculiar to New Caledonia. From the third province only some 50 genera and some 150 species of Land-birds are known. A species of Cuckow (*Eudynamis taitensis*) ranges over the whole of this as well as the next district so far as the Marquesas, as also does perhaps an abnormal Warbler (*Tatare*). On the other hand, the Samoan group has in the Manu-mea or Tooth-billed Pigeon (*Didunculus*) a form which alone makes a distinct family of *Columbæ*; [5] and another island of the same group, Savai, produces a most peculiar brevipennate Water-hen (*Pareudiastes*), which it deemed worthy of generic separation from *Gallinulas*. The fourth province, which (if it may be recognized as such) may be called the Eastern-Polynesian, comprehends, as above stated, the countless islands which surround the Low Archipelago. Respecting these we have little precise information—two meagre lists of birds from Huaheine, one of the Society group, and a catalogue obviously not complete of those of the Marquesas, appearing to furnish nearly all our available material. The latter group possesses a rather remarkable Pigeon, said to be peculiar to it, but perhaps also found in the former; and though closely allied to *Carpophaga*, it has been elevated to generic rank under the name of *Serresius*. The last province is that of the Sandwich Islands, which, notwithstanding that their ornithology has never been thoroughly worked out, seem to present some conspicuous differences from any other; and it is almost a matter of opinion whether, small as is the known avifauna of the group, it should not be regarded as constituting a separate Subregion rather than as a province of Polynesia. The ascertained Land-birds are but 18 in number. Of these 3 are Birds-of-prey, and 1 of them, the *Pandion* (?) *solitarius* of Cassin, is only known in collections by a unique specimen. The other 2 are widely-distributed

---

1 The Peninsula of Cape York possesses a *Casuarius*, as already noticed, and other grounds are not wanting for the supposition that has been entertained that zoologically it belongs to the Papuan Subregion.

2 Its significance is increased by the fact that the Emeu of West Australia is distinct from that of the east. The Emeu is extinct in Tasmania.

3 Dr Finsch is understood to be especially engaged on the birds of this group of islands, to our knowledge of which he and Dr Hartlaub have already contributed much.

4 It is, however, found in Australia, and even in the south of that country.

5 It is possible, however, that *Otidiphaps*, which is supposed to come from New Guinea, may also belong to the *Didunculidæ*.

species of Owls (*Strigidæ*). There are no *Psittaci* or *Picariæ*. The *Passeres* consist of 15 well-established species, all peculiar to the group, and belong to 10 generic forms, only 1 of which, the cosmopolitan *Corvus*, is known to occur elsewhere. The remainder are restricted to the Hawaiian Islands and may be referred to 2 families—one the almost universally distributed Flycatchers (*Muscicapidæ*), and the other the Honeysuckers (*Meliphagidæ*), which, as has been said before, are preeminently characteristic of the whole Australian Region; but it is to be observed that the most of the species are remarkable for the extraordinary form of their bill, so that they may ultimately be found to constitute a special section of the family, if they be not considered to form a distinct one (*Drepanidæ*). There are also two peculiar species of Water-birds—a Coot (*Fulica alai*), and the well-known Sandwich Island Goose (*Bernicla sandvicensis*), which has been very commonly domesticated in Europe. The Hawaiian Archipelago has thus a larger proportion of peculiar genera and species than any other group in the Subregion, from which fact Mr. Wallace infers, and no one can doubt the truth of the observation, the great antiquity of its isolation.

New Zealand Subregion.

(4.) *The New-Zealand Subregion*, however, is, and to all appearance long has been, more isolated still, probably, indeed, longer isolated than any other portion of the globe. Beside the three larger islands, known in the aggregate as New Zealand, numerous satellites belong to the Subregion, as Lord Howe's, Norfolk, and Kermadoc Islands, with the Chatham, Auckland, and Macquarrie groups. At the highest estimate the Subregion contains about 150 existing species of birds, of which more than 60 are Land-birds, belonging to about 34 genera, 16 of the latter being peculiar, and there may be some 5 genera of Water-birds, making 21 in all. Of the others 4 are widely spread, but the rest (9 in number) are characteristically those of the Region. Most of the genera occurring elsewhere are here represented by peculiar species, but then 5 are common to Australia. Some 7 or 8 are also allied to Australian species, and there are 4 Australian and 1 Polynesian species. Therefore every degree of similarity to Australia is to be found. Of peculiar genera it will suffice to say that 2 (*Myiomoira* and *Miro*) belong to the Warblers (*Sylviidæ*), 1 genus (*Turnagra*) perhaps comes under the Babblers (*Timeliidæ*), and 2 genera (*Xenicus* and *Acanthositta*) may be referred to the Creepers (*Certhiidæ*). The *Paridæ* have 1 genus (*Certhiiparus*), and the *Meliphagidæ* 3 genera (*Prosthemadura*, *Pogonornis*, and *Anthornis*). The Starlings (*Sturnidæ*) are represented by *Callæas*, *Creadion*, and the very abnormal—or perhaps it would be better to say generalized—*Heterolocha*. An entire and very distinct family (*Strigopidæ*) of Parrots is certainly peculiar, and it may probably be justifiable to regard the genus *Nestor* as constituting a second. There is also an Owl, which has been usually considered the type of a genus (*Sceloglaux*); and the *Rallidæ* present two very remarkable forms—the Wood-hens (*Ocydromus*) and the Takahe (*Notornis*), the last almost, if not quite, extinct. The widely-spread family of Plovers (*Charadriidæ*) have two not less singular generic developments—*Thinornis* and the extraordinary Wrybill, *Anarhynchus*. Among the Ducks (*Anatidæ*), *Hymenolæmus* is a very curious form; and, finally, among the *Ratitæ* we have the whole family of weird-looking Kiwis (*Apterygidæ*), represented by three or four species, which are totally unlike any other existing birds. In all, there is a wonderful amount of specialization, though perhaps in a very straight line from generalized forms; but the affinity to Australian or Polynesian types is in many cases clearly traceable, and it cannot be supposed but that these last are of cognate origin with those of New Zealand. A very long period of isolation must have been required to produce the differences so manifestly to be observed, but a few forms seem at rare intervals to have immigrated, and this immigration would appear to be kept up to our own day, as shewn by the instance of *Zosterops lateralis*, which is said to have lately made its first appearance, and to have established itself in the country, as well as by the fact of two Cuckows, the widely-ranging *Eudynamis taitensis* and *Chrysococcyx lucidus*, which are annual visitors.

The most extraordinary ornithic feature of New Zealand, however, is unquestionably the former existence of the gigantic birds of the families *Dinornithidæ* and *Palapterygidæ*, with a few other contemporary forms. These, however, having been already mentioned there is no need to dwell further upon them. As a whole, the avifauna of New Zealand must be regarded as one of the most interesting and instructive in the world, and the inevitable doom which is awaiting its surviving members cannot but excite a lively regret in the minds of all ornithologists. This regret is quite apart from any question of sentiment; if it were otherwise, it could not be defended against that sentiment which prompts our colonial fellow-subjects indiscriminately to stock their fields and forests, not only with the species of their mother-country, but with all the fowls of heaven, whencesoever they can be procured. The regret we express arises from the thought that just as we lament our ignorance of the species which in various lands have been extirpated by our forefathers, so our posterity will want to know much more of the present ornis of New Zealand than we can possibly record; for no one nowadays can pretend to predict the scope of investigation which will be required, and required in vain, by naturalists in that future when New Zealand may be one of the great nations of the earth.

Doom of New Z land a fauna.

II. The Neotropical Region, though presenting certain affinities to the Australian, and the only one which can be said to be zoologically allied to it, is yet almost as distinct in its character therefrom as it is geographically distant. Excepting towards its northern limits, where it meets and inosculates with the Nearctic Region, the boundary of the Neotropical Region is simple enough to trace, comprehending as it does the whole of South America from Cape Horn to the Isthmus of Panama and all Central America, and reaching in North America to somewhere about the twenty-second parallel of north latitude; besides including the Falkland Islands to the south-east,[1] and the Galapagos under the equator to the west, as well as the whole of the Antilles or West-India Islands up to the Florida Channel, which separates them from the peninsula of that name. Though over none but the remotest corners of this sufficiently large area is the supreme Class of animals formed (as we have found it to be the case throughout by far the greater portion of the Australian Region) by the Birds, yet they here play a part of very great importance, owing to the comparatively scanty number of Mammalian types. Among these last, however, there are two remarkable groups—the *Pedimana*, containing the only members of the Subclass *Didelphia* which occur at the present day

Neotropic Regio

Boundaries.

Impor ance o Birds

[1] It may even be questionable whether Tristan da Cunha, though lying nearer to the African coast, should not be referred to the Neotropical rather than to the Ethiopian Region. On this lone spot but four species of Land-birds are known to occur, all of which are peculiar—two of them even generically. One is a Finch (*Crithagra insularis*), belonging, it is true, to a genus very well represented in Africa; but the second (*Nesospiza acunha*) is the type and sole member of a genus which, whether it be considered a Finch or a Bunting, is said by Dr Cabanis, its describer, to have unquestionable similarity to some South American forms (*Journ. für Orn.* 1873, p. 154). The third bird is a Thrush (*Nesocichla eremita*), like the last, peculiar both in species and genus to the island, and apparently having no relation to anything Ethiopian; while the fourth is a peculiar species of brevipennate Water-hen (*Gallinula nesiotis*), which may have been derived from either continent.

out of the Australian Region, and the *Edentata*, an Order which, though found also in Africa and India, attains in South America the summit of its development in variety and number of forms; and we cannot adduce any examples of Orders or Suborders from the Class *Aves*, the circumstances of which will exactly match those of these three groups of *Mammalia*. The nearest approach, perhaps, is made in one way by the South-American Ratite birds, of which one entire group, consisting of at most three species (*Rheidæ*), is peculiar to the region, and thus to some extent parallels the case of the *Pedimana*; but while these last also invade the Nearctic Region, the former are not even spread over the whole of continental South America, being limited to its colder portion. Moreover, so far as Orders have been generally understood and accepted by ornithologists among Carinate Birds, there is no one of wide range which can compare with the overwhelming development of the Edentates in the Neotropical Region. On the other hand, it must be observed that the Region claims all the Tinamous (*Tinamidæ*)—the *Dromæognathæ* of Professor Huxley—which, if we were to follow his arrangement established on palatal characters, it would seem necessary to regard as the equivalent of an Order; and also a single very remarkable form (*Opisthocomus*), which he has satisfactorily shown to be so unlike every other that it can only be conveniently classed by itself.[1] Of these forms the *Tinamidæ* certainly, and *Opisthocomus* probably, are of comparatively low developmental rank, in that respect resembling certain characteristic Australian groups; but the similarity between the avifaunas of the two Regions seems to be further borne out by the same fact being observable of other South-American families, forming what may be called the lower Suborders[2] of *Passeres*, to which the names of *Oligomyodæ* and *Tracheophonæ* have been attached, and these, if not altogether originating in the Neotropical Region, are without doubt therein most abundantly produced. The significance of this fact is enhanced when we remember that, as has been said before, to consider rightly the problem of the distribution of birds, we must in the main rely on the *Passeres*, as affording on the whole the surest ground for our investigations. Now, taking the latest, nay, the only, complete list of Neotropical birds—that published by Messrs Sclater and Salvin[3] in 1873, we shall see that there are 8 Passerine families peculiar to the Region, of which 3 belong to the *Tracheophonæ*, 4 to the *Oligomyodæ*, and 1 only to the *Polymyodæ* or *Oscines*. Or, if we look to the entire number of species given in that work as inhabiting the Region, we find it to be 3565. Of these, 1997, or a good deal more than half, belong to the Order *Passeres*—a large proportion truly, but one that (from other causes not germane to our present investigation, and therefore to be just now disregarded) need not especially excite our wonder. But the characteristic nature of the avifauna of the Region is more clearly brought out when we learn that of the 1997 species just mentioned, 1070 only belong to the higher Suborder (*Polymyodæ*); leaving 927 to the two lower Suborders (*Oligomyodæ* and *Tracheophonæ*), or to speak in round numbers, out of 2000 species of the highest Order of birds, a *little more than one-half* belong to its highest section, while *nearly one-half* belong to its two lower sections. This is a state of things which exists nowhere else on the globe; for, except in Australia, where a few but uncertain number of purely indigenous and peculiar non-polymyodous *Passeres* are found, and in the Nearctic Region whither one family of *Oligomyodæ* has evidently been led by the geographical continuity of its soil with that of the Neotropical Region, such forms do not occur elsewhere. Accordingly their disproportionate prevalence in South America and its neighbouring lands points unerringly to the lower rank of the ornis of the region as a whole, and therefore to the propriety of taking it next in order to that of the Australian Region, the general fauna of which is admittedly the lowest in the world. It is believed that much the same result would follow from a similar examination of other Orders, especially the *Picariæ*; and Professor Huxley has urged with his wonted perspicuity the alliance of the two Regions just named, basing his opinion in great measure on the evidence afforded by the two sections into which the true *Gallinæ* are divisible, the *Peristeropodes* and the *Alectoropodes*, the former composed of the families *Megapodiidæ*, almost wholly Australian, and the *Cracidæ*, entirely Neotropical, but citing also other weighty evidence in favour of his conclusion.[4]

General characteristics of its ornis.

Ornithic development comparatively low.

Leaving, however, this matter as in some degree hypothetical, though its probability can hardly be denied, we have as genera, families, or perhaps even larger groups a great many very remarkable forms which are characteristic of or peculiar to the Neotropical Region in part, if not as a whole. Of families we find 23, or maybe more, absolutely restricted thereto, besides at least 8 which, being peculiar to the New World, extend their range into the Nearctic Region, but are there so feebly developed that their origin may be safely ascribed to the southern portion of America. First in point of importance comes the extraordinarily beautiful family of Humming-birds (*Trochilidæ*), with nearly 120 genera (of which only 5 occur in the Nearctic Region), and more than 400 species. Then the Tyrants (*Tyrannidæ*), with more than 70 genera (8 of which range into the northern Region), and over 300 species. To these follow the Tanagers (*Tanagridæ*), with upwards of 40 genera (only 1 of which crosses the border), and about 300 species; the Piculules (*Dendrocolaptidæ*), with as many genera, and over 200 species; the Ant-Thrushes (*Formicariidæ*), with more than 30 genera, and nearly 200 species; together with other groups which, if not so large as those just named, are yet just as well defined, and possibly more significant, namely, the Tapaculos (*Pteroptochidæ*), the Toucans (*Rhamphastidæ*), the Jacamars (*Galbulidæ*), the Motmots (*Momotidæ*), the Todies (*Todidæ*), the Trumpeters (*Psophiidæ*), and the Screamers (*Palamedeidæ*); besides such isolated forms as the Seriema (*Cariama*) and the Sun-Bittern (*Eurypyga*).

Characteristic families.

Having thus briefly indicated some of the chief characteristic and for the most part generally distributed forms of the Neotropical avifauna, we have next to consider the separation of the Region into Subregions and provinces. Herein we find far greater difficulty than we had to encounter in treating of the preceding (the Australian) Region, the geographical peculiarities of which marvellously lend themselves to its comparatively easy partition, while the isolation of its several portions contributes in an extraor-

Division into Subregions.

[1] To recognize these Orders, *Crypturi* and *Opisthocomi*, however, it becomes logically necessary to recognize many other groups in like manner, and thus to raise the number of Orders in the whole Class to at least two dozen, or nearly four times as many as most ornithologists have been usually willing to admit, a proceeding which naturally lowers the differential standard, and renders a comparison between "Orders" of *Aves* and "Orders" of *Mammalia* or *Reptilia* almost impossible.

[2] The term "Suborder" should very possibly not be used here, at least in a technical sense. The *Passeres* seem to be properly divisible into two great groups—one containing the genus *Menura*, the other all the rest, except most likely *Atrichia*, which there is some reason to suppose may be found to form a third group. Whenever these groups shall receive names, they ought to be regarded as Suborders, but in the meantime, with this explanation, perhaps no harm will follow from calling the sections *Polymyodæ* (the *Oscines* of some writers), *Oligomyodæ*, and *Tracheophonæ* "Suborders."

dinary degree to the process. But compared with the remaining Regions of the globe, the Neotropical, as it will be essayed to show in the sequel, presents, perhaps, no greater difficulty in this respect than others do. The Subregions (one excepted), however, cannot be said to be well defined, for no natural boundaries are to be found for them, and we must trust solely to the presence or absence of certain forms of Bird-life in marking out their limits. This is, of course, the most proper zoological method of proceeding, but in some cases it tends to make the divisions rather more than less arbitrary, and in all cases dependent upon the amount of investigation which has been bestowed on the several districts. The physical features of the continent of South America are very varied, and cannot be said to assist us much or at all in our task. The proximity of its southern extremity to an ocean wherein at one season of the year floating ice abounds, gives that portion a rigorous climate, and the presence of the grand chain of the Andes, the highest save one in the world, prolongs beyond the equator those characteristics of a mountainous or even an alpine tract, which override any that are commonly associated with degrees of latitude. This range, the great Cordillera, has also a remarkable effect first on the climatological properties of the whole country, and then on its vegetation, which, of course, acts directly on its animal inhabitants. Running as the Andes do pretty nearly longitudinally, and lying near the western coast of the continent, the warm, moist winds from the Atlantic sweep across its eastern and wider portion, unimpeded in their course by any considerable high land, till they are attracted by the summits of the giant range, and, precipitating their fertilizing showers on its lofty slopes, supply the brimming floods of some of the largest rivers of the world. Westward of the chain is in great part a desert, at least down to lat. 10° S., though much of this was, prior to the conquest of Peru by the Spaniards, carefully irrigated and highly luxuriant. A few other arid tracts are found, but compared with most other continents the proportion of desert-land is small, and the valleys of the majestic rivers which roll their course to the Atlantic are clothed with the most extensive virgin forests in the world. To these varied physical conditions seem due the chief differences which are observable in the avifauna of the component parts of the South-American continent, which, rich as it is beyond that of all other countries in genera and species, displays yet a considerable uniformity in its larger groups of Birds.

Physical features of S. America.

Limits of the six Subregions.

The Subregions into which that portion of the earth at present under consideration can be most conveniently separated seem to be *six* in number—four of them included within the continent of South America, and two lying beyond its limits.[1] But the confines of these continental Subregions, as has been above hinted, are of the vaguest. It is doubtful whether any amount of local knowledge will ever justify the zoogeographer in drawing an absolute line of demarcation between any two of them. At present our information certainly does not permit us to do more than indicate the general direction of such boundaries; not that we believe that their existence may not be legitimately assumed. Beginning with the apex of the continent, we have a Subregion, extending from Cape Horn to somewhere north of Bahia Blanca on its eastern coast, whence its boundary runs in a north-westerly direction, passing to the eastward of Mendoza, and then northward along the eastern and higher slopes of the Andes until it crosses the equator, and, after trifurcating on either side of the valleys of the Magdalena and its confluent the Cauca, returns along the western slopes of the lofty Cordillera, until it trends seaward and reaches the Pacific coast of South America somewhere about Truxillo, in lat. 7° S. This Subregion, for a reason presently to be given, may be called the Patagonian, though its northern extremity lies so far removed from its eponymic territory. Next we have what may be called the Brazilian Subregion, marching with the foregoing until somewhere near Potosi in Bolivia, whence it turns to the north-east, and, avoiding the watershed of the Amazons, strikes, perhaps, the Paranahyba, through or along which it makes its way to the Atlantic. Then comes the enormous basin of the Amazons—the Mediterranean of South America, as the dwellers on its banks fondly call it—which, though forming an important part of the Brazilian Empire, seems undoubtedly to be a distinct Subregion from that to which this last name has been applied, and may justly be denominated the Amazonian. Yet, be it remembered, that, its peculiarities not being observable on the higher tributaries of the mighty river, its upper waters must be regarded as draining land which belongs to the fourth Subregion—of which more immediately. Continuous to the southward with the Brazilian boundary the western frontier of the Amazonian Subregion seems to turn off before the eastern confines of the Patagonian Subregion are reached, and, leaving a space intervening, it pursues a generally northward course, at a lower level, on the western bank of the Huallaga, and crossing the great stream whence it derives its name, in somewhere about long. 77° W. and lat. 5° S., it pursues its way towards the mouth of the Orinoco. The fourth and last Subregion of South America includes all that is left of the continent, and perhaps may be most fitly named the Subandean.[2] This begins in the south with the narrow slip of land before mentioned as intervening between the comparatively low-lying Amazonian Subregion and that portion of the Patagonian which runs along the lofty Peruvian Andes, and is believed to extend from the frontiers of Bolivia to the table-land of Ecuador, rounding, on the one hand, the forked extremity of the Patagonian Subregion to the westward until it meets the Pacific at Truxillo, stretching over 500 miles of sea to the Galapagos Islands, under the equator, and, on the other hand, following the Amazonian boundary to the Atlantic, while it comprehends the islands of Trinidad and Tobago, as well as those which lie on the northern coast of South America. Besides portions of the states already named, it includes Nueva Granada and Venezuela till it reaches the Central-American Subregion in the Isthmus of Panama. This fifth Subregion stretches on the west northward about as far as Guaymas on the east coast of the Gulf of California, and on the east to the Rio Grande, which forms the boundary of Mexico and Texas, but the Nearctic Region dips down along the central table-land till near Queretaro, a little to the northward of the city of Mexico, and thence southward along the higher ridges to an almost indefinite extent. The sixth Subregion is composed of the Antilles, with the important exception of Trinidad and Tobago, and its limits being capable of easy geographical circumscription, further consideration of them may be for the present deferred.

The difficulty of distinguishing these several Subregions is indeed very great; and it is not only possible, but highly probable that even in a few years further exploration will enjoin a large amount of rectification of their frontiers. It

[1] In arriving at this conclusion the author wishes to acknowledge the kind assistance he has received from his old friend Mr Salvin, F.R.S., whose long-continued study of American, and especially Neotropical, forms of birds has placed him in the front rank of authorities on the ornithology of the New World.

[2] In some respects it corresponds with what has been commonly called the "Columbian" Subregion; but that name, having been used in a special and more restricted sense, might give rise to some misunderstanding. As will be seen, it comprehends far more than the former United States of Columbia.

must be remembered too that where, in the preceding paragraphs, "lines" of demarcation have been spoken of, such lines are in truth tracts of country often from one to two hundred miles in breadth, and in most cases there is no hope that the boundaries will ever attain any great degree of precision. Some advance of knowledge in this direction will no doubt accrue as the elevation and contour of hills and table-lands become more accurately laid down; but at first the effect of this increase to our information will certainly be to complicate matters, by shewing the existence within one Subregion of spurs, isolated spots, or enclosed areas belonging to another, and as yet unsuspected. Still the amount of light thrown on the Neotropical Region by the persevering labours of the eminent ornithologists before named, seems to deserve being brought to a focus; and accordingly the following summary is now offered in the hope that some of the characteristics of the avifauna of the Region may thereby be more readily comprehended.

Distribution of peculiar families.

Of the families of Birds peculiar to the Neotropical Region—twenty-four in number, according to Messrs Sclater and Salvin—the distribution may be tabulated as follows:—

Subregion.	Peculiar to 1 Subregion	Common to 2 Subregions.	Common to 8 Subregions.	Common to 4 Subregions.	Common to 5 Subregions.	Common to all Subregions.
Patagonian	1[1]	3	1	1	3	0
Brazilian	0	4	1	8	5	0
Amazonian... .	1	0	1	8	5	0
Subandean	1	1	2	8	5	0
Central-American	0	1	1	7	5	0
Antillean . . .	1	0	0	0	2	0

This table will serve to shew the close alliance of the four middle Subregions to one another in their most remarkable forms, and, at the same time, the singularity displayed by the Patagonian and Antillean Subregions; while it will also make evident that no family peculiar to the Region is found in all its Subregions.

Patagonian Subregion.

(1.) *The Patagonian Subregion*, lying chiefly at the southern extremity of the continent, seems to present the greatest affinity to that in which the Australian avifauna reaches its climax. This is shewn not only by the prevalence in it, alone of all the Neotropical Subregions, of the *Ratitæ*, which wander over its solitudes, and the Penguins (*Spheniscidæ*), which haunt its shores; but by the low, generalized, and peculiar forms like *Thinocorus* and *Attagis* among the widely-varying *Limicolæ*, and the *Pteroptochidæ* (though some few species of this family occur elsewhere in South America) among the *Passeres*. The family of Plantcutters (*Phytotomidæ*) is almost peculiar, only just intruding upon Southern Brazil. Of the more characteristic families of Birds of the New World, some 3 only (*Dendrocolaptidæ, Formicariidæ*, and *Trochilidæ*) shew themselves in any great abundance, while but 2 others, which are feebly represented, occur within the ill-defined limits of its southern province, Patagonia,—the rest of its terrestrial, and still more of its littoral or maritime, avifauna consisting of families, or groups of families, which are nearly cosmopolitan. On the pampas of La Plata we find the number of characteristic Neotropical forms much increased, but still the poverty of the Argentine ornis is of the most marked kind when compared with the wealth of the more fertile tracts which lie on its northern and eastern frontiers. In La Plata we have but 2 other families (*Tyrannidæ* and *Palamedeidæ*) coming under this category that are at all well developed. *Mniotiltidæ, Vireonidæ*, and *Cœrebidæ* do not appear at all, and *Tanagridæ* but in small numbers. As has been said already, the Subregion extends northward along the chain of the Andes, and with this extension it seems proper to take in their arid and barren western slopes as well as a portion of the tract lying between that range and the sea, so as to include Chile and a considerable slice of Peru. But even by so doing we gain but little. No more of the characteristically Neotropical forms mount these lofty ascents in any multitude, nor are we able to add any forms of very wide distribution. However, throughout the whole Subregion many genera, and species without number, which are absolutely peculiar, occur, and thus aid in stamping the quality of the tract. Indeed, the very presence of the Struthious family *Rheidæ*, with its two or three species, would serve alone to do this, and as its headquarters are in Patagonia, that country becomes of sufficient importance to give its name to the Subregion of which it forms at most but a moiety.

Peculiar genera.

Entering more into details, we find the Patagonian Subregion possessing about 46 genera of birds not found elsewhere in South America. Of these 30 are strictly Land-birds—3 belonging to the family *Emberizidæ*, 1 to *Icteridæ*, 5 to *Tyrannidæ*, 8 to *Dendrocolaptidæ*, 4 to *Pteroptochidæ*, 3 to *Trochilidæ*, 1 to *Psittacidæ*, 1 to *Falconidæ*, 1 to *Columbidæ*, 2 to *Tinamidæ*, and 1 to *Rheidæ*. Of the rest there are 3 genera of *Charadriidæ* (as restricted), 1 of which (*Eudromias*) is doubtfully identical with a genus of the Old World; 2 genera of the peculiar family *Thinocoridæ; Chionis*, an antarctic form; 2 genera of *Scolopacidæ*, one peculiar, the other (*Rhynchæa*) rather widely spread over Australia, India, and Africa; 2 genera of *Anatidæ*, both peculiar; 2 genera of *Laridæ*, one peculiar, the other belonging to subpolar seas; 1 genus of the cosmopolitan *Podicipedidæ;* and 3 genera of *Spheniscidæ*, a family limited to the Antarctic or Subantarctic Ocean. But further into particulars want of space forbids our going, save to remark on a very peculiar and instructive case offered by *Eustephanus*, a genus of *Trochilidæ*. Of this section of Humming-birds there are three known species—one, *E. galeritus*, found in Chile, evidently its mother-country, but also occurring from 400 to 600 miles from the mainland on both of the chief islets of the little Juan Fernandez group—Masatierra and Masafuera; but each of these limited spots has besides its own peculiar species of the genus—the former *E. fernandensis* and the latter *E. leyboldi*. This alone would present nothing at all unparalleled elsewhere; but it is curious that while both sexes of the more widely-ranging *E. galeritus* have a green plumage, the males of the other two have a brilliant red colour, and generally resemble each other, though the females of each differ more decidedly. Supposing, as we may justly do, that all these species have descended from a common ancestor, Mr Sclater has shewn[2] the probability that *E. galeritus* represents the appearance of the parental stock that in bygone times colonized the Juan-Fernandez cluster, of which *E. fernandensis*, now peculiar to Masatierra, and the most aberrant from the original form, is the progeny of the earliest settlers, and *E. leyboldi*, confined to Masafuera, is the descendant of a later immigration, while, still more recently, *E. galeritus* has found its way to both islets, and in each yet possesses its normal characters.

Humming-birds of Juan Fernandez.

Passing over, as not affording anything especially remarkable, the chain of islands, from Chiloe to Cape Horn, in which the range of the Andes plunges into the Southern Ocean, though alongside of it lie Tierra del Fuego and its satellites, which form an important adjunct to the South-American continent, our attention is turned to the Falklands, an interesting and considerable group of islands situated over 200 miles to the north-east of the historic Strait of Lemaire. Here we find 18 species of Land-birds—7 belonging to the order *Accipitres* and 11 to *Passeres*. Of

Birds of Falkland Islands.

[1] The *Thinocoridæ* may be questioned as having a real existence. The writer would be inclined to include it in the cosmopolitan family of *Charadriidæ*.

[2] *Ibis*, 1871, pp. 180-188.

these some 5 species are peculiar—2 belonging to *Phrygilus* (*Emberizidæ*), 1 to *Cinclodes* (*Dendrocolaptidæ*), 1 to *Muscisaxicola* (*Tyrannidæ*), and 1 to *Milvago* (*Falconidæ*). Of Water-birds there is a peculiar species of *Chloephaga* (*Anatidæ*), and there are, or until recently were, about half-a-dozen species of Penguins (*Spheniscidæ*), some of which, though not resorting exclusively to these islands, may be fairly regarded as finding there their chief breeding-quarters. Of the ornithology of South Georgia, a group of islands lying some 1300 miles east of Staten Island, and nearly in the same latitude, and doubtless belonging to the Patagonian Subregion, as well as of the south Shetlands, no particulars are available.

Brazilian Subregion.

(2.) *The Brazilian Subregion* has only recently had removed from it the valley of the Amazons and its tributaries. The boundaries, so far as they can be traced, have been already given. This Subregion is not characterized by the presence of any family of Birds peculiar to it alone, but among those families which are found in only two Subregions of the Neotropical Region it possesses 3 in common with the Patagonian,—*Phytotomidæ*, *Cariamidæ*, and *Rheidæ*,—the first and last only in its southern districts, and 1 in common with the Central-American—*Oxyrhamphidæ*. Of the peculiarly Neotropical families occurring in three Subregions only, it has but 1, *Pteroptochidæ*, the range of which is shared by the Patagonian and the Subandean. When we come to families of four Subregions, we find the Brazilian invaded by the almost cosmopolitan *Sylviidæ*, which also inhabit the Subandean, Central-American, and Antillean, and possessing in common with the Amazonian, Subandean, and Central-American not fewer than 8—*Pipridæ*, *Momotidæ*, *Galbulidæ*, *Bucconidæ*, *Rhamphastidæ*, *Cracidæ*, *Heliornithidæ*, and *Parridæ*—the last of which is, however, widely distributed in other regions, besides, *Palamedeidæ*, which occurs also in the Patagonian, Amazonian, and Subandean Subregions. The chief justification for considering the Brazilian Subregion apart from the Amazonian is perhaps to be sought in the presence within the limits of the former of 5 families, *Sylviidæ*, *Oxyrhamphidæ*, *Phytotomidæ*, *Pteroptochidæ*, and *Cariamidæ*, which are not found in the latter, while on the other hand, 5 families, *Capitonidæ*, *Opisthocomidæ*, *Eurypygidæ*, *Psophiidæ*, and *Œdionemidæ*,[1] inhabit the latter without occurring in the former; add to which the fact, that of the families found in only two of the Neotropical Subregions not one is common to the Brazilian and Amazonian.

In this Subregion we have 42 peculiar genera, 1 belonging to *Sylviidæ*, 4 to *Tanagridæ*, 2 to *Emberizidæ*, 3 to *Tyrannidæ*, 2 to *Pipridæ*, 5 to *Cotingidæ*, 6 to *Dendrocolaptidæ*, 3 to *Formicariidæ*, 2 to *Pteroptochidæ*, 7 to *Trochilidæ*, 2 to *Caprimulgidæ*, and 1 to each of the families *Picidæ*, *Momotidæ*, *Galbulidæ*, *Psittacidæ*, and *Tinamidæ*. The number of peculiar species is, however, far too great to be here enumerated. There are no islands of any importance belonging to this part of South America.

Amazonian Subregion.

(3.) *The Amazonian Subregion*, comprehending the valley of the Amazons and its affluents (except their elevated sources among the Andes) as well as the right bank of the Orinoco and, of course, the intervening country, has been but lately separated from the preceding, and the reasons for here considering it distinct have just been briefly stated. They are not, indeed, those which first prompted the division, which was established mainly, if not entirely, on account of the peculiarity of most of the species of Birds[2] found within its ill-defined borders as before given; but on whichever ground we proceed we may be pretty sure that its separation is justifiable. We have here 2 families peculiar—*Opisthocomidæ*—already mentioned as forming almost a distinct Order, but composed of a single species, the Hoactzin, and the *Psophiidæ* or Trumpeters, now-a-days regarded as distant allies of the Cranes (*Gruidæ*), but presenting many remarkable and unique features. This family also contains but one single genus, including some half-dozen species, the respective range of each appearing, singularly enough, to be separated by rivers. Amazonia possesses no family in common with but one other Neotropical Subregion, but it shares 3 with the Central-American and Subandean. These are *Capitonidæ*, *Eurypygidæ*, and *Œdicnemidæ*, of which the second only is peculiar to the Region, the first and last being widely distributed. The families which it shares with three other Subregions have been already enumerated, as well as those which by their presence or absence distinguish it from the Brazilian Subregion. The peculiar genera remain to be pointed out. These are but 27 in number: 2 belong to *Icteridæ*, 3 to *Pipridæ* and *Cotingidæ* respectively, 2 to *Dendrocolaptidæ*, 7 to *Formicariidæ*, 2 to each of *Trochilidæ* and *Galbulidæ*, 1 to *Ardeidæ* and *Palamedeidæ*, 2 to *Cracidæ* and the genera *Opisthocomus* and *Psophia* before mentioned. There is another genus also which is worthy of remark, *Chenalopex*, belonging to the *Anatidæ*, not found elsewhere in the New World, but common to the Ethiopian Region. Space will not admit of our entering further upon the consideration of the ornithic peculiarities of Amazonia, but perhaps it may be said to form the most self-contained Subregion of the whole continental area of which we are now treating, and we may expect that with the progress of zoological exploration its boundaries may be laid down with tolerable precision. There are no islands which can be attached to Amazonia.

Subandean Subregion.

(4.) *The Subandean Subregion*, from what has been previously indicated of its extent, will be readily seen to offer the most varied conditions of existence of any part of the Neotropical Region, and we shall not therefore be surprised to find its ornis at once rich and remarkable. It might perhaps now, and some day probably will, be broken up into two or more provinces, not to say separated into distinct Subregions, but the means for such partition are at present wanting. Yet there is only one family of Birds peculiar to it, the *Steatornithidæ*, composed of a single species, the Guacharo or Oil-bird (*Steatornis caripensis*), confined to a very few localities in its eastern portion. In common with Central America, but not elsewhere met with in the Region, it has of Neotropical families *Cinclidæ* and *Alaudidæ*, though the latter of these two widely-ranging families is but poorly represented by a single species (*Otocorys chrysolæma*), apparently the survivor of an old population (all, or nearly all, of which has perished), stranded, as it were, on the high lands of Columbia. Those families which it possesses that are common to but two other Neotropical Subregions have already been named, and it will be enough to repeat that 1 of them extends to the Patagonian and Brazilian, and the remaining 3 to the Amazonian and Central-American. In like manner have been enumerated the families which are also found in but three other Subregions—1 it has in common with the Amazonian, Brazilian, and Patagonian; 8 with the Central-American, Amazonian, and Brazilian; while 1 of these (*Parridæ*) is also found in very distant parts of the world, and 1, also a family of extremely wide range, with the Brazilian, Central-American, and Antillean Subregions.

The genera peculiar to the Subandean Subregion are exceedingly numerous, amounting to no fewer than 72. These may be apportioned as follows: 1 to *Troglodytidæ*, 4 to *Cœrebidæ*, 10 to *Tanagridæ*, 5 to *Emberizidæ*, 1 to *Icteridæ*, 2 to *Tyrannidæ* and *Pipridæ* respectively, 3 to *Cotingidæ*, 1 to each of *Dendrocolaptidæ* and *Formicariidæ*,

[1] The propriety of considering the Stone-Curlews to form a family distinct from the other Plovers (*Charadriidæ*) is very questionable.

[2] *Cf.* Sclater and Salvin, *Proceed. Zool. Soc.* 1867, pp. 593-596.

38 (?) to *Trochilidæ*, 1 to the peculiar family *Steatornithidæ*, and 1 to *Picidæ*, *Strigidæ*, and *Cracidæ* respectively. The enormous differential development of the peculiarly New-World family *Trochilidæ* calls for some remark, and is only approached (as will presently be seen) by that which has occurred in Central America. The habitat of some of these forms of Humming-birds, whether genera or species—and the latter are wonderfully numerous—is extremely restricted. That of *Loddigesia mirabilis*, long since described from a still unique specimen in the Loddiges collection, is Chachapoyas in northern Peru, and though possibly more pains has been taken to discover it and compass the capture of other examples than has been the case with any other Bird, it has not been again met with. Its haunts may, therefore, be safely presumed to be especially confined. Two species of *Oreotrochilus* (*O. chimborazo* and *O. pichincha*) have their abode almost limited to the slopes of the lofty mountains whence they take their name, and nearly as much may be said of others. The Tanagers (*Tanagridæ*)—birds of varied form, and generally of exquisite plumage—also frequent this Subregion in great force, and among them there is here found, perhaps, the greatest amount of differentiation, both generic and specific.

Of the hundreds of other curious ornithological characteristics of the Subregion which might easily be cited, no more can here be given, but a brief notice of the avifauna of its extreme points seems to be required. It has now been for some time fully admitted by all competent authorities that the islands of Trinidad and Tobago, which the geographer might be inclined to class with the Antillean chain, must be regarded as being truly portions of the South-American continent, detached in comparatively recent times, and even now only separated from Venezuela by a comparatively shallow sea. Neither of these islands has a single peculiar species,[1] and except, perhaps, some stragglers from the north, not one which is not also found on the nearest mainland, though, of course, many inhabitants of the neighbouring continent do not pass either the Dragon's or the Serpent's Mouth, as the two narrow channels which cut off Trinidad from South America are called. We may presume that the various islands, Margarita, Curaçao, and Oruba, which lie off the northern coast of Venezuela, also belong to this Subregion, though scarcely anything is known of their animal products.

Trinidad and Tobago.

Very different from this state of things is that which obtains at the opposite extremity of the Subregion. The interesting group of volcanic islands known as the Galapagos present not merely a large number of peculiar species, but 4 peculiar genera of Land-birds; 1 of these, *Certhidea*, belongs to the *Cœrebidæ*, and the other 3, *Geospiza*, *Camarhynchus*, and *Cactornis*, seem to come into the family *Emberizidæ*.[2] It was Mr Darwin who first drew attention to the remarkable ornis of this archipelago, and here it was, as he has told us, that there dawned upon him from its consideration that theory of "Natural Selection" which has transformed the whole aspect of biology, and, whether wholly or partially accepted, has placed the science upon a new and higher pedestal. Later researches, indeed, have shown the nonexistence of some of the peculiarities which this eminent observer believed, on what was then good evidence, he had determined; but these refer to the restricted distribution of several of the species among the different islands, and are not of any such importance as to affect his general results, while doubtless, had his visit to this "little world within itself," as he appropriately calls it, been of longer duration, he would have become aware of these minor facts. The strictly-speaking Land-birds of the Galapagos seem to be some 30 in number, of which about 26 are *Passeres*. Among these, 1 only, *Dolichonyx oryzivorus* (belonging to the family *Icteridæ*), and obviously a straggler, is identical with a species of the mainland, while 2, a *Dendrœca* (*Mniotiltidæ*), and a *Progne* (*Hirundinidæ*), have been by some considered to be distinct species, by others but local races,—which means, of course, that from one cause or another isolation has not yet modified them so as to depart greatly from their congeneric continental forms,—but the remaining 23 (?) are peculiar, and, what is especially worthy of notice, no fewer than 18 (?), or nearly three-fourths of the whole number, belong to the four peculiar genera. There is also a peculiar species of Buzzard, agreeing closely in every habit and even in tone of voice with the carrion-eating *Polybori*, and originally described as the type of a distinct genus under the name of *Craxirex galapagoensis*. Apparently, too, there is a distinct and peculiar Barn-Owl (*Aluco punctatissimus*), but alongside of it we have the widely-spread Short-eared Owl (*Asio accipitrinus*), though examples of this last are said to present in these islands sufficient difference to justify the bestowal upon them of a distinct specific name. Among Water-birds, the *Rallidæ* and *Ardeidæ* furnish, the former one and the latter two, species not known elsewhere. A remarkable fact, also, is the asserted existence of a peculiar species of Flamingo (*Phœnicopterus glyphorhynchus*), seeing that most of the birds of this genus have a very extended distribution. A Penguin also (*Spheniscus mendiculus*) is at present only known from the Galapagos; but considering the range of other forms of this family (*Spheniscidæ*), we should, perhaps, be premature in as yet pronouncing it a peculiar species, though the existence of a Penguin at all under the equator raises a presumption that such may be the case. There is, however, one feature in the avifauna of these islands which should not be overlooked. Notwithstanding that the Galapagos are here placed as forming an outlying portion of the Subandean Subregion, the fact must not be concealed that their ornis seems to have no very special or intimate relation thereto. All that can be averred of it is that it is American. In the subregion just named, as has been above shown, the *Trochilidæ* attain their maximum of development, yet no Humming-birds are found in this archipelago. So also with the *Tanagridæ*, of which there are abundant Subandean representatives, the *Dendrocolaptidæ*, *Formicariidæ*, and other characteristic Neotropical families. In the Galapagos none of them are found. It is true that the presence of a species of the South-American genus *Pyrocephalus*, and of a genus of the Neotropical family *Cœrebidæ*, may be a set off on the other side; but on the whole, it seems quite likely that the relations of this isolated, equatorial province (for so it is entitled to be deemed) are as near to the north as to the south, if not nearer, and it is quite possible that, having its ornithological characters only in view, future zoogeographers may think fit to ally it to the former rather

Galapagos.

Their Subregional assignation doubtful.

[1] Trinidad has about 350 species—one of them (*Psittacula cingulata*) was thought to be peculiar, but Mr Salvin informs the writer that it has lately been procured in Guiana. The nearest approach, perhaps, to peculiarity is in a Thrush, which was originally described as being specifically distinct, under the name of *Turdus xanthoscelus*, but its claims to that consideration are now disallowed.

[2] A very considerable amount of uncertainty, which at present cannot be removed, though it produces some confusion, appertains to the right position of many of the New-World forms of so-called Buntings (*Emberizidæ*) and Finches (*Fringillidæ*). The writer is fully inclined to believe that the distinctness of these two families, which among forms of the Old World has long been recognized, and that almost without difficulty, can be fairly established, since it seems to rest on good osteological characters; but the American genera have not yet been sufficiently examined to allow of many of them being allotted without much doubt. This uncertainty will most likely in time be removed, unless—and such a probability cannot be denied—some of the New-World forms turn out to be so much generalized as to fill up the gap which now presents itself between the two groups as observed in the Old World. Meanwhile, the consequent inconvenience is unavoidable.

than the latter. But the affinities of its Reptilian fauna point to a connection, however remote in point of time, with South America, and accordingly the Galapagos are here left in that Region to which they have been commonly assigned.

Central-American Subregion.

(5.) *The Central-American Subregion* is the next to be considered, and in treating of it we become aware of a disturbing force which renders impossible the laying down for it of anything like a definite frontier. This disturbing force is the entrance, as before intimated, of a Nearctic fauna which runs along the backbone, so to speak, of the Subregion to an unknown but variable extent; for part of this Nearctic fauna ebbs and flows according to the season of the year, in winter possibly creeping down the mountain-sides, and being strongly reinforced by immigrants from the north, but in summer retiring northward and perhaps upward, so as to occupy only the most lofty ridges. Yet that two Subregions here unite and inosculate is certain; but in considering the Central-American avifauna, we have to guard ourselves against this periodic stream of northern immigrants, and cannot deal with it precisely in the same way as we have done those Subregions further removed from the influence which is here so strongly manifested. In Central America, though its ornis is of the richest, we find not a single peculiar family of Birds, and those which it, to a more or less limited extent, shows with the other Subregions of the Neotropical Region have been already named, except the *Ampelidæ*, a small but widely-ranging family of the northern hemisphere, which it has in common with the Antillean Subregion. 5 other families, however, *Paridæ*, *Sittidæ*, *Certhiidæ*, *Laniidæ*, and *Meleagridæ*, belonging also to the Nearctic Region, occur here. Of genera which are not found elsewhere in the Region, it seems to have 93, but 47, or just more than half, of them are also found in the Nearctic Region; and therefore to obtain anything like a true notion of the Central-American ornis, it will be necessary to keep the two categories apart. Taking first those which are absolutely peculiar, we have 2 belonging to *Turdidæ*, 1 to *Troglodytidæ*, 2 to *Mniotiltidæ*, 1 to each of *Vireonidæ*, *Ampelidæ*, and *Tanagridæ*, 3 to *Emberizidæ*,[1] 1 to *Icteridæ*, 2 to *Corvidæ* and *Tyrannidæ* respectively, 1 to *Cotingidæ*, 2 to *Formicariidæ*, 19 to *Trochilidæ*, 2 to *Momotidæ*, 1 to each of *Trogonidæ*, *Cuculidæ*, and *Psittacidæ*, 2 to *Cracidæ*, and 1 to *Tetraonidæ*. Then, taking those not found elsewhere in the Neotropical Region, but inhabiting the Nearctic, we have, as occurring in Central America, 1 belonging to *Turdidæ*, 2 to *Sylviidæ*, 3 to *Paridæ*, 1 to each of *Sittidæ* and *Certhiidæ*, 2 to *Troglodytidæ* and *Mniotiltidæ* respectively, 1 to *Laniidæ*, 2 to *Ampelidæ*, 14 to *Emberizidæ*,[1] 3 to *Fringillidæ*, 2 to *Icteridæ*, 1 to each of *Tyrannidæ*, *Trochilidæ*, *Picidæ*, and *Cuculidæ*, 2 to *Strigidæ* and *Anatidæ* respectively, 1 to each of *Columbidæ* and *Meleagridæ*, 2 to *Tetraonidæ*, and 1 to *Charadriidæ*.

Nicely balanced as these numbers are, they shew a result which might well have been expected from the physical and geographical configuration of the country, while the numbers of other families peculiar to the Neotropical Region, though shared by some of its Subregions, as already given, prove incontestably the propriety of including Central America with that Region; and this would come out even more plainly did our limits permit of the investigation being extended to species, though so many northern forms here find their winter-quarters. It remains to remark that almost the only island of any importance belonging to the Subregion is Socorro, the largest of a small group lying to the westward of Mexico in lat. 18° 30′ N., and long. 111° W. Here out of 9 species of Land-birds, 4 have been described as peculiar, 2 others are elsewhere known as occurring only on the Tres Marias, a little group some 250 miles nearer the mainland, and 1 is regarded as a local race of a continental species, leaving but 2 (both Birds-of-prey) which cannot be deemed autochthonous. The still more remote Cocos Island, lying in lat. 5° 33′ N., and long. 87° W., from which one peculiar species of *Coccyzus* (*Cuculidæ*) is known, may belong just as likely to the Subandean as to the Central-American Subregion.

Antil Subre

(6.) *The Antillean* is the only one of the Neotropical Subregions the precise boundaries of which can be definitely laid down; and it is in many respects one of the most suggestive and interesting, comparatively small though it be. Extending from Cape San Antonio de Cuba in the west to Barbadoes in the east, its greatest length is only about 1700 miles, and from Abaco, one of the Bahamas, in the north to Granada in the south, it does not cover 15 degrees of latitude, while within these limits the proportion of land to water, being less than 98,000 square miles, is very inconsiderable. The unbroken chain of islands which are commonly known as the "West Indies"—though that term rightly includes not only all of the "Spanish Main," but an indefinite extent of coast lying both north and south of the ancient dominions of the Catholic King in the New World - forms, geographically, a second line of connection between the two halves of the American continent, separated from the great western isthmus by the deep waters of the Caribbean Sea and the Gulf of Mexico, and at once suggests a former communication by land with Yucatan at the one extremity and with Venezuela at the other, to say nothing of a possible junction with Florida. Yet, as will presently be shewn from a consideration of the peculiar forms of Bird-life which have grown up along the chain, any such communication, if it ever existed, must have been exceedingly remote in point of time; for narrow as are the channels between Cuba and the opposite coast of Central America, between the Bahamas and the south-western peninsula of North America, and between Grenada and Tobago (the last belonging zoologically, as has been already demonstrated, to South America), the fauna of the Antillean chain, instead of being a mixture of that of the almost contiguous countries, differs much from all, and exhibits in some groups a degree of speciality which may be not unfitly compared with that of oceanic islands. Except such as are of coral formation, the Antilles are hilly, not to say mountainous, their summits rising in places to an elevation of 8000 feet, and nearly all, prior to their occupation by Europeans, were covered with luxuriant forest, which, assisting in the collection and condensation of the clouds brought by the trade winds, ensured its own vitality by precipitating frequent and long-continued rains upon the fertile soil. Under such conditions we might expect to find an extremely plentiful animal population, one as rich as that which inhabits the same latitudes in Central America, not many degrees further to the west, but no instance perhaps can be cited which shows more strikingly the difference between a continental and an insular fauna, since, making every allowance for the ravages of cultivation by civilized man, the contrary is the case, and possibly no area of land so highly favoured by nature is so poorly furnished with the higher forms of animal life. Here, as over so large a portion of the Australian Region, we find Birds constituting the supreme class—the scarcity of Mammals being accounted for in some measure as a normal effect of insularity.

Glancing at the entire chain, we may first set aside the Bahamas, a succession of emerged coral-reefs founded on, and to the south and east surrounded by, shoals or banks, broken only here and there by deeper channels; and then, by drawing a line to the south of the islands of St Croix

[1] See preceding footnote.

and St Bartholomew, we find that this line divides the chain into two groups of distinct character—that lying to the southward and eastward, almost identical with the "Windward Islands" of some geographers,[1] which, excepting Antigua and Barbadoes, are almost entirely volcanic, while no direct trace of recent volcanic action is known in the group lying to the northward and westward. These three divisions, however natural in appearance, can hardly be affirmed to form as many zoological provinces, owing to the absolute dearth of information respecting many of them, and the insufficient amount which has been received of the remainder. Taking the whole of the Antillean Subregion, the Bahamas, Cuba, Jamaica, St Croix, St Thomas, Sombrero, St Bartholomew, Guadaloupe, Dominica, Martinique, and St Lucia are the only islands of the ornithology of which we have anything more than what may be called a casual account; and hence, though valuable observations respecting some of the rest have been placed on record by travelling naturalists, any attempt to separate the Subregion into proper provinces would necessarily be of the crudest kind, and here cannot be made, though doubtless such provinces will eventually be defined with precision.

Characteristic families and genera.

Still enough is known of the Birds of this Subregion to enable us to draw some conclusions, though certain of them seem especially likely to be overset by further investigation. It is inhabited by some 41 families, 1 of which (*Todidæ*) is not found elsewhere, 2 more (*Cœrebidæ* and *Cotingidæ*) are confined to the Neotropical Region, 8 (*Mniotiltidæ, Vireonidæ, Tanagridæ, Icteridæ, Tyrannidæ, Trochilidæ, Cathartidæ*, and *Aramidæ*) are common to that and the Nearctic Region, but are peculiar to the New World, and 30 are of much more general distribution, but 2 of these (*Trogonidæ* and *Fregatidæ*) are not found in the Nearctic Region, and, as the above numbers show, there is no family common to that Region and the Antillean Subregion without also occurring in other parts of the Neotropical Region. On the whole, therefore, the affinity of the Subregion to the Neotropical rather than to the Nearctic Region is fully made out. About 140 genera are found in the Antilles, of which 30 are peculiar to it, being a considerably larger proportion than is elsewhere found in the Neotropical Region. Of these 30 genera, which are all Land-birds, 4 belong to *Turdidæ*, 1 to each of *Mniotiltidæ, Vireonidæ, Ampelidæ*, and *Cœrebidæ*, 2 to *Tanagridæ* and *Emberizidæ* respectively, 1 to each of *Icteridæ* and *Tyrannidæ*, 5 to *Trochilidæ*, 1 to *Caprimulgidæ*, 2 to *Picidæ*, 1 to *Todidæ*, 2 to *Trogonidæ, Cuculidæ*, and *Strigidæ* respectively, and 1 to *Columbidæ*.[2] Besides these, 21 more, which it is perhaps unnecessary to particularize, do not exceed the limits of the Neotropical region, while 5 others, belonging respectively to the families *Cypselidæ, Fregatidæ, Anatidæ, Columbidæ*, and *Rallidæ*, occur both here and elsewhere in that Region without reaching the Nearctic except as stragglers. *Perissoglossa*, belonging to the family *Mniotiltidæ*, is the only genus common to the Nearctic Region and the Antillean Subregion without occurring elsewhere in the Neotropical Region, all the remaining Antillean genera inhabiting both North and South America. The distribution of some of the peculiar genera merits a little attention, for 19 out of the 30 are confined to a single island, or nearly-connected group of islands. Thus, Cuba has 6 believed to be restricted to its soil; Jamaica, 7; Hispaniola, 2; and the so-called "Windward Islands," probably 4; while none are known to be absolutely limited to the Bahamas, to Porto Rico, or the Virgin Islands. It is possible, indeed, that Hispaniola and Porto Rico, if as well explored as Cuba and Jamaica have been, might tell a very different story.

Resident and migrant species.

Pursuing the subject further, and entering, so far as space will allow, upon a consideration of details, we find that there are of Land-birds about 200 resident species, and nearly 90 which are not resident, but migratory. These last belong to about 55 genera, of which some 40 have no resident insular representatives, while those migrants pertaining to genera which possess permanent residents are nearly all as much Neotropical as Nearctic in character. Most of these, so far as is known, visit Cuba only, where over 80 are recorded as occurring, while but 30 reach Jamaica. The number, however, in the island last named, and in others, would most likely be not inconsiderably increased did competent observers but exist, though the fact that a well-known species like the Humming-bird of eastern North America (*Trochilus colubris*) does not seek its winter-abode in any of the islands except the Bahamas and Cuba, tends to lessen the force of such a supposition, and points to our actual knowledge being not very far wrong. Among the more interesting of peculiar forms is one genus of *Turdidæ* (*Mimocichla*), which is represented by 4 distinct species, found in the Bahamas, Cuba, Jamaica, and Hispaniola respectively. Another genus of the same family (*Margarops*) has a species ranging from Hispaniola to the Virgin Islands, and a second species inhabiting Martinique and St Lucia only, these two islands possessing at the same time a third and peculiar genus (*Rhamphocinclus*), containing but a single species, common to both, while they also have another genus (*Cinclocerthia*), a distinct species of which inhabits either island, though a third species of the same is found in Guadaloupe and Nevis. The genus *Certhiola*, belonging to the *Cœrebidæ*, is remarkable in that it occurs in nearly every island except Cuba; but what seems to be still more extraordinary is that the species found in the Bahamas (*C. bahamensis*), and there alone in the whole Subregion, also occurs in Cozumel, an island off the coast of Yucatan, though Cuba intervenes. The distribution of *Spindalis*, one of the *Tanagridæ*, resembles that of *Mimocichla*, above noticed, only that here Porto Rico also has its distinct representative species. Of the peculiar genera of Humming-birds, *Eulampis* has 2 species—one ranging from St Lucia to Nevis, but the second extending northward to St Thomas. *Aithurus*, a very remarkable form, is restricted to Jamaica, while *Mellisuga* is common to that island and Hispaniola—each of these genera consisting of but one species only, and the last is the smallest known bird. *Orthorhynchus* seems to have 3 species, one extending from St Thomas to Dominica, a second (perhaps barely separable) common to Martinique and St Lucia, and a third to St Vincent and Barbadoes; and, finally, *Sporadinus* has one species in Cuba and at least one of the Bahamas, a second species in Hispaniola, and a third in Porto Rico. Of genera of Humming-birds, which are not confined to the Antilles, *Lampornis*, a widely-ranging genus, has two species peculiar to Jamaica and Porto Rico respectively; while a third extends from Hispaniola to St Thomas. *Calypte*, which has two species in Mexico, has a third peculiar to Cuba, while *Doricha* is represented in two of the Bahamas (New Providence and Inagua) by as many distinct species; the other three described species of the form inhabiting Central America, and none, so far as known, occurring in

[1] In the language of others, the "Windward Islands" begin with Martinique and so continue to Trinidad, while the remainder of the Lesser Antilles, lying eastward of Porto Rico, are called the "Leeward Islands." Other authorities name all the smaller islands so far as St Thomas "Windward Islands," and those further westward the "Leeward." Creoles appear to apply these terms relatively to their own habitation, just as the dweller on the bank of a river speaks of "up stream," and "down stream" with sole reference to the position he occupies on the margin; and it might be wished, though that were vain, that the use of terms so little definite should be abandoned.

[2] This genus (*Starnœnas*) has been said, however, to occur in the Florida Cays, but the statement seems doubtful.

Cuba; and thus we have afforded us another case of interrupted generic distribution somewhat like though not quite so extraordinary as that of *Certhiola* already noticed. In all, about 17 species of *Trochilidæ* are found in the Antilles, of which only one, and that of exceptionally developed migratory habits, occurs elsewhere. The peculiar family *Todidæ* has been already mentioned; and it is only necessary here to remark that the single genus *Todus* which it contains seems to have 5 species, one limited to each of the large islands, Cuba, Jamaica, Hispaniola, and Porto Rico, the fifth being from an unknown locality.[1] Much the same has to be said of *Saurothera*, a genus of *Cuculidæ*, which is represented by a distinct species in each of these four islands, while another genus of the same family, *Hyetornis*, with one species, is peculiar to Jamaica. The *Trogonidæ* have two genera, *Prionoteles* and *Temnotrogon*, each with a single species, the former peculiar to Cuba, and the latter, which exhibits a remarkable affinity to the African genus *Hapaloderma*, to Hispaniola. *Pseudoscops*, a genus of *Strigidæ*, is peculiar to Jamaica, but *Gymnoglaux*, belonging to the same family, has one species limited to Cuba, while a second extends from Porto Rico to some of the Virgin Islands. Cuba also, besides a widely-ranging species of Kestrel (*Tinnunculus*), has a second species which is peculiar to the island. Jamaica, on the other hand, seems to have no Kestrel at all.

Any speculations as to the former history of the Antilles derived from our imperfect knowledge of their existing ornis would be vain. It is enough to perceive, as the preceding facts will show, that there must here have been no ordinary amount of upheaval and subsidence, of turning land into water and water into land, to account for the present distribution of their avifauna. More wonderful than any evidence given by the Birds, is that which is afforded by other Classes. It is asserted that *Solenodon*, an Antillean genus of Insectivorous Mammals, has its nearest ally in a Malagasy form; and a splendid Butterfly, found only in Jamaica (*Urania sloanii*), belongs to a genus of which while two other species are known from Central and South America respectively, the only other genus resembling it is one that inhabits Madagascar.

NEARCTIC REGION. Boundaries.

III. THE NEARCTIC REGION comprises all that is left of the American continent, after the Neotropical Region has been taken off, and certain outlying groups of islands, such as the Aleutian chain, with its immediate dependencies, and the Bermudas—none of them, however, being of any great importance,—as well as the circumpolar lands lying westward of long. 60° W., and Greenland. The confines of these two Regions, as before stated (page 748), are as yet but vaguely traced. All that is known for certain is that the more northern runs considerably southward along the highlands of Central America, and that its influence, as determined by the presence of resident genera of northern extraction, is perceptibly felt on the summits or slopes of the mountains, at least so far southward as lat. 20° N. In the lowlands the boundary lies much further towards the north, and, perhaps, in general terms, may be placed somewhere about lat. 25° N., while both in lowlands and highlands, as above explained, the northern influence varies with the seasons of the year, being greatest in winter, when the migratory birds, which breed in the Nearctic Region, have turned their flight southward, and least in summer, when they have retired to their northern homes.

General characteristics.

If the avifauna of the Neotropical Region could, in a wide sense, be truly termed homogeneous, much more is this the state of the case with the Nearctic. Of the 63 families[2] of Birds, which is the highest number that it seems possible to count for this region, only 1, *Chamæidæ*, is peculiar, and the validity of the grounds on which this has been established as such may be open to question; 44 of them are also Palæarctic; and the remaining 18 are common to the Neotropical Region, of which last number at least 4 (*Trogonidæ*, *Plotidæ*, *Fregatidæ*, and *Phaetontidæ*) have a much more extended range. Thus there are 14 peculiarly American families left. These are *Mniotiltidæ*, *Cœrebidæ*, *Tanagridæ*, *Vireonidæ*, *Icteridæ*, *Tyrannidæ*, *Trochilidæ*, *Momotidæ*, *Aridæ*, *Cathartidæ*, *Cracidæ*, *Meleagridæ*, *Tantalidæ*, and *Aramidæ*. But the propriety of here admitting *Trogonidæ* (mentioned above) and *Momotidæ* is very doubtful; for, though included by Dr Coues, they are omitted by Professor Baird from his *North American Birds*, the most recent work on the subject. The claim of *Cœrebidæ* to be considered Nearctic is also slender, resting on the fact that a small colony of the Sugar-bird which inhabits the Bahamas (*Certhiola bahamensis*) has established itself on one of the Florida Cays. The *Aridæ* are represented in the Region by a single species only—the long-known Carolina Parrakeet (*Conurus carolinensis*); and the *Tanagridæ*, a family containing upwards of forty genera, have but one genus (*Pyranga*), exemplified by four or five species, out of about a dozen, which occur within its limits.

On the other hand, the peculiarly American families best represented in the Nearctic Region seem to be four in number,—*Mniotiltidæ*, by 13 genera and about 50 species, *Vireonidæ* by 1 genus and 14 species, *Icteridæ* by 8 genera and 21 species, and *Tyrannidæ* by 8 genera and 26 species. The first of these, however, can alone be regarded as eminently characteristic of the Region, since that affords a home to all but 3 of the genera, but at the same time, only about one-half of the described species occur there. None of the rest can compare with it in this respect, *Vireonidæ* having 5 genera and 50 species, *Icteridæ* 24 genera and 105 species, and *Tyrannidæ* 71 genera and 324 species in the Neotropical Region.

Coming now to the genera of Nearctic birds, we may put the number perhaps at 330, of which 24 seem to be peculiar to the Region; 2 of them belong to *Turdidæ*, 1 to *Chamæidæ*, *Paridæ*, *Troglodytidæ*, and *Motacillidæ* respectively, 5 to *Emberizidæ*, 2 to *Corvidæ*, 1 to each of *Picidæ*, *Falconidæ*, and *Columbidæ*, 5 to *Tetraonidæ*, and 1 to *Scolopacidæ*, *Anatidæ*, and *Laridæ* respectively. But it is perhaps worth remarking that the families *Emberizidæ* and *Tetraonidæ*, here most abundantly represented by genera, are still more abundantly represented in like manner elsewhere.

Relation to other Regions.

In the Neotropical Region we have some 30 and in the Old World some 15 genera of the former, which are not found in the Nearctic Region; and the Old World has some 30 genera of the latter which are not found in the New. On the other hand it must be admitted that if we subdivide the American *Tetraonidæ* into sections or subfamilies, we find that while one of those sections, the *Odontophorinæ*, is peculiar to America, the balance as regards the other, *Tetraoninæ*, is clearly in favour of its greater development in North America, where we have 3 genera absolutely peculiar, as well as 3 others which are also found in the Palæarctic Region. With this Region, indeed, the Nearctic has about 128 genera in common, having 178 which are also Neotropical. Returning to these last presently, it may be advisable here to give some particulars of those which are common to both sides of the North Atlantic. 1 belongs to each of the families *Turdidæ* and *Cinclidæ*; 3 to *Sylviidæ*, 2 to *Paridæ*, 1 to *Sittidæ*, *Certhiidæ*, *Troglodytidæ*, and *Alaudidæ* respectively, 2 to each of *Mota-*

[1] A bird of this group was one of those asserted by Ledru to have formerly occurred in St Thomas (page 734).

[2] Three of these (*Hæmatopodidæ*, *Recurvirostridæ*, and *Phalaropodidæ*) are not regarded as good families by the writer. They are all common also to the Palæarctic Region.

cilidæ and *Hirundinidæ*, 1 to *Ampelidæ* and *Laniidæ* respectively, 7 to *Fringillidæ*, 2 to *Emberizidæ*, 3 to *Corvidæ*, 1 to each of *Cypselidæ* and *Alcedinidæ*, 3 to *Picidæ*, 9 to *Strigidæ*, 10 to *Falconidæ*, 1 to *Columbidæ*, 3 to *Tetraonidæ* and *Charadriidæ* respectively, 2 to each of *Hæmatopodidæ*, *Recurvirostridæ*, and *Phalaropodidæ*, 7 to *Scolopacidæ*, 1 to *Ibididæ* and *Plataleidæ* respectively, 4 to *Ardeidæ*, 1 to *Gruidæ*, 5 to *Rallidæ*, 1 to *Phœnicopteridæ*, 18 to *Anatidæ*, 1 to each of *Sulidæ*, *Pelecanidæ*, and *Phalacrocoracidæ*, 6 to *Laridæ*, 3 to *Procellariidæ*, 1 to each of *Colymbidæ* and *Podicipedidæ*, and 10 to *Alcidæ*.[1] Thus it will be seen that no less than 57, or more than *one-sixth* of the whole 330 genera, are purely Land-birds,—a very large proportion.

The genera which occur both in the Nearctic and Neotropical Regions, without appearing in the Palæarctic, must be divided into two categories in order to arrive at a just estimate of the relations of the avifaunas of the first two. These categories consist of those genera which, being only winter visitants to the southern Region, do not breed there, and those which may fairly be called common to both. The latter need perhaps no further attention, after what has been previously said of the Central-American Subregion (p. 748), but the former require some notice. Of those in this category 1 genus belongs to each of the families *Sylviidæ* and *Troglodytidæ*, 8 to *Mniotiltidæ*, 6 to *Emberizidæ*, 1 to *Icteridæ*, *Trochilidæ*, *Picidæ*, and *Columbidæ* respectively, 6 to *Scolopacidæ*, and 1 to *Phalaropodidæ*—27 in all. These must, of course, be considered characteristic of the Nearctic Region, and might, indeed, be not inappropriately added to the 24 genera which are, as already said, peculiar thereto; but even if this be done, we find the number of peculiar and characteristic genera (taken together) of the Nearctic Region to be only 51—a smaller number than that of the genera of Land-birds alone (57) which are common to the Palæarctic, and considerably less than half the number of all genera which are found on both sides of the Atlantic (128), while the remaining genera which are strictly common to the Neotropical (151) is much larger again. Thus, regarded simply from an ornithologist's point of view, what we call the Nearctic "Region" seems to have no right to be considered one of the primary Regions of the earth's surface, and to be of less importance than some of the Subregions of the Neotropical Region, as may be shewn more plainly by the following table:—

	Whole No. of Genera of Birds.	Peculiar Genera of Birds.
Patagonian Subregion	290	46
Brazilian ,,	396	43
Amazonian ,,	373	27
Subandean ,,	469	72
Central-American ,,	464	46
Antillean ,,	140	30
Nearctic Region	330	24

It is not, however, intended here to question the validity of the Nearctic Region in a zoogeographical sense. If that position could be successfully disputed, it must be done on more than ornithological grounds, and a consideration of them would be out of place in this article. It is enough to mention that though the Mammals would possibly lead to much the same conclusion as the Birds do, yet the lower Classes of Vertebrates—Reptiles, Amphibians, and Fishes—would most likely have a contrary tendency, while the present writer is quite unable to guess at the result which would be afforded by the Invertebrates. Now, as in mapping out the world into zoological Regions all animals have to be regarded, he has no wish to disturb the scheme which has been so generally approved, but contents himself with pointing out that the case for its adoption is not in this particular instance strengthened by the evidence given by the Class *Aves*.

A great majority of the Nearctic families and genera of Birds appear to be generally distributed throughout all the "Subregions," or perhaps it would be better to call them "provinces," into which ingenuity can separate the Region. And on this account, as well as from what has been urged in the preceding paragraph, it seems unnecessary to treat of each "Subregion" or "province" so fully as has hitherto been done in the present article. Indeed such districts are not easily defined, and their definition rests rather on differences of species than of higher groups, as we have found to be the case in discussing the several component parts of the other Regions we have considered. Professor Baird, in a masterly treatise on this and another subject,[2] would first divide that portion of North America which constitutes the Nearctic Region into *two* principal sections, the Eastern extending from the Atlantic sea-board westward across the Alleghany Mountains, and over the valley of the Mississippi and its fertile prairies to about long. 100° W., where the sterile plains begin. The western boundary of this division, however, is not sharply defined, nor does it coincide with any meridian line, but lies somewhat obliquely and interdigitates with the eastern confines of the next division by extending westward along the river-bottoms. Marching with this irregular frontier we have the second, or Western, great division reaching thence to the shores of the Pacific, and though the character of its avifauna is much the same through and beyond the Rocky Mountains to the eastern slope of the Sierra Nevada and Cascade Mountains of California and Oregon, it changes somewhat on their western slope and thence to the sea, exhibiting modifications which may warrant further separation into a truly Western and a Central subdivision—thus making in all *three* provinces for the whole of the more southern part of the Nearctic Region, while each of them shews, as might be expected, indications of additional change, subject in great measure to the degree of latitude under which any particular locality in them may lie.

Division into sections and provinces.

Having thus pointed out the three provinces into which this portion of the Region can be separated, it may be well to cull from Professor Baird's investigations of the subject some further details. The boundary of the Eastern province, which, taking up an old name, we may perhaps term the "Alleghanian"—from the principal mountain range within its limits,—starts from the Gulf of Mexico, near the eastern border of Texas, perhaps between the rivers Brazos and Sabine, and following the course of the former to the great American Desert, in about long. 100° W., runs northward, forced sometimes more or less westward, especially along the Platte, and sometimes eastward. It crosses the Platte between Forts Kearney and Laramie, and apparently intersects the Missouri about Fort Lookout. Reaching the southern frontier of the Dominion of Canada, it rapidly inclines to the westward, and including the valleys of the Saskatchewan and the Athabasca, it crosses the Rocky Mountains, and, cutting the river Yukon below the junction of the Pelly and the Porcupine, loses itself in the wilds which border the Arctic Ocean. Since the Middle province—on which as yet no more precise name has been bestowed—lies for the most part between the Alleghanian and the Western or "Californian," as it has been entitled, the boundaries of this last had best, so far

Alleghanian province.

Middle province.

[1] Of many American Birds, especially Water-birds, which from time to time occur as stragglers in Europe, no account has here been taken, and, of course, they will not be reckoned in our computation of Palæarctic genera.

[2] "The Distribution and Migrations of North American Birds," *American Journal of Science and Arts*, ser. 2, vol. xli. pp. 78–90, 184–192, 337–347 (January, March, and May, 1866).

as is possible, be given. Its extent both southward and northward is somewhat indefinite. The avifauna of Cape San Lucas, at the extremity of the peninsula of Old or Lower California, is said to be thoroughly that of the "Middle" province, but whether the whole of that promontory is to be reckoned as belonging thereto, or only its eastern border, is not known. It appears, however, that some of the most characteristic forms of the Middle province find their way to the Pacific coast through a break in the mountains opposite to San Diego, and it is to be remarked that the difference between the species of birds found at Cape San Lucas (of which about a score are absolutely peculiar) and of Mazatlan, though separated only by the breadth of the Gulf of California, is very great. Northward the boundary of the Californian province probably runs along the Sierra Nevada and the Cascade Mountains before named, so that its extent is contracted to a mere strip along the coast, while still further to the north, in British Columbia, no precise details of its limits have as yet reached this country. But it would seem that in Alaska, as will presently be stated at greater length, an avifauna presenting many very different characters from any found elsewhere in America is reached, for here we encounter a number of genuine Palæarctic forms.

Californian province.

Canadian province.

But these are not all the zoological provinces into which this part of North America can be separated. A *fourth*, of especially Arctic type, occupies the northern portion of the continent, and gradually melts away into the rest, extending far to the southward along the highest ranges, even to Fort Burgwyn, in lat. 37° N., if not beyond. This province may be called the "Canadian," from the ancient colony of that name constituting so large a portion of it, but its limits must be confessed to be indefinite in a high degree. The eastern half, at least, of the British possessions in North America are herein included, and the province may be deemed to extend across Davis's Strait to Greenland.

In noticing these provinces, the results of Professor Baird's researches have been, with little deviation, mainly adopted, but his enquiries have been largely supplemented by the more recent investigations of Mr J. A. Allen, who has admirably carried out the further subdivision of the Eastern, or, as it has been termed, the Alleghanian province, together with part of what has just been denominated the Canadian. Regarding the whole eastern half of the continent as one province, he recognises in it the existence of seven distinct ornithological faunas, namely, the Floridan, the Louisianian, the Carolinan, the Alleghanian, the Canadian, the Hudsonian, and the American-Arctic, comparing them also with the distribution therein of Mammals and Reptiles.[1] To describe more fully the boundaries of these faunas would be to enter on matters too special for our present purpose, and it must suffice to direct attention to this essay of Mr Allen's, which, like others of his,[2] though their titles may seem to indicate for them but a limited scope, has, in truth, a very general bearing.

Peculiar distribution of families.

The provinces above named (and naturally the districts which they comprise) appear to be characterized rather by the presence or absence of certain species of widely-spread genera than by the presence or absence of the genera themselves, and much less of families, but it seems expedient to notice some of the chief exceptions to general distribution in the latter of these groups. First we have the peculiar family of *Chamæidæ*, restricted so far as is known to the coast-district of California, where it is represented by a single genus and a single species; and then among families of greater range, the *Cœrebidæ*, already introduced to us as a Neotropical group, but in the Nearctic Region existing only in the case of the colony of a species of *Certhiola* before noticed; the *Aridæ*, nowadays almost limited to Western Louisiana, Arkansas, and Florida, but formerly known along the whole valley of the Mississippi to the verge of the Great Lakes, and even occasionally penetrating to Pennsylvania and the State of New York; the *Cathartidæ*, of which one genus (*Pseudogryphus*), having for its sole species one of the largest birds of flight, the Californian Vulture (*P. californianus*), is confined to the Pacific coast from a little north of the Columbia River to the Colorado, extending eastward to the Sierra Nevada, while of another genus (*Cathartes*) one species ranges from the Strait of Magellan to the Saskatchewan, but a second hardly strays further northward than North Carolina, and does not occur on the Pacific coast of the United States; the Turkeys (*Meleagridæ*), found only to the eastward of the Rocky Mountains, and now extinct in most of the settled districts of Pennsylvania, New England, and Canada; the Wood-Ibises (*Tantalidæ*), belonging to the southern country from the Colorado eastward, and so far to the north as the State of Ohio and the Carolinas; the Spoonbills (*Plataleidæ*), with apparently much the same range as the last, but more limited towards the north, being of only accidental occurrence on the Lower Mississippi and in the Carolinas; the Courlans (*Aramidæ*), frequenting in this region only the shores of the Gulf of Mexico and the coast of Florida; the Flamingoes (*Phœnicopteridæ*), with haunts nearly as much confined, though occasionally reaching South Carolina; the Pelicans (*Pelecanidæ*), having one species abundant in the Western and only by chance occurring in the Middle and Eastern states, while a second is of strictly marine habit, and is found on the coast of California, and in the Gulf of Mexico and the shoals of Florida. The single representative of the Darters (*Plotidæ*) in summer reaches North Carolina and Illinois, but that of the Frigate-birds (*Fregatidæ*) is confined to the shores of the great Gulf, while that of the Tropic-birds (*Phaetontidæ*) not only haunts the same waters but also finds a nursery in the Bermudas; the species of Divers (*Colymbidæ*) breed only in the north—Halifax, in lat. 45° N., being perhaps their most southern limit of reproduction; while, finally, the Auks (*Alcidæ*), Sea-birds of Northern range, exhibit a most remarkable development of genera, species, and individuals on the rocky cliffs and islets which rise from the North Pacific.

Alaska.

Reference has already been made to the peculiarity of the avifauna of Alaska—Russian America, as it was formerly called,—and its character needs brief notice. The list of Birds observed in this territory, as given by Messrs Dall and Bannister,[3] seems after due revision to number 210 species. Of these 96 are Land-birds, belonging to 63 genera, whereof 20 at the outside are peculiarly American, while of the remaining 43, which are common to the Nearctic and Palæarctic Regions, 3 are found nowhere else in the New World but in Alaska, and their occurrence there does not preclude us from setting them down as being emphatically Palæarctic forms. Two of them are actually represented by species common throughout the greater part of Asia and Europe, as is the case with *Budytes flavus*, a Yellow Wagtail, and *Phylloscopus borealis*, a Willow-Wren, while the third is a peculiar species of Bullfinch, *Pyrrhula cassini*. Of the whole 96 species of Land-birds, 23, or *nearly one-fourth*, are common to the two Regions. The Water-birds, amounting to 115 species, are referable to 63 genera, of which only 4 (all belonging to *Scolopacidæ*) are

[1] *Bulletin of the Museum of Comparative Zoölogy at Harvard College*, vol. ii. pp. 387–407.

[2] *Memoirs of the Boston Society of Natural History*, vol. i. pp. 448–526, and *Bulletin of the Museum of Comparative Zoölogy*, vol. iii. pp. 113–183.

[3] *Transactions of the Chicago Academy of Sciences*, vol. i. pp. 267–310.

peculiarly Nearctic, though of the species 58 are truly American against 52 common to both Regions, one of these last, however, not having been found elsewhere in the New World, while the home of 5 seems doubtful. These numbers will show the great influence of Palæarctic forms on Alaska, and it only remains to be said that some of the ordinary summer-migrants thither would seem to arrive there from Asia, as the Wagtail and Willow-Wren just mentioned, to which should possibly be added the Wheatear (*Saxicola œnanthe*), for though that species is known as a regular annual visitant to Greenland and Labrador (where it breeds), and almost annually appears as a straggler on the eastern coast of the United States, the flocks which throng the stony hill-tops of Alaska in spring are not likely to have performed a north-west passage from Europe, and indeed it is stated that specimens from Norton Sound differ considerably in dimensions from those obtained in Greenland. All these Birds are unseen in British Columbia, and as all are migratory, the inference that they make some part of Asia their winter-quarters is almost irresistible.

After all, perhaps there is nothing very surprising in this, when we consider the narrowness of the channel[1] by which in these longitudes the New World is divided from the Old, and it would seem that it is almost within the confines of the Arctic circle that, apart from circumpolar species, the connection of the faunas of the two continents is closest.

Aleutian and Prybilov Islands.

At any rate, the Aleutian Islands, though they look like stepping-stones from the one to the other, do not appear to be used as a route of communication; for Mr Dall calls especial attention to the fact that no intrusion of Asiatic forms occurs towards the western end of the chain, while observing that its avifauna beyond Oonalaska is reinforced by several Arctic species not possessed by more eastern islands.[2]

Northward of the Aleutians lies a little volcanic group known as the Prybilov Islands, whose coasts are frequently encumbered by ice, and there only 40 species of Birds have as yet been found, while those which breed are about 12 in number, and among them a Sandpiper (*Tringa ptilocnemis*), apparently peculiar to St Paul's Island, the largest of the group. Only one of the characteristically Palæarctic forms, and this also a Water-bird (*Limosa uropygialis*), which appear but in Alaska, seems there to occur—a fact which points yet again to the more northern connection of the two continents by way of Cape Prince-of-Wales and the East Cape (Vostochni) of Asia.

Bermudas.

We have next to turn to another group of islands, situated in a different ocean, and in formation very unlike that last considered. These are the Bermudas, a cluster of low coral-reefs rising from the Atlantic, about 600 miles from Cape Hatteras, the nearest point on the eastern coast of North America. They possess but few Land-birds, and not a single peculiar species, yet they play by no means an unimportant part as a resting-station to the flocks of migrants as they retreat southward from their northern homes in Labrador and Greenland, and, though less often, on their northward journey in spring. Only about 6 Land-birds are resident, and about as many Water-birds are known to breed there; but the number of stragglers is large, and includes two or three of undoubtedly European extraction.

Greenland.

Greenland is the last portion of the Nearctic Region to which we shall especially invite attention, and there though the character of the avifauna is certainly that of the New World, yet that of the Old is very influential. Out of the 45 genera to which the feathered inhabitants of Greenland belong, none are peculiar to the Palæarctic Region, while 2—*Zonotrichia*, one of the *Emberizidæ*, and *Rhodostethia*, one of the *Laridæ*—are peculiar to the Nearctic. If we take the species, we find that of the 63 inhabitants, those peculiar to the New World amount to 11, while those not elsewhere dwelling out of the Old are only 5. But, on the other hand, the Sea-Eagle (*Haliaetus*), the Ringed Plover (*Ægialitis*), and the Snipe (*Scolopax*) which breed in Greenland are those of Europe instead of their American congeners; and the Wheatear (*Saxicola*), the Sanderling (*Calidris*), the Knot (*Tringa canutus*), and the Bernacle-Goose (*Bernicla leucopsis*) would appear to cross the Atlantic from the east, while 43 out of the 63 inhabitant species are every bit as much Palæarctic as Nearctic; and 2 more, the Ptarmigan (*Lagopus rupestris*) and Barrow's Duck (*Clangula islandica*) breed abundantly in Iceland. Following the western coast-line (for of the eastern we know little) to the Arctic circle,[3] we find the proportion of forms which are common to the Palæarctic Region increase, until in lat. 75° N. or thereabouts, there are (so far as our means of information will allow us to judge) no species of Birds which have not been known to occur, and only about 5 which have not been known to breed, in the Old World.

Similarity of Nearctic and Palæarctic fauna.

It has been already stated that 128 out of the 330 Nearctic genera, or more than one-third, are common also to the Palæarctic Region. This will serve to shew the great similarity of the two; and if we investigate the species, the similarity is still to a great extent borne out. Taking the number of Nearctic species at 700 (which is perhaps an exaggeration), and that of the Palæarctic at 850 (which is certainly under the mark), we find that, exclusive of stragglers, there are about 100 common to the two Regions. Nearly 20 more are Palæarctic but occasionally occur in America, and about 50 are Nearctic which from time to time stray to Europe or Asia.[4] But this is not the only ground of the resemblance. Of many genera the species found in the New World are represented in the Old by species which often no one but an expert can distinguish. Of such representative or parallel species, somewhere about 80 might be enumerated; and thus the relation of the two regions may be concisely stated:—

Species inhabiting the Nearctic Region....	(say) 700.	Species inhabiting the Palæarctic Region..	(say) 850.
Species of one Region represented by closely allied forms in the other.........	(say) 80.	Species identical in both Regions........	(say) 100.
Palæarctic species occasionally found in the Nearctic Region	(say) 20.	Nearctic species occasionally found in the Palæarctic Region..	(say) 50.

PALÆARCTIC REGION. Boundaries.

IV. THE PALÆARCTIC REGION begins with the Atlantic Islands (the Azores, Canaries, and Madeiras) and includes that portion of North-west Africa which was formerly known as the Barbary States, the whole of Europe and its islands—from Iceland and Spitsbergen to those of the Mediterranean—Asia Minor, Palestine, Persia, Afghanistan, and all the rest of the Asiatic continent lying to the northward of the Himalaya Mountains and of a line drawn as though it was a prolongation of that range to the east-

[1] Behring's Strait is said also to be very shallow, which fact is suggestive as to a still greater interchange of animal life in past ages.

[2] *Proceedings of the Californian Academy of Sciences*, 14th March 1874.

[3] People are apt to forget that Cape Farewell, the most southerly point of Greenland, lies in the latitude which cuts the Shetlands and passes far to the south of Iceland; and a large portion of the country though undoubtedly exposed in the highest degree to the rigours of an Arctic climate, is situated outside the Arctic circle.

[4] Professor Baird, in the essay before cited, has reasonably accounted for this disproportionate reciprocity between Europe and America; but perhaps something more than he has allowed must be set down to the comparative want of records in the new country, where observers and amateur collectors have until lately been scarce. This want is, however, being speedily supplied by the numerous students of out-of-doors ornithology, who are everywhere springing up throughout the United States.

ward somewhere between lat. 30° and 35° N. till it meets the Pacific Ocean, besides Japan and the Kurile Islands. The propriety of comprehending this enormous tract in one Zoological Region was first shown by Mr Sclater, in the paper to which reference has before been made,[1] and as regards the distribution of most classes of animals there have been few to doubt that it is an extremely natural one. Not indeed altogether so homogeneous as the Nearctic Region, it presents however even at its extreme points no very striking difference between the bulk of its Birds. Though Japan is far removed from Western Europe, and though a few generic forms and still fewer families inhabit the one without also frequenting the other, yet there is a most astonishing similarity in a large portion of their respective Birds. In some cases the closest examination has failed to detect any distinction that may be called specific between the members of their avifauna; but in most it is possible to discover just sufficient difference to warrant a separation of the subjects. Nevertheless it is clear that in Japan we have as it were a repetition of some of our most familiar species—the Redbreast and the Hedge-Sparrow for example—slightly modified in plumage or otherwise so as to furnish instances of the most accurate representation.

Homogeneity of its fauna.

Its limits generally definite.

The limits of the western portion of the Region are definite enough, for except in its African province it is girt by the sea, but even there we find a boundary hardly inferior to a coast-line in the precision with which it may be recognized and in the influence it exerts. This is the Great Desert, commonly known as the Sahara, which, though yearly crossed by innumerable multitudes of many of the more migratory species, just as the sea itself is traversed by them, acts as a complete barrier to the less migratory and to the residents, cutting off the denizens of Morocco, Algeria, and Tunis from the rest of the continent to which they are geographically attached. Further to the eastward, however, the limits of the Region are if in any way marked at least but little known, though indications are not wanting to show that the avifauna of Tripoli is rather Ethiopian than Palæarctic in its character. When we reach Egypt we have a state of things which may be compared to that debatable land in Central America wherein the Neotropical and Nearctic avifaunas meet but hardly mingle. During winter the bird-population of the Nile-valley is formed almost exclusively of the hordes of European migrants of nearly all Orders and families which there seek refuge. When spring returns these begin to troop across the Mediterranean, and their place is taken by the indigenous Birds of Egypt which had been either reduced to comparative insignificance by, or actually thrust out before, the northern invaders. The seaboard of Palestine, and even its interior, until the western limits of the Jordan-basin are touched, are on the contrary almost purely Palæarctic, but the depressed valley of the Ghor, part of which is sunk about 1300 feet below the level of the Mediterranean, seems to be an outlier of the Ethiopian Region, and though the scanty avifauna of the Mountains of Moab may possess a northern phase, the desert, with its characteristic, and in the main Ethiopian, forms of animal-life almost immediately succeeds, and it is not until the fertile plains of Mesopotamia are approached or attained that we can feel assured we have again entered the Palæarctic area, which may be considered to reach the head of the Persian Gulf. Coasting this inlet on its eastern side we have a fauna the character of which it is as yet impossible to declare, and this difficulty becomes greater still when we emerge into the Indian Ocean. It seems most probable that Beloochistan belongs to the Palæarctic Region, but if not then the line of demarcation must run inland and so continue between that land and Afghanistan till, ascending the right bank of the valley of the Indus, it turns the shoulder of the Great Snowy Range and thence proceeds in the direction already traced parallel to the southern frontier of Thibet, and across the intervening portion of the Chinese Empire, once more to the ocean. Arrived here the remaining limits of the Region are as well marked by the coast-line as they were in Europe. They extend to Kamchatka, and rounding the furthest verge of Asia, within the Arctic circle, they return by the north coast of Siberia till the confines of Europe are again reached.

Subdivisions.

To separate this vast area into subsidiary districts according to the zoological properties of each is perhaps a less easy task than is the same operation with regard to the Nearctic Region, and, as in that case, the mapping-out of the whole into Subregions is almost impossible except it be done arbitrarily. Nevertheless the attempt must be made, and, though in the Asiatic half considerable assistance is to be derived from a careful essay by Mr Elwes,[2] respecting the European moiety much doubt may be reasonably entertained.

The very fulness of the information which we possess as to the ornis of some countries of Europe makes the scarcity of it in respect to others all the more conspicuous, and renders any really comprehensive view of the whole all the more difficult. Grounds are not wanting at first sight in favour of a longitudinal or approximately longitudinal division of this quarter of the globe, in which case the line of demarcation might be taken to run up the Adriatic Sea, and starting from the neighbourhood of Trieste, to cross the Carnic Alps, descend the valley of the Inn till it falls into the Danube, and thence follow the angular mountain-frontier of Bohemia as far as the head-waters of the Niesse, along which it would proceed to their junction with the Oder, and so to the Baltic a little to the westward of Stettin. Thence it might be continued northward between Œland and Gottland up the Gulf of Bothnia to the confines of Sweden and Finland, where cutting the Scandinavian peninsula to the westward of the Lower Torneå and its affluent the Muonio it would strike the shores of the Arctic Ocean perhaps on the Lyngen Fjord. Though undoubtedly most species of Birds are common to both sides of this imaginary line, yet it would be found to divide the breeding-range of a few which are very characteristic of the east and west of Europe respectively. But on further consideration it would seem that though such a division as has just been suggested may be convenient if not natural for the countries lying north of the Mediterranean basin, those, such as the three principal peninsulas which project into the great inland sea, together with the portion of North Africa which was at one time known as Mauritania, form a group which have much in common, and collectively differ more from the countries lying further to the north than the two (Eastern and Western) divisions of Central and Northern Europe, just suggested, do from one another. Accordingly it seems best to adopt primarily a latitudinal division of the Western part of the Palæarctic Region. This done we should have as our first Subregion all Europe north of the Pyrenees, the Alps, the Balkan, the Black Sea, and the Caucasus, and since it would thus comprehend by far the greater portion of this quarter of the globe, we may not inappropriately call it the "European" Subregion, further subdividing it if we think fit into a Western and an Eastern Province, according to the boundary above traced—the eastern boundary of the last being indeed very uncertain, though perhaps to

Limits of Subregions.

[1] *Journal of the Proceedings of the Linnean Society, Zoology,* vol. ii. pp. 134–138.

[2] *Proceedings of the Zoological Society,* 1873, p. 615.

be limited by the Ural Mountains and the River of the same name. Next we should have the Subregion to which we may most properly affix the name of "Mediterranean," comprehending the portion of North Africa already indicated, the Iberian and Italian peninsulas, as well as Turkey in Europe and the Peloponnesus, but we must extend it far to the eastward through Asia Minor and Persia until it touches the Indian Region. The lofty range of the Caucasus would divide it from the European Subregion between the Black Sea and the Caspian; beyond the latter, however, we cannot do more than guess that the desert of the Tekko Turcomans and the mountains of Cabool would form its northern boundary. Then stretching from the eastern shores of the Caspian in a wide belt, but how wide is a matter of the greatest uncertainty, comes the third Subregion, which we may call the "Mongolian"—marching with the Mediterranean Subregion till the Hindoo Koosh is reached, and thence coincident with the southern borders of the Region towards the Yellow Sea—possibly following the course of the Yangstzekiang. To this Subregion also would belong the greater part if not the whole of Japan. Northward again we have the great "Siberian" Subregion, but materials for any attempt to shew whether its southern boundary is capable of being laid down are absolutely wanting. Even on the seaboard it is at present impossible to say whether it is in Manchuria that one Subregion passes into the other, or whether first the Stannovoi and further inland the Altai Mountains mark their respective limits.

General characteristics.

Having thus indicated the component parts of the whole area, it is time to say somewhat of its avifaunal characters. Like the Nearctic the Palæarctic Region seems to produce but a single peculiar family of Birds—the *Panuridæ*, the type of which is the beautiful species known to Englishmen as the Bearded Titmouse (*Panurus biarmicus*)—and this is a family which has not been long or very generally recognized. Its members, however, are found stationed at intervals from the western to the eastern extremity, and every attempt to refer them to other groups of Birds has proved unsatisfactory—for the different genera (about the number of which there is much doubt) have often been widely scattered by systematists, one being placed at times with the Titmouse-family (*Paridæ*), at times with the Buntings (*Emberizidæ*), another relegated to the Finches (*Fringillidæ*), and a third or even more to the so-called "Babblers" (*Timeliidæ*). The entire number of Palæarctic families, computing them as we have already done those of other Regions, is about 67, not counting 1 other (*Nectariniidæ*) of which a single species is peculiar to the valley of the Ghor, and that of the genera 323, about which there can be little doubt, or if any exist it may be that the number is understated. Of these as we have above mentioned 128 are common to the Nearctic Region. Species of 51 more seem to occur as true natives both in the Ethiopian and Indian Regions, of which 4 genera belong to *Sylviidæ*, 1 each to *Timeliidæ*, *Ixidæ*, and *Oriolidæ*, 2 to *Muscicapidæ*, 1 to *Laniidæ*, 2 to *Motacillidæ*, 1 to *Dicæidæ*, 2 to *Fringillidæ*, 1 to *Emberizidæ*, 3 to *Alaudidæ*, 1 to *Cuculidæ*, 2 to *Coraciidæ*, 1 to *Meropidæ*, *Upupidæ*, *Caprimulgidæ*, and *Cypselidæ* respectively, 4 to *Vulturidæ*, 6 to *Falconidæ*, 1 to each of *Strigidæ*, *Columbidæ*, and *Pterocleidæ*, 3 to *Tetraonidæ*, 1 to *Turnicidæ*, 2 to *Otididæ* and *Charadriidæ*, and 1 to each of *Glareolidæ*, *Cursoriidæ*, *Laridæ*, and *Anatidæ*. Besides these 18 appear to be common to the Ethiopian without being found in the Indian Region, and no fewer than 71 to the Indian without being found in the Ethiopian. Of the former 1 is referable to *Turdidæ*, 3 to *Sylviidæ*, 1 to each of *Timeliidæ*, *Muscicapidæ*, *Laniidæ*, and *Motacillidæ*, 3 to *Fringillidæ*, 1 to *Emberizidæ* and *Sturnidæ* respectively, 3 to *Alaudidæ*, and 1 to each of *Gruidæ* and *Ciconiidæ*.

Relations to other regions.

Of the latter, 2 genera belong to *Turdidæ*, 17 to *Sylviidæ*, 4 to *Timeliidæ*, 1 to each of *Troglodytidæ* and *Certhiidæ*, 3 to *Liotrichidæ*, 1 to *Paridæ* and *Ixidæ* respectively, 4 to *Muscicapidæ*, 1 to each of *Motacillidæ* and *Hirundinidæ*, 3 to *Fringillidæ*, 4 to *Sturnidæ*, 3 to *Corvidæ*, 1 to *Pittidæ*, 2 to *Picidæ*, 1 to *Jyngidæ* and *Cuculidæ* respectively, 2 to *Alcedinidæ*, 1 to *Vulturidæ*, 3 to *Strigidæ*, 2 to each of *Columbidæ*, and *Tetraonidæ*, 5 to *Phasianidæ*, 1 to *Otididæ*, 3 to *Scolopacidæ*, and 1 to *Anatidæ*. To compare the Palæarctic genera with those of the Australian and Neotropical Regions would be simply a waste of time, for the points of resemblance are extremely few, and such as they are they lead to nothing. It will therefore be seen from the above that next to the Nearctic Region, the Palæarctic has a much greater affinity to the Indian than to any other, a fact which need not surprise us when we consider the great extent of their contact.

Having shewn this much we have next to deal with the peculiarities of the Region under our view. At the lowest computation 37 genera seem to be peculiar to it, though it is certain that species of several are regularly wont to wander beyond its limits in winter seeking a southern climate there to avoid the distress they would suffer in that of their birth. Of these genera 3 are to be apportioned to the Warblers, *Sylviidæ*; probably 2 to the Babblers, *Timeliidæ*; at least 3 or perhaps 4 to the *Panuridæ*; 1 to each of *Paridæ* and *Ixidæ*; 2 to the Flycatchers, *Muscicapidæ*; 6 to the Finches, *Fringillidæ*; 1 to the Buntings, *Emberizidæ*, Starlings, *Sturnidæ*, Crows, *Corvidæ*, Woodpeckers, *Picidæ*, and the Sand-Grouse, *Pterocleidæ*, respectively; 2 to each of the Grouse, *Tetraonidæ*, and Pheasants, *Phasianidæ*; 1 to the Ducks, *Anatidæ*, and Cranes, *Gruidæ*, respectively; 2 to the Plovers, *Charadriidæ*; and 5[1] to the Snipes, *Scolopacidæ*.

European Subregion.

The European Subregion does not seem to possess a single genus which can be accounted absolutely peculiar to it, but it has two genera, each containing but one species —*Mergulus*, one of the *Alcidæ*, and *Pagophila*, belonging to the *Laridæ*—which do not appear to be elsewhere found in the Palæarctic Region though both inhabit the most northern parts of the Nearctic. *Muscicapa* as now restricted[2] almost fulfils the conditions of peculiarity, but one species has been said to breed, though in small numbers, in Palestine.

Mediterranean Subregion.

The Mediterranean Subregion appears to have peculiar to it 4 genera of *Sylviidæ*, and 1 of *Laridæ*; but some 23 more belong to it and to no other part of the Region, though having a wider range outside of the latter. Of these there are 8 common to both the Ethiopian and Indian Regions, namely, 1 of *Vulturidæ*, 3 of *Falconidæ*, and 1 of *Tetraonidæ*, *Anatidæ*, *Glareolidæ*, and *Cursoriidæ* respectively. Confined to the same Subregion and the Ethiopian Region are 11, to wit, 1 of *Turdidæ*, 1 of *Sylviidæ*, 1 of *Timeliidæ*, 1 of *Laniidæ*, 2 of *Fringillidæ*, 1 of *Emberizidæ*, 1 of *Sturnidæ*, 1 of *Alaudidæ*, 1 of *Vulturidæ*, and 1 of *Charadriidæ*; while having the like relation to the Indian Region are 2—1 belonging to *Cuculidæ* and 1 to *Otididæ*. Of the family last named another genus (*Eupodotis*), which only just makes its appearance in Morocco, ranges over Africa, India, and Australia; and a genus of *Anatidæ* (*Erismatura*) is represented in America and Australia as well as in Africa.

The Atlantic Islands, which must be regarded as outliers

[1] One of these last has for a wonder received no name from systematists, but its generic separation seems on several grounds expedient. It is that which would have for its type the *Tringa platyrhyncha* of Temminck.

[2] That is excluding *Butalis*, *Erythrosterna*, and other kindred groups, as well as the purely Ethiopian forms which have been by some systematists attached to *Muscicapa* proper.

Peculiarities of Atlantic Islands.

of the Mediterranean Subregion, offer some peculiarities too remarkable to be here left unnoticed. First we have the Azores, the subject of an excellent monograph by Mr Frederick Godman,[1] in which is contained the result of his own investigations in that group, as well as those of his predecessors. There is a general tendency among Azorean Birds to vary more or less from their continental representatives, and this is especially shown by the former having always darker plumage and stronger bills and legs. In one instance the variation is so excessive that it fully justifies the establishment of a specific distinction. This is the case of the Bullfinch of the more eastern of these islands (*Pyrrhula murina*), the male of which, instead of the ruddy breast of its well-known congener (*P. vulgaris*), has that part of a sober mouse-colour. A similar sombre hue distinguishes the peculiar Chaffinch of the Canary Islands (*Fringilla teydea*), but to these islands as well as the Azores and Madeiras there belongs in common another Chaffinch (*F. tintillon*, which, though very nearly allied to that of Mauritania (*F. spodiogenia*), is perfectly recognizable, and not found elsewhere. Madeira has also its peculiar Golden-crested Wren (*Regulus maderensis*), and its peculiar Pigeon (*Columba trocaz*), while two allied forms of the latter (*C. laurivora* and *C. bollii*) are found only in the Canaries. Further on this subject we must not go; we can only state that Mr Godman has shown good reason for declaring that the avifauna of all these islands is the effect of colonization extending over a long period of years, and going on now.

Mongolian Subregion.

The Mongolian has the largest number of peculiar genera of any Palæarctic Subregion. In *Sylviidæ* there is 1, in *Timeliidæ* 2, in *Panuridæ* and *Iridæ* 1 each, in *Fringillidæ* 3, in *Sturnidæ* and *Pterocleidæ*[2] 1 respectively, in *Phasianidæ* 2, and in *Anatidæ* 1—or 13 in all; but, in common with the Indian Region, and that only, there are 10 of *Sylviidæ*, 4 of *Timeliidæ*, 1 of *Troglodytidæ*, 3 of *Liotrichidæ*, 1, rather doubtful in position, but possibly belonging to *Panuridæ*, 1 of *Iridæ*, 4 of *Muscicapidæ*, 1 of *Motacillidæ* and *Fringillidæ* respectively, 2 of *Sturnidæ*, 1 of *Picidæ*, 2 of *Strigidæ* and as many of *Columbidæ*, 1 of *Tetraonidæ*, 4 of *Phasianidæ*, and 1 generally referred to *Scolopacidæ*[3] —or 39 altogether. In common with the Ethiopian Region alone, the Mongolian Subregion has only 1 genus, and that belongs to *Motacillidæ;* but in common with both Ethiopian and Indian, though with these only, there are 1 of *Muscicapidæ* and 1 of *Laniidæ;* while 2 genera— 1 of *Fringillidæ* and 1 of *Scolopacidæ*—belong equally to the Nearctic fauna: 2 genera, members respectively of the *Dicæidæ* and *Pittidæ*, are common as well to the Ethiopian, Indian, and Australian Regions.

Siberian Subregion.

The Siberian Subregion seems to have but 1 genus peculiar. This is *Eurynorhynchus*, one of the *Scolopacidæ;* but as its breeding-quarters have never yet been discovered the matter must remain in doubt. One genus of *Laridæ* and 6 of *Alcidæ* are also common to the Nearctic Region, but do not inhabit any other Palæarctic Subregion.

Special cases of distribution.

It would extend the present article far beyond all reasonable bounds were we to dwell upon more than a few of the curiosities of distribution which have been revealed by the continuous observations of European ornithologists. There is no need to travel out of our own island to meet with some of the most remarkable among them, and we may take that of the Nightingale (*Daulias luscinia*) as an example. In England the western limit of the range of this incomparable songster seems to be formed by the valley of the Exe, which is only overstepped on rare occasions—Montagu having once heard it near Kingsbridge, while it is said to have been observed at Teignmouth and Barnstaple. But even in the east of Devonshire it is local and rare, as it also is in the north of Somersetshire, though plentiful in other parts of that county. Crossing the Bristol Channel it is said to be not uncommon at times near Cowbridge in Glamorganshire; but this seems to be an isolated spot, or at any rate there is no evidence of its being found elsewhere in Wales, or between that place and Tintern on the Wye, where it has been reported to be plentiful. Thence there is more or less good testimony of its occurrence in Herefordshire, Shropshire, Staffordshire, Derbyshire, and so on, to about 5 miles north of York, but not further. Along the line thus sketched out and immediately to the east and south of it, the appearance of the nightingale, even if regular, which may be doubted, is rare, and the bird exceedingly local; but in many parts of the midland, eastern, and southern counties it is abundant, and the woods, coppices, and gardens ring with that thrilling song which has been the theme of writers in all ages. There are many assertions of its occurrence in England further to the northward, but some of them rest on anonymous authority only, and all must be regarded with the greatest suspicion. Still more open to doubt are the statements which have been made as to its visits to Scotland, while in Ireland there is no pretence even of its appearance. No reasonable mode of accounting for the partial distribution of the Nightingale has hitherto been propounded: there is no peculiar kind of soil which it especially affects, or none, so far as we know, that it especially avoids; and the same may be said of its relations to the flora of this country. It is not so entirely *adscriptus glebæ* that it will not readily betake itself to new localities suited to its wants, when these have been formed within its natural limits, though they may be miles away from its ancient haunts. On the contrary, it is often one of the first birds to establish itself when a heath has been broken up, and plantations of trees thereon made have grown sufficiently to afford it the sheltering covert that it loves. This instance, taken from a bird whose habits have been so closely studied both in captivity and at large, and one which is so familiar, and in many places so numerous, that abundant opportunities are given for observing all that can be observed about it, shews how futile would be the expectation that in most cases we could at present, even if ever, satisfactorily account for the existing causes which limit the distribution of species. A vast majority of them, we know, have each its bounds, which virtually it cannot pass, and the case of the Nightingale in England, beyond the fact that its distribution is extremely well marked, and therefore has long attracted especial attention, has really nothing out of the common way in it.[4] In Europe, the neighbourhood of Copenhagen is the most northern point which our Nightingale is asserted to reach; but on the continent its range is less extended, and though abundant in Mecklenburg, it is not found in that part of Pomerania

Distribution of Nightingale.

[1] *Natural History of the Azores or Western Islands*, 8vo. London: 1870.

[2] The genus of this family here meant is *Syrrhaptes*, the Three-toed Sand-Grouse, one species of which (*S. paradoxus*) overran Europe in astounding numbers in 1863, and effected a temporary settlement both in Denmark and Holland.

[3] This is *Ibidorhynchus*, which, until some details of its osteology are known, can hardly be placed without risk of error.

[4] When the history of the earth shall be really well and minutely understood, it seems quite possible that as much light will be shed on this and other particular cases of the same kind by a knowledge of the various changes and displacements which sea and land have undergone as has already been done by the same means in regard to many of the general facts of distribution. The results of the labour of the geologist are doubtless just as necessary to, and closely connected with, the work of the biologist, as those of the investigation of the historian are to and with the efficiency of the statesman; while, in return, the researches of the biologist are, or ought to be, of the greatest service to the geologist. The history of the earth is for a long period of time that of its inhabitants.

which lies to the north of the river Peene, nor does it stretch so far to the eastward as Danzig. It occurs, however, sparingly on the Polish frontier, near Thorn, and is observed in Austria, Upper Hungary, and Gallizia. In Russia its distribution cannot be laid down with any degree of accuracy, but it does not reach the Governments near the Ural, though it is said to be plentiful in that of Kharkov, and it is known to visit the Crimea. Still further to the eastward it can be traced through Circassia, and as far as Kasbin in Persia. Southward of this imperfectly-drawn line it may be found as a winter-visitant even in Arabia, Nubia, and Abyssinia, as well as in Algeria, where it is reported as breeding, and it would seem to migrate thence so far as the Gold Coast. It is abundant in Spain and Portugal; but it is a stranger to Britanny, the western peninsula of France, just as it is to the western peninsula of England.[1]

Distribution of Kentish Plover.

One other example we may take, and this, though much less familiar, is equally instructive, as exhibiting some of the as yet unexplained peculiarities of distribution. It shall be from a Bird belonging to a very different Order from the last, having habits entirely dissimilar, and presenting in most ways a great contrast. The Kentish Plover (*Ægialitis cantiana*), first determined from specimens obtained on the coast of that English county whence it takes its specific name, has its breeding-place in Britain limited to the pebbly beach between Sandwich and Hastings, and in other parts of the British Islands only occurs as a chance straggler. Yet this bird has as wide a range elsewhere as almost any that could be named—breeding not only abundantly along the greater part of the coasts of the temperate and warmer portions of the Old World north of the Equator, but also occasionally in the interior, as at the base of the Caucasus and in the *chotts* of the North African plains; while during its migrations it wanders to the Malay Archipelago and South Africa, or even seems most likely to be specifically identical with a Plover which is found on the west coast of America, from California southward—though this last has been described as distinct under the name of *Æ. nivosa*.

European Islands.

Islands must always be a matter of the greatest interest to the student of Geographical Distribution, and we have already mentioned some peculiarities of those groups which belong to the Mediterranean Subregion of Europe. There are not many more here to be cited. Spitsbergen is supposed to have its peculiar species of Ptarmigan (*Lagapus hemileucurus*), though it is confessedly very nearly allied to the Rock-Ptarmigan (*L. rupestris*) which inhabits the Arctic portion of the American continent and islands, Greenland, and Iceland, but, except in the last-named country, does not occur in the Palæarctic Region. Iceland is also remarkable for being the headquarters of the noble Falcon (*Falco islandus*) which takes its name therefrom, though this bird also inhabits the southern districts of Greenland, to say nothing of other countries; and in Iceland alone of the western portion of the Region does the beautiful Harlequin-Duck (*Histrionicus torquatus*) breed. It is, however, known to inhabit North America and the eastern half of Siberia.

Distribution of Red Grouse.

Coming nearer home, we have a remarkable case of restricted distribution in the Red Grouse (*Lagopus scoticus*), found (and in certain districts, as every one knows, numerously), in each of the three kingdoms composing the British Islands as well as in the principality of Wales. The details of its local distribution, as of that of all other birds which breed in Great Britain, have been carefully and concisely given by Mr More,[2] and we do not propose to consider them here, but what is worthy of remark is that this particular species differs in no essential character save coloration from the Willow-Grouse (*L. albus*), which is an abundant bird throughout the whole of the northern parts of the Palæarctic Region from Norway to Kamchatka, and again throughout the same or even lower latitudes of the Nearctic Region from Alaska to Newfoundland. Its remains, as has before been said (page 731), have also been found in the south of France, associated with those of the Reindeer and Snowy Owl. It is not for us now to enter into any hypothetical discussion, but it is hard to resist drawing an inference that at a time, geologically speaking, not very recent, both these species of Grouse had a common ancestor, and that the severe winters to which it has for a long period been exposed have caused the Willow-Grouse to don the snowy garb that is characteristic of it and other species of the genus, the more so since we find it in its first plumage possessed of the coloured quills, which are precisely similar to those of the Red Grouse at the same age.

Other Peculiarities of British Birds.

Other instances there are in which British-born examples of species common to the continent are in a less degree distinguishable from those of neighbouring countries. The Coal-Titmouse of England is to be recognized from that of continental Europe (*Parus ater*), and accordingly by some ornithologists it is regarded as a distinct species (*P. britannicus*), but the scanty remnants of the ancient pine-forests of Scotland are inhabited by birds between which and European examples no difference can be established. The home-bred Bottle-Titmouse of Britain, too, has, from its darker coloration, been accorded specific rank, but then we occasionally find continental birds of this species (*Acredula caudata*) varying in this respect, and the specific validity of the British form (*A. rosea*) can hardly be with consistency maintained. Indeed, as a matter of fact, nearly all our smaller birds can be distinguished by an expert from their continental brethren, and this mainly through their duller or darker plumage. The difference is not so great by any means as obtains in the case of the birds of the Atlantic Islands above mentioned, but it most unquestionably exists to a greater or less degree; and it is curious that an analogous state of things is observable in regard to many of the birds of Japan, a country which is subject to many of the same climatic conditions as the British Islands. It will be for future investigators to ascertain the cause of this similarity, we here only record the fact; but another remarkable instance of the forms of the western portion of the region being repeated in the far east, is found in the range of the two kindred species of the beautiful genus *Cyanopica*—the Blue Magpie of Portugal and Spain (*C. cooki*) being replaced in Amoorland and Japan by a species (*C. cyanea*) so closely allied that some authorities refuse to acknowledge their distinctness, and yet throughout 130° of longitude no representative of either is found.

Ethiopian Region. Boundaries.

V. The Ethiopian Region, comprising the whole of the African continent, except the Barbary States, besides the Cape-Verd Islands and naturally those situated in the Gulf of Guinea, as well as Madagascar and the Mascarene group from Réunion (Bourbon) to the Seychelles, and the large island of Socotra, and crossing the Red Sea to Arabia, is sufficiently well marked out in a geographical point of view. The Ghor, or valley of the Jordan and the depressed basin of the Dead Sea, has been before mentioned as an outlier of this Region, the north-eastern part of which melts into the Palæarctic between Palestine and the Persian Gulf. There, and apparently there only, do its boundaries admit of no precise definition. Some zoogeographers seem inclined to extend its limits further to the eastward, through Beloochistan and even beyond the Indus; but though the desert-forms of a large portion of that tract of country are

[1] *Cf.* Yarrell, *British Birds*, ed. 4, vol i. pp. 315-318.
[2] *Ibis*, 1865, pp. 1-27, 119-142, 425-458.

undoubtedly closely allied to, if not identical with, the denizens of similar districts in Africa, yet it must be remarked that such forms should be regarded in much the same light as those which frequent wide seas, and that the determination of a desert-tract must therefore depend rather on the fauna which inhabits its islands—as we may term the oases which, whether plentifully or rarely, stud its surface —rather than on the fauna of the desolate space which surrounds these fertile and more favoured spots. Still, it is hardly to be denied that the influence of Ethiopian types is to be discovered in Sindh, Gujerat, and even further in the Indian peninsula. In the Ethiopian region we again find a number of the sub-class *Ratitæ* in the very specialized form *Struthio*—the Ostrich—and this ranges, or did range, from the immediate vicinity of the Cape of Good Hope to the confines of Algeria in the north-west, and to the banks of the Euphrates in the north-east.[1] It is even possible that within historic times it penetrated much further to the eastward and reached Sindh at least, and if this be so, the fact would lend colour to the proposed inclusion of that country within the Ethiopian region.[2] But without concerning ourselves with speculations of this kind, there is enough and to spare which marks the Region as one of the chief zoological portions of the globe, despite the mystery which still hangs over its interior and at present completely defies any attempt to trace the boundaries of its Subregions or provinces beyond a comparatively little distance from the coast.

General characteristics. So large a portion of the Ethiopian Region lies between the tropics that no surprise need be expressed at the richness of its fauna relatively to that of the last two Regions we have considered. Between 50 and 60 families of land-birds alone are found within its limits, and of them at least 8—*Buphagidæ*, *Eurycerotidæ*, *Musophagidæ*, *Irrisoridæ*, *Leptosomidæ*, *Coliidæ*, *Serpentariidæ*, and *Struthionidæ*—are peculiar; but it is singular that of them only 2 belong to the Order *Passeres*, a proportion which is not maintained in any other tropical Region. The number of peculiar genera is too great for them to be named here; some of the most remarkable, however, especially of those peculiar to one of its Subregions, whose Bird-life has been differentiated to a degree that is very extraordinary, will presently be mentioned.

Limits of Subregions. The subdivision of the Ethiopian Region is perhaps accomplished with less difficulty than in the case of the more temperate tracts with which we have lately had to do. Bounded on the north by the Mediterranean Subregion of the Palæarctic Region, we have a Subregion extending from the Cape-Verd Islands on the one side of the continent to Socotra on the other; and with this we must comprehend all the Asiatic territory, whatever be its limits, which is, for zoogeographical purposes, to be annexed to the Ethiopian Region. On the West Coast of Africa the southern frontier of this Subregion, which we may call the "Libyan,"[3] seems to lie a little to the northward of lat. 10° N.; but, owing to the unexplored state of the country, we quickly lose trace of its confines. We may perhaps presume that they more or less follow that parallel to somewhere about long. 15° E., and then trend in a south-easterly direction. On the East Coast the frontier of the Libyan Subregion extends from near Cape Guardafui in a south-westerly direction towards the system of the Great Lakes, all the waters flowing to which it may be held to include; and is then succeeded by the "Mosambican" Subregion, which continues perhaps to Sofala. Beginning on the West Coast, where the Libyan Subregion stops, we have another Subregion, the "Guinean," comprising the seaboard from Sierra Leone to somewhere about Angola; but as to how far inland this penetrates we are absolutely without information. The rest of continental Africa forms what may be called the "Caffrarian"[4] Subregion, while Madagascar, the Comoros, and the widely-scattered Mascarene Islands, constitute a fifth Subregion, the most distinct and remarkable of all, and for this we may most reasonably use the name "Madagascarian."

Libyan Subregion. (1.) *The Libyan Subregion*, the first we have separated, may perhaps be broken up into four provinces—the Arabian, Egyptian, Abyssinian, and the Gambian; but it must not be expected that all their respective boundaries can be distinctly drawn—those of the first excepted, which, however, seems to be the one that has precisely the fewest positive characteristics, and the propriety of its recognition, except on purely geographical grounds, is most questionable.

Arabian province. We may doubt whether it has more than half-a-dozen peculiar species; but then we know next to nothing of the zoology of any part of Arabia, save the Peninsula of Sinai and the desert of the Tîh. As before mentioned the Ostrich occurs here, but its present northern or eastern limits are indeterminate; we know, however, that within recent years it has been killed in the desert of Belka, just on the other side of the Dead Sea. The species which seem to be peculiar to the Jordan basin are—*Crateropus chalybæus*, *Nectarinia osea*, *Passer moabiticus*, *Amydrus tristrami* and *Caprimulgus tamaricis*, the last but one of which in its name commemorates Canon Tristram, the naturalist to whom we owe most of our information as to the fauna of this singular district.

Egyptian province. The Egyptian province, so far as regards the valley of the Lower Nile, is remarkable for being, as already stated, overrun by migrants from Europe during the winter, and since it is chiefly from the observations of travellers at this season that most of our knowledge is derived, it is perhaps not very wonderful that many zoogeographers are inclined to include this district within the Palæarctic Region. The number of species which occur in Egypt and Nubia, as given by Captain Shelley,[5] is 352, but many of them he says are of doubtful occurrence. Of these more than 230 are natives of the Palæarctic Region; but only between 50 and 60, or about one quarter of them, remain to breed in Egypt, and of this number a considerable proportion do not breed in Europe, but only in the Barbary States. The extra-Palæarctic character of the Egyptian ornis seems to be thus fully established.

Abyssinian province. Respecting the Abyssinian province very full particulars are included in the lately-completed work of Dr von Heuglin;[6] but for our purpose it is not easy thence to ascertain the precise features of its avifauna, since he has not discriminated between it and the Egyptian. North-east Africa, according to him, has about 950 species of Birds, of which he reckons about 325 as migrants from Europe or Western Asia—that is to say, from the Palæarctic Region. Of these 113 breed in that Region, as well as in North-eastern Africa; 294 have been observed in the Bar-

[1] Xenophon, *Anabasis*, I. v. 2.

[2] For all that can be said as to the supposed former extent of the Ostrich's range in Asia, and, indeed, for the best account of this Bird that has ever been published, see Finsch and Hartlaub, *Vögel Ost-Afrikas* (pp. 597-607), forming the fourth volume of Von der Decken's *Reise in Ost-Afrika* (Leipzig und Heidelberg: 1870). Fossil remains of *Struthio* have been indubitably recognized from the Sivalik hills in India.

[3] In using this name the writer follows Blyth (*Nature*, iii. p. 428, March 30, 1871). Mr Sharpe, whose kind assistance in preparing this portion of the present treatise the author gratefully acknowledges, has proposed to call this Subregion the "Abyssinian," from its leading characteristics being most evident in that country, but that name would seem to be better applied to a province, and accordingly, here a more general designation appears preferable.

[4] Again following Blyth (*loc. cit.*)

[6] *Ornithologie Nordost-Afrika's*. Cassel: 1859-75.

bary States; 438 are common to the West Coast, but whether to the Guinean Subregion, presently to be treated, or only to the Gambian province of the Libyan, is not stated; 318 are common to South Africa or the Caffrarian Subregion, and 253 only to the Mosambican; while 215 are peculiar to the district to which his work especially relates; the last statement being the most important for our present use, since it cannot be doubted that nearly all these 215 species are peculiar to the Abyssinian province, which may be taken as extending from about the southern frontier of Dongola to the Victoria Nyanza, and from the Kosanga River (long. 27° E.) to Cape Guardafui. One of the most wonderful forms of Birds peculiar to this province is the gigantic Whale-headed Stork, *Balæniceps rex*. Of Socotra we know far too little to determine its provincial affinity.

Gambian province. Of the Gambian province we cannot say much, through want of materials to convey any definite notion of its character; and we are only able to confirm the general belief that it has a good deal in common with the Abyssinian, next to be mentioned, for without lists carefully drawn up by those who have a special knowledge of the avifauna of a country, or the power to compile such for oneself, which in this case the present writer does not possess, any attempt at a critical examination of its details would be rather misleading than otherwise. The province probably lies between lat. 18° and lat. 10° N., but whether it preserves those limits in the interior, whether it passes directly into the Abyssinian, or whether another province intervenes, are questions that cannot be now decided. It would seem to have in common with the East Coast several very characteristic species, of which *Buphaga africana*, *Vidua paradisea*, *Parus leucopterus*, *Corythornis cyanostigma*, *Coracias nævia*, and *Toccus nasutus*, with *T. erythrorhynchus*, may be mentioned.

Cape-Verd Islands. To the Gambian province belong the Cape-Verd Islands, which, out of 17 or 18 Land-birds enumerated by Dr H. Dohrn (*Journ. für Ornith.* 1871, pp. 1-10), seem to have 2 peculiar species—a Sparrow (*Fringillidæ*) and an aquatic Warbler (*Sylviidæ*).

Guinean Subregion. (2.) *The Guinean Subregion* is the next to be treated, and occupies what is commonly spoken of as the "West Coast" of Africa, extending from Sierra Leone to the south of Congo, while its breadth is a matter of the greatest uncertainty. Hitherto no catalogue even of its birds has been published, for the work of Dr Hartlaub[1] comprehends also those of the Gambian province of the Libyan Subregion, while, admirably executed as it was at the time of its appearance, so much has since been done by collectors in this part of Africa, and by those who in Europe have examined their collections (especially Professor Barboza du Bocage and Mr Sharpe), that its results must be regarded as out of date. Yet no good, and much harm, would follow from any attempt to generalize on the facts thus recorded, at various times and in various publications, except it were made by one especially acquainted with African ornithology; and we must therefore, perforce, leave the continental portion of this Subregion without trying to exhibit its particular characteristics. **Its islands.** Respecting the islands belonging to it, however, somewhat may be advanced with more confidence. The chief of these are four in number—Fernando Po, Prince's Island, that of St Thomas, and Annobon. The first, lying in the Bight of Biafra, was once believed to possess a very peculiar avifauna; but one by one, all, or nearly all, of the supposed peculiar species have been found on the mainland, until it seems likely to have none whatever. Prince's Island, situated outside the Bight, but still lying within the Gulf of Guinea, has been said to possess 1 peculiar genus, *Cuphopterus* (of perhaps uncertain affinity, though it has been referred to the *Timeliidæ*), comprising a single species, (but this has since been sent from the Gaboon) and 6 other species—1 each of *Dicæidæ* and *Hirundinidæ*, and 2 of *Ploceidæ* and *Columbidæ* respectively. A curious assertion has been made with regard to this island, namely, that it is not inhabited by any Diurnal Bird-of-prey, all such being, it is said, driven off by the Grey Parrots (*Psittacus erithacus*) which there abound. The island of St Thomas, lying nearly or just under the equator, also has 6 peculiar species, belonging respectively to the *Turdidæ*, *Dicæidæ*, *Oriolidæ*, *Ploceidæ*, *Columbidæ*, and *Strigidæ*; while another species of the family last mentioned is common to this and Prince's Island, but seems to be found nowhere else. Of Annobon we know nothing.

Caffrarian Subregion. (3.) *The Caffrarian Subregion* has its inland boundaries as ill-defined as either of the preceding, yet its distinctive features are much more marked—a fact which is doubtless to some extent explained by so great a portion of it lying without the tropic. Though this part of Africa has perhaps received the closest attention from ornithologists, the several labours in various districts of the Subregion of Levaillant and Jules Verreaux, Andersson and Andrew Smith, Mr Layard and Mr Ayres, assisted at home by Sundevall and Mr Gurney, all require digesting before their bearings upon the subject of geographical distribution can be fully comprehended; and, as in the cases previously mentioned, the careful collation and comparison of different lists can only be usefully accomplished by one who has a special knowledge of the objects treated by those writers, and any attempt to attain this end by an expert would be dangerous. Only one island can be with certainty affiliated to this Subregion, and that is St Helena, **St. Helena.** where the indigenous Land-birds, if any there were, have probably been extirpated with most of its original and peculiar flora. Yet, curious as it may be, it seems to be a fact that this isolated spot possesses a peculiar Water-bird, albeit it is of a group which greatly affects dry places. This is a small Ringed Plover (*Ægialitis sanctæ-helenæ*), and, though belonging to a genus the members of which are remarkable for very wide distribution, it is not known to have occurred off the island. Tristan da Cunha, commonly assigned to the Ethiopian Region, and therefore to this Subregion, seems, from reasons before stated, to have at least as much affinity to the Neotropical, and Ascension appears to have no indigenous Land-birds whatever, so that its appropriation must remain in doubt.

Mosambican Subregion. (4.) *The Mosambican Subregion* next follows, and its relations to the Abyssinian the numbers already quoted from Dr von Heuglin will have shewn, but these must be taken with caution, since the limits of the Subregion are so indefinite. Whether we should comprehend in it the whole of the country drained by the Zambesi and its tributaries seems to be very uncertain; but, judging from the collections he has received, Mr Sharpe is now inclined to think that this part has more affinity to South Africa. The general uniformity of distribution which obtains among the Birds of all the tropical portion of the Region, especially noticed by Dr Kirk in writing on those of Zambesia (*Ibis*, 1864, p. 307), requires much fuller geographical details than are at present available to entitle us to form any very decided opinion, though the in most respects excellent monograph of Drs Finsch and Hartlaub (see note at page 758) gives ample information as to the literature and descriptions of the 448 species which, according to those learned authors, constitute its avifauna, and no attempt can possibly be made to subdivide the Subregion into provinces. Lying off its coast are three considerable islands, Pemba, Zanzibar, and Monfia, but as yet there is no reason

[1] *System der Ornithologie West Africa's.* Bremen: 1857.

to expect that they have any very important bearing from a zoogeographical point of view. Zanzibar is the best known, and that seems to have a few species peculiar to it—for instance, *Laniarius salimæ*, *L. orientalis*, and *Francolinus kirki*,—but further investigation may prove that some of them also occur on the mainland.

Madagascarian Subregion.

(5.) *The Madagascarian Subregion* remains for consideration, and this from its insularity is obviously well defined, while a good deal of attention has been paid to its remarkable peculiarities. Indeed, except New Zealand, it may be safely deemed the most peculiar Subregion on the earth's surface, while from the richness and multifariousness of its animal and especially of its ornithic population, New Zealand cannot for a moment be compared with it. Its principal subdivision, Madagascar itself, once possessed in the extinct gigantic bird *Æpyornis* a form of *Ratitæ*, not less singular than the Ostrich or the Moa, and though some writers would fain see in the remains of this marvellous creature a realization of Oriental fables respecting the Roc, not a vestige has been recovered which can be declared to belong to any period to which history or even legend can reach, and Arabian tales are not corroborated by the hypothesis of Professor Bianconi, while they are virtually contradicted by the researches at home of M. Alphonse Milne-Edwards, and Herr von Nathusius, and of M. Grandidier abroad. Three also of the satellite islands—Mauritius, Réunion (Bourbon), and Rodriguez—possessed brevipennate Birds totally dissimilar from but hardly less singular than the *Æpyornis*, and here the Dodo and its kindred, together with other Birds now extirpated, flourished peacefully till they felt the power of man and his agencies. But brief particulars of these extinct forms have already been given (pp. 732, 733), and we must now restrict ourselves to the consideration of those which survive.

This Subregion is easily divided into two provinces—Madagascar and the Mascarene Islands; but then it becomes a question whether the Comoros should not be considered to form a third, and also how the Seychelles should be treated. Not without scruples we propose to refer the latter to the Mascarene province as an outlying group, and to regard the former in the same light in reference to the Malagash province or Madagascar proper.

Malagash province.

Long studied as the Birds of Madagascar have been, hardly a year now passes without some new form being added to its list; and what is especially remarkable is that a very large proportion of the additions are not merely new species of genera previously known, but are the types of undeniably good and new genera, while it would seem also as if many of these had a very limited range in the island, for every fresh district visited by a collector is almost sure to produce something which neither he nor his predecessors have met with in other parts, though the actual distance between the localities may be inconsiderable. The number of genera of Land-birds amounts to nearly 100, and of them almost one-half are peculiar to the Subregion; by far the greatest number of them belonging to the Order *Passeres*, though the *Picariæ* are also well represented by peculiar genera, and the *Psittaci* and *Columbæ* possess to a certain extent the same characteristics. Many of the genera belonging to the two Orders first named can be but with difficulty referred to any family existing elsewhere, but for fear of exaggerating the singular character of the Subregion we prefer regarding two only of these families as absolutely peculiar. These are *Leptosomidæ* and *Eurycerotidæ*, the single genus and species constituting each of which it seems impossible to place with any other family. Almost the same may be said of the genera *Brachypteracias*, *Geobiastes*, and *Atelornis*, which may perhaps be linked in one group, though to what family it should be attached seems very doubtful; and there is *Philepitta* so isolated that by one author it is referred to the *Turdidæ*, by another to the *Paradiseidæ*, and by a third to the *Pittidæ*, the probability being that each assignation is wide of the mark. But the avifauna of Madagascar is not entirely composed of such singularities as these. We have homely genera, even among the *Passeres*, occurring there, such as *Acrocephalus*, *Motacilla*, *Pratincola*, and *Alauda*, while a *Cisticola*, which, though it has received a distinct trivial name, is undistinguishable from the well-known Fantail-Warbler (*C. schœnicola*) of southern Europe, Africa, and India, has long been known as an inhabitant of Madagascar. But there are also species, though not Passerine, which are absolutely identical with those of Britain—*Aluco flammeus*, *Coturnix communis*, *Porzana pygmæa*, and *Podiceps minor*—all of them common in the island. The number of species of Birds hitherto found in Madagascar cannot be safely put at less than 200, of which 120 are Land-birds, and of these latter fully 100 are peculiar. The Comoros, so far as they have been explored, have yielded more than 20 Land-birds, of which 12 at least are peculiar, the remainder being common to Madagascar; but, no doubt, throughout every part of the Malagash province there is room for further discoveries.

Mascarene province.

The principal islands of the Mascarene province have had their original fauna so largely destroyed by colonization, as has just been stated, that we are hardly in a condition to judge its peculiarities accurately. Mauritius and Réunion, lying within sight of each other, and possessing about the same number of existing species, seem not to have more than 3 in common. There is 1 genus (*Oxynotus*) belonging to the *Campephagidæ* which is peculiar to these two islands, and represented in each by a distinct species. Réunion also had within the memory of men yet living a peculiar genus of *Sturnidæ*—*Fregilupus*. Rodriguez is now known to possess only 4 species of Land-birds natural to it; and of these 3 are peculiar, 1 being the Parrakeet before mentioned as on the verge of extinction, and another an aberrant form of *Drymœca*, pointing possibly to a common origin with certain Indian species.[1] The Land-birds of the Seychelles which have not been introduced are 14 in number, and of these 12, according to Mr Edward Newton (*Ibis*, 1867, p. 359), are peculiar; but there is no good genus which can be so termed. Finally, we may mention that the small island of Aldabra has a Dove which has been described as a distinct species, and that of St Denis a Water-hen which probably merits the same remark. Taken as a whole, we cannot but be struck with the force of the evidence as to the land-connection which must once have existed—though not necessarily all at once—between the various units forming the whole Subregion. Even the scanty remnant that is left enables one to see how the denizens of its most distant quarters represent one another, a clear token of their long-continued isolation and the working of a differentiating power. But this is no place to pursue theories.

VI. THE INDIAN REGION[2] completes our survey of the

[1] This same leaning towards India is also indicated by the genus *Hypsipetes*, one of the *Turdidæ*, all the members of which, save 4, belong to the Indian region, and these four are peculiar respectively to Madagascar, Réunion, Mauritius, and the Seychelles, and it would be easy to cite similar cases of isolated Birds of either the Indian or Ethiopian Region which have their nearest relatives natives of the other.

[2] It must be mentioned that objection has frequently, and not without show of reason, been taken to the name "Indian" applied to this Region; and, except for the awkwardness of the title, we must admit that "Indo-Malayan" would have most likely been found a more expressive and suitable epithet, since what we commonly mean by "India" forms but a small and perhaps not the most characteristic portion. Mr Wallace proposes to use the name "Oriental," against which it may be not unreasonably urged that it errs on the side of vagueness, just as "Indian" does on the side of particularity. On the

INDIAN REGION. globe; and its boundaries, so far as they can be defined, have been already sketched out when treating of the adjoining areas. Large as is its extent, and greatly varied as are its physical features, it would seem to have but 2 peculiar families of Birds (*Phyllornithidæ* and *Eurylæmidæ*) out of upwards of 70 which occur within its limits. There is peculiar difficulty in determining the zoological Subregions and provinces into which this Region should be separated. While the fauna of some districts, or even larger portions, has been studied so that we possess a knowledge of them almost as full as of any country in the world, Europe and the tracts of other Regions settled by Europeans alone excepted, the greater part is not much better known zoologically than is the centre of Africa. Yet we cannot treat the Indian Region with the same audacity of ignorance that we did the Ethiopian, drawing our boundaries here and there in a manner which the experience of a few more years will very likely prove to be exceedingly wide of the mark, for our acquaintance with the Region now under consideration is such as to convince us that throughout its whole extent there are districts, large or small, which have an unmistakable affinity to one another, and yet appear to be cut off from all communication with their neighbours. True it is that we may readily account for this on the ground that the similarity to be observed is due to corresponding elevation above the sea-level, and that throughout the whole Region the hill-countries are, as a rule, disconnected; but such an explanation does not make our task the easier, and we are filled with the consciousness that we cannot map out the Indian Region according to the method we have hitherto followed. We find the characteristics of the Himalayan avifauna shewing themselves not only on the highlands of Southern India and Ceylon, but far away to the eastward also, as in Formosa, Hainan, and Cochin China, and again repeated in a lesser but still perceptible degree to the southward in the mountain ranges of Malacca and Sumatra. This then being the case, we think it better to follow in the main the scheme adopted by Mr Elwes, to whose essay on the geographical distribution of Asiatic Birds we have before referred (page 754). Right or wrong in his results, he has the merit of having arrived at them, as he tells us, contrary to a certain bias which he had entertained at the beginning of his investigations, and these are marked by uncommon care and a diligent study of all the means of information at that time available to him. Mr Elwes would establish three Subregions—the "Himalayan" or "Himalo-Chinese," the "Indian" (proper), and the "Malayan."

Difficulty of establishing subdivisions.

Himalo-Chinese Subregion.

(1.) *The Himalo-Chinese Subregion*, according to his view, includes all the middle slopes of the Himalayan range, from an elevation of about 3000 to 12,000 feet, and, beginning with Cashmere, extends through Nepal, Bhotan, the highlands of Assam, and thence, marching with the as yet undetermined frontier of the Palæarctic Region, to the sea-coast of China. To this Subregion belong the islands of Formosa and Hainan, and it not only includes a great part of China proper, but probably the whole of Cochin China and Siam, with the hill-country of Tennasserim and Burmah, merging into the Malayan Subregion somewhere about lat. 12° N. In its western part, he observes, it is merely a narrow border-land, in which the members of two very different faunas meet, and, being inhabited during some part of the year by nearly all the principal Palæarctic genera, and those of the proper Indian Subregion, probably includes some of the richest portions of the world. Besides this, as already remarked, its influence is felt far to the southward, even in the islands of Ceylon and Sumatra.

whole, it seems as though "Indian," having been the distinguishing term first applied to this region, had better be retained.

From what has been said above as to the way in which some of the Subregions of the Indian Region are broken up, and this Subregion especially, it is useless to attempt any partitioning of them into true zoological provinces. We can only follow Mr Elwes in taking the various countries in succession, and stating what is known of them. Cashmere is the first. Here there seems to be 171 Land-birds, referable to 116 genera; of the latter, 34 have a wide range, 32 are characteristic of the Palæarctic Region, 29 of the Indian, and 21 peculiar to or characteristic of the Himalo-Chinese Subregion. There is only 1 species peculiar to the country—a very normal Bullfinch (*Pyrrhula*) belonging to *Fringillidæ*. *Cephalopyrus*, an aberrant Titmouse (*Paridæ*), and once thought to be a peculiar genus, extends eastward so far as Simla. Of the species 70 seem to be peculiar to the Himalayan district, and 30 are common to the Palæarctic Region.

Cashmere.

Nepal is the next country of which we know enough to give any satisfactory account; and, indeed, thanks to Mr Hodgson's labours in years gone by, our knowledge of its zoology is very tolerably complete, though of late years little has been added to it. Its rich avifauna is said to consist of 553 species of Land-birds, belonging to 294 genera; of the latter, 62 are of wide range, 30 characteristic of the Palæarctic, and 122 of the Indian Region, while 80 are peculiar to, or characteristic of, the Himalaya. Of the species there are 330 peculiar to the Himalayan district, and 60 common to the Palæarctic Region.

Nepal.

The small state of Sikkim seems to be richer still Excluding the *Accipitres* there are here found 423 species of Land-birds, of which 270 do not occur out of the Himalaya, except as migrants or stragglers. Of these, 63 belong to genera of wide range, 60 more are of Palæarctic distribution, and 154 are nearly peculiar to the Indian Region, while 146 are peculiar to, or characteristic of, the Himalo-Chinese Subregion. Passing to Assam, the hills to the north and east of which, however, are very little known, its ornithic character seems greatly to resemble that of Sikkim; but we have from its southern boundary a few genera which are not actually found in the Himalaya, such as *Anthreptes*, *Turdinus*, and *Rhytoceros*, belonging respectively to *Nectariniidæ*, *Timeliidæ*, and *Bucerotidæ*, while we are acquainted with only 16 species which are not found also in Sikkim, and of these one-half are Burmese.

Sikkim.

Burmah must be taken next, though a district intervenes of which we are quite ignorant, and this country, its highlands especially, requires much more exploration, but the valley of the Irrawadi, Aracan, and Pegu are very fairly known. Of 373 species of Land-birds, 97 are common to India, and the rest to the Malay peninsula. 193 more are found in India, and 27 in the peninsula alone, while 46 are peculiar to Burmah or to Burmah and Tennasserim. In Tennasserim, taking it to extend from Martaban to the isthmus of Krau, we have 313 species of Land-birds, 93 being common to India and the rest of the peninsula, 117 more being found in India, and 56 in the peninsula alone, while 47 are peculiar to Tennasserim or to Tennasserim and Burmah. This country is especially rich in species of the peculiarly Indian family *Eurylæmidæ*, possessing a majority of the known forms.

Burmah and Tennasserim.

Lying in the Bay of Bengal are two remarkable groups of islands—the Andamans and the Nicobars—which the authority we are following would, from the similarity of their avifauna to that of Pegu, include in this Subregion. Lord Walden, however, thinks (*Ibis*, 1873, p. 297) the former have a greater affinity to the highlands of India south of the Himalaya and west of the Brahmapootra, and Mr Hume (*Stray Feathers*, ii. p. 136) considers both groups to form an outlying bit of the proper Indian Subregion on which many foreign intruders have established

Andamans and Nicobars.

themselves. It is certain that many genera, or even families, which are common in Burmah are wanting in the Andamans, such as the *Timeliidæ*, *Pittidæ*, *Eurylæmidæ*, and *Bucerotidæ*, though a peculiar form of the last occurs on Narcondam, an island between the Andamans and Burmah, and there is an extreme paucity of several other families. Still the Andamans possess an avifauna of some 155 species, 17 of which (all Land-birds) are peculiar. The precise number of species found in the Nicobars is not explicitly stated by Mr Hume, but he gives 10 as peculiar to that group, which is inhabited by two very noteworthy forms—*Calœnas*, a very remarkable genus of *Columbidæ*, widely spread throughout the Malayan archipelago, and a species of *Megapodius*, belonging to one of the most characteristic families of the Australian Region. The presence of these two forms would almost incline one to remove the Nicobars from the Subregion to which they have generally been assigned, and refer them rather to the Malayan Subregion.

China. It is now necessary to retrace our steps northward and notice China;[1] but this is a branch of the subject on which it is as yet impossible to form an opinion. The chief authority on Chinese ornithology is unquestionably Mr Swinhoe, who has for so long a time laboured in various parts of that country equally as a public servant and a naturalist; but the results of his multitudinous contributions to our knowledge of its avifauna have never yet been tabulated, and probably their author is alone competent to perform this task without running into errors that would be disastrous in their consequences. In his latest catalogue of the Birds of China,[2] he enumerates 675 species as found in that country and its islands; but valuable and carefully-drawn up as this list is, it is impossible to eliminate therefrom the species not strictly belonging to that part of the Celestial Empire which lies within our present bounds; or even were this possible, an intimate acquaintance with its ornis would be required to separate the birds-of-passage from the residents, and still more to classify them according to their several Orders and families. Add to this, that assiduously as Mr Swinhoe has himself worked in the field, and diligently as he has availed himself of such information as he could obtain from other trustworthy observers, only the outskirts of this great territory have, with few exceptions, been examined. Much is it to be hoped that he will be able in due time to bring forth the ripe fruit of his labours, but meanwhile the attempt to elucidate the peculiarities of the avifauna of China proper, that is, south at least of the Yangstzekiang and of Cochin China, would be vain if not misleading.

The two principal islands lying off the Chinese coast, however, are in a different condition. One of them has been extremely and the other tolerably well ransacked by Mr Swinhoe. In Formosa he has found 144 species, referable to 102 genera, of which 98 are found in the Himalayan Subregion, and 70 in the Malayan. The species may be thus assorted:—74 belong to wide-ranging genera, 47 to genera common to the Himalayan and Malayan Subregions, 18 are peculiar to, or characteristic of, the former Subregion, and 5 to China itself; 18 are not found in the Malayan Subregion, and no less than 34 are peculiar to the island. For Hainan Mr Swinhoe has enumerated 130 species belonging to 96 genera, of which latter 86 are common to the Malayan Subregion, and 93 to the Himalayan. Of the species 54 belong to wide-ranging genera, 59 to genera characteristic of the Indian and 16 of the Palæarctic Region, while 16 are believed to be peculiar to the island.

Formosa.

Hainan

Indian Subregion. (2.) *The Indian Subregion*, still following Mr Elwes, is the next to be considered. This consists of the remainder of the peninsula of India lying to the south and west of the last, as well as of the island of Ceylon. Its partition into provinces has been several times attempted, and doubtless the method proposed by Mr Blanford, when treating of the geographical distribution of Indian Reptiles,[3] is one of the most reasonable, but even this may perhaps be premature,[4] and here it seems preferable to abstain from doing more than consider, so far as materials are available, the avifauna of the various districts of which it is composed—the more so since the extraordinary impulse given to the study of ornithology in India by the publication of the late Dr Jerdon's work[5] will doubtless in a few years place the whole subject in a very different light, for the number of Indian ornithologists is grown so considerable that that country has now a journal especially devoted to the record of their observations.

North-west of India. Beginning in the north-west with the Punjaub, we have as yet no complete list of the Birds of this most important district, and we can only infer that we shall here find the Malayan influence at its least, and the Palæarctic at its greatest; but descending the Indus to Sindh we have a discursive account of its ornithology by Mr Hume,[6] from which Mr Elwes gives the following results:—of 150 species observed, 41 are peculiarly desert-forms, and as such either very nearly allied to or identical with the like forms of the Palæarctic and Ethiopian Regions; 40 are peculiar to the Indian Subregion, 8 are common to the Malayan, 4 to the non-desert portions of the Ethiopian, and 12 to the similar parts of the Palæarctic Region, while 45 do not come under any of these heads. Omitting the desert-forms as not leading to any just conclusion, it would appear that Sindh has less affinity to the Ethiopian Region than to the Palæarctic, that is to say, to its Mediterranean Subregion. The very remarkable district of Cutch yielded 115 Land-birds to Stoliczka,[7] and these were mostly migrants or common Indian species of wide range.

Of Rajpootana and Central India we know very little, but near Goona, about 200 miles to the south of Agra, Dr King some years since observed 116 species of Land-birds;[8] and more lately Mr Adam has noticed 171 species of Land-birds around the Sambhur Lake in its western portion.[9]

Oudh. We must next turn eastward to Oudh, wherein Col. Irby (*Ibis*, 1861, p. 217) obtained 108 species of Land-birds, but of these 23 were found only on the hills of Kumaon. There seems to be a remarkable absence of many of the most widely-spread genera of the Region, and many forms generally common to Africa are also wanting; but no doubt Mr Brooks, who has of late industriously investigated this portion of the country, will be able to supply some of these unaccountable deficiencies.

Central provinces of India. We may judge of what are politically known as the "Central Provinces" of India, as well as of Bundelcund, Malwa, and Chota Nagpore, forming the "Gangetic" sub-province of Mr Blanford, from observations made by that gentleman and Colonel M'Master,[10] wherein 190 species of Land-birds are enumerated, of which 38 have a very wide range, 57 belong to widely-ranging genera but are almost

[1] Of China proper Mr Elwes says little, but he includes Eastern Thibet in this Subregion. The present writer, however, is disposed to refer that, or at any rate the scene of Père David's discoveries, to the Palæarctic Region.

confined to India, 37 to genera common to tropical Africa and India, 8 to genera of Ethiopian type, and 53 to purely Indian genera.

Deccan. Pursuing our way southward we come to the Deccan or table-land of India, and our information respecting its ornis chiefly rests on the catalogue given by Sykes many years ago,[1] which only contains about 150 species of Land-birds, of which about 105 belong to genera common to the Himalayan and Malayan Subregions, 27 to Himalayan but not Malayan genera, 30 to genera having Ethiopian or Palæarctic affinity, and the rest to widely-ranging genera or to genera peculiar to the Indian Subregion.

Southern India. The avifauna of Southern India seems to be small relatively to the extent and variety of the country, and most of its peculiar species are said to have a considerable range of latitude, though some, which are restricted to the highest hills, are only found to the southward of lat. 12° N., where several mountain-ranges reach the height of 8000 feet. No single comprehensive list of the Birds of this part of India seems lately to have been put together, and Mr Elwes gives us no statistics as the result of his investigations whereby we may compare its ornithic products with those of other districts.

Ceylon. Ceylon has profited by the residence of several competent naturalists—especially Mr Layard and Mr Holdsworth, and taking also its isolation into account, we are in a position to speak of this island with greater certainty than of the preceding portions of the Subregion. The latter of these gentlemen gives a list[2] numbering 323 species, of which 224 are Land-birds, and an analysis shows that, though 37 species are peculiar, only 4 belong to genera not found in Southern India, 22 belong to genera inhabiting the Himalaya but not the Malayan Subregion, and only 6 to Malayan but not Himalayan genera, while 14 are members of genera only found in India.

Malayan Subregion. (3.) *The Malayan Subregion* is the last of which we have to treat, and we have already hinted that it possibly has a connection with the Indian through the Nicobar Islands, but of course the most intimate communication between the two exists on the mainland. **Malay Peninsula.** The birds of its continental portion, the Malay Peninsula, have never formed the subject of a separate memoir, and to compile a complete list of them at present is a task which a more competent author has found impossible. Stoliczka has given us a catalogue[3] of 95 species obtained in the Wellesley Province, lying opposite to Penang, and numerous species have been constantly described by various authors as coming from Malacca or Singapore, which in most cases probably means that the specimens have been purchased at one of those places. To enter into any details with respect to the Malay Peninsula, therefore, would here be impossible, but the case is different as regards the islands which form the greater part of the Subregion.

Philippines. The Philippines, for more than a century, have supplied European ornithologists with materials of study, yet it is little more than ten years ago that any attempt to compile a complete list of their Birds was made, and that list, by Dr von Martens,[4] was manifestly imperfect. It is only since the present article was begun that a satisfactory account of their avifauna has appeared. This is the work of Lord Walden,[5] and we here avail ourselves of the results which he has so ably set forth. He enumerates 219 species, of which 150 are Land-birds; but in consequence of the caution he has exercised, it is most probable that this number is really too small. Of these, 106 species are peculiar to the archipelago—96 of them being Land-birds. There is no species, he remarks, which is common to the Philippines and the neighbouring island of Celebes which does not also possess a more extended range, and there is only one genus—*Prioniturus*, a very singular form of *Psittaci*—common to both and yet found nowhere else. The genera peculiar to the group are 11 in number—*Pseudolalage* belonging to *Campephagidæ*, *Zeocephus* to *Muscicapidæ*, *Rhabdornis* to *Certhiidæ*, *Sarcops* to *Sturnidæ*, *Penelopides* to *Bucerotidæ*, *Dasylophus* and *Lepidogrammus* to *Cuculidæ*, *Pseudoptynx* to *Strigidæ*, *Phabotreron* and *Ptilocolpa* to *Columbidæ*, and *Amaurornis* to *Rallidæ*. There is also only 1 species common to one of the Philippines—the island of Negros—and to one other island. This is *Xantholæma rosea*, which is also found in Java, and seems to be the representative of the widely-spread *X. hæmatocephala*, which ranges over India, Malacca, and Sumatra, but is not found either in Java or Negros. It will thus be seen that the amount of peculiarity exhibited by the avifauna of the Philippines is very great, but it must be observed that hardly anything is as yet known of Palawan or the Sooloo cluster—islands which connect the Philippines with Borneo.

Borneo. Borneo is the next island to which our attention should be directed, and this magnificent country, large enough as Mr Wallace has remarked for the whole of the United Kingdom to be set down in its midst and hidden, has lately had its avifauna carefully investigated by Dr Salvadori, the result of whose labours was published in 1874.[6] The following may be given as a summary of them. There are 392 species, of which 325 are Land-birds, 27 belonging to the Order *Accipitres*, 4 to *Psittaci*, 99 to *Picariæ*, 172 to *Passeres*, 14 to *Columbæ*, and 9 to *Gallinæ*. Yet there are only 3 unquestionably peculiar genera[7]—*Pityriasis*, a most singular form, doubtfully referred to *Laniidæ*, *Schwaneria* belonging to *Muscicapidæ*, and *Heterococcyx* to *Cuculidæ*. There are 58 or 59 peculiar species, all but 1 Land-birds, and at least 25, or perhaps as many as 32, which have no representatives elsewhere. Of Land-birds Borneo has, in common with Malacca and Sumatra, 226 species; in common with Java, 149; with the Philippines, 25; with the Indian Subregion, 53; with China, 72; and with Celebes, 28. A species of *Megapodius* (*M. cumingi*) is found in Borneo and also in the Philippines,[8] and its presence in both, like that of a member of the same genus in the Nicobars already noticed, is a very remarkable fact.

Banca. The comparatively little known island of Banca, lying between Borneo and Sumatra, produces 2 peculiar species of *Pittidæ*, the one representing a species which inhabits the whole Subregion and extends to China and Siam, the other allied to two species, the first ranging from Nepal to Malacca, and the second inhabiting the Philippines, Borneo, and Sumatra.[9]

Sumatra. Sumatra must be considered next, or perhaps it ought to have been taken after Malacca, from which it is divided by so narrow a channel. The greater part of this island its northern half especially, is unknown, and not more than 240 species can be assigned to it, of which about 20 appear to be peculiar. Its avifauna is much allied to that

2 *Op. cit.*, 1872, pp. 404–483.

3 *Journ. As. Soc. Beng.* 1870, pp. 277–334. This, however, must not be read without referring to Lord Walden's remarks on it (*Ibis*, 1871, pp. 158–177).

4 *Journal für Ornithologie*, 1866, pp. 5–31.

5 *Transactions of the Zoological Society*, ix. pp. 125–252.

6 *Annali del Museo Civico di Storia Naturale di Genova*, v. pp. 1–430.

7 A reputed fourth, *Anais*, referred to *Artamidæ*, is suspected to be founded on a manufactured specimen! *Lobiophasis*, since established by Mr Sharpe (*Ann. and Mag. Nat. Hist.* Ser. 4, xiv. p. 373), and belonging to *Phasianidæ*, probably makes another.

8 Mr Sharpe, however, considers the species distinct (*Proc. Zool. Soc.* 1875, p. 111).

9 But on this point compare Mr Hume's remark (*Stray Feathers*, ii. p. 475).

both of Malacca and of Borneo, but it seems to have much less peculiarity than the latter's.

Java. We then have Java, the best-explored, the most thickly-peopled, and, proportionately to its fauna, the most peculiar, perhaps, of the Indo-Malay Islands. Here we find about 270 species of Land-birds, of which about 45 are peculiar—most of them being from the mountains in the western part of the island. The reappearance in Java of several Burmese species, as *Crypsirhina varians*, *Picus analis*, *Pavo muticus*, and others, which do not occur in the Malay Peninsula south of Penang, is very remarkable.

Bali. Of Bali, so interesting as the southern outpost of the Region, we only know from Mr Wallace that he saw there several Birds highly characteristic of Javan ornithology, and whether the island has any peculiar species nowhere appears. We are then brought to the brink of that remarkable strait through which runs "Wallace's Line," and crossing it find ourselves at once in the Australian Region, with which we began this protracted dissertation.

Uniformity and completeness of treatment impossible. It is, of course, much to be regretted that at present our information does not allow of our treating all the Six Zoological Regions of the globe on a uniform plan, or of dealing equally with their several component portions. That this will be possible in a few years, as materials are accumulated, none can doubt; but as yet we are far from the attainment of so desirable an end, and must be content to make the most of what we have. Want of space, also, has hindered the proper consideration here of many points that fully deserve notice, and especially the negative characteristics of the different Regions—often quite as important as those which are positive. Of the imperfections of the preceding sketch no one can be more painfully aware than its author, but its very imperfections may serve a useful purpose in drawing attention to the districts about which least is known. Yet it would be affectation for him not to believe that it has some actual merit, but that merit is greatly if not chiefly due to the kindness of Mr Wallace, who, in the manner already stated, has allowed his forthcoming work to be laid under contribution, though in several respects its conclusions are not here adopted. That work, when published, will unquestionably form a foundation on which a noble superstructure will ultimately be erected, but it were vain to anticipate the ends which such a building will one day serve, and it would be beyond our scope to enter into any theoretical disquisition on the deductions which follow from the facts here advanced.

MIGRATION.

Most strangely and unaccountably confounded by many writers with the subject of Distribution is that of Migration. True it is that owing to the vast powers of locomotion possessed by nearly all Birds, we have individuals belonging in the main to certain groups, but by no means always confined to them, straying from their proper quarters and occurring in places far removed, not only from the land of their birth, but from the country whither they are ordinarily bound in their journeys, to reach which is the object wherefore such journeys are undertaken. It may be that in some measure this erraticism is governed by fixed laws, and indeed indication is not wanting that such laws exist, though as yet we know much too little to lay them down with any approach to confidence. But it is obvious on reflection that granting the existence of most rigorous laws of this kind—determining the flight of every winged vagabond—they must be very different from those which are obeyed by Birds commonly called "Migratory," and migrating year after year according to a more or less fixed rule from one locality to another with the seasons as they roll. The former laws would seem to be created or controlled by purely external circumstances, which if they possess any periodicity at all possess a periodicity of cycles, and are most likely dependent in the main on cycles of the weather, but on this point observation has not yet supplied us with the means of avoiding speculation. We may indeed say almost without much risk of error that so many individuals of a foreign species—whether North-American or Asiatic—will occur in Great Britain so many times in the course of a term of years; but, though we may safely predict that if they appear at all they will do so at a certain season, it is impossible to make a forecast as to the year in which an example will turn up, or whether in one year some half-dozen may or may not occur. The matter thus becomes a matter of averages, and like all such is open to the influence of many perturbants, not that such may not well be subject to some law of which we are ignorant. Besides this, the average is hard to strike, depending as it must on the existence of favourably-placed and watchful observers. Moreover if we consider that the number of competent observers, though possibly greater in England than anywhere else in the world, has been at all times small, it is not surprising that little has been effected towards the compassing of any definite notion on this head. At present we can but attribute the appearance of foreign stragglers on our shores, and no doubt the same may be said of other countries, to the influence of storms which have driven the wanderers from their course, and though other more remote causes may possibly be assigned, there seems to be none but this on which we can safely rely. Consequently until the periodicity of storms is brought within our knowledge we must be content to abide in our ignorance of the laws which govern the appearance of the strangers. Still confining our remarks to the British Islands, the effect of these laws is in some degree constant. Singular as it may appear, the greatest number of North-American Birds—and especially of the *Limicolæ*, or Shore-birds, which are recorded as having occurred in this country have been met with in the eastern part of England or Scotland. There are two ways of accounting for this fact, the first of which is the unfortunate scarcity of observing naturalists in Ireland and on its western coast especially, and this is by no means to be overlooked; but it may be remarked that in no part of the United Kingdom is the profession of the gunner more enthusiastically followed than in the sister island, and the men who pursue that vocation are all alive to the mercantile value of any strange bird which may fall in their way. Of course they have no means of knowing what it is, yet as their spoils are sent for sale to the nearest market, it cannot but happen that if many examples of North-American species were procured by them, some proportion of these would find their way to the notice of the amateur naturalist and by him be recorded in the public prints.[1] Now, as compared with Great Britain, this so rarely occurs in Ireland that it is by no means unfair to draw the inference that Transatlantic Birds are there far less frequently met with. The second mode of accounting for the fact above stated is that the majority of North-American Birds which occasionally visit Europe are of species which breed in somewhat high northern latitudes. On their way thence to their winter-quarters, some are driven out to sea by violent westerly gales—the strongest winds, be it remembered, that prevail

Migrations apparently irregular may yet conform to laws.

Appearance of American Birds in Britain.

[1] It seems also not unlikely that the very scarcity of rare birds in Ireland is one reason why there are so few ornithologists in that country, for here it is not uncommon for a man to have his attention first called to zoology by meeting with some strange animal—be it beast, bird, beetle, or butterfly, and for such a man afterwards to become no mean field-naturalist.

in the North Atlantic, and thus strike the coast of Norway.[1] In that country observers may be said to be practically absent, and fowlers as a rule unknown. Such storm-beaten wanderers there consort with the allied species to be found at that season in abundance on its shores and in their company pursue the same southerly course. With them they cross to the east of Great Britain, and once arrived here are speedily picked out and secured by the practised gunner. But should they even escape his notice, they with their comrades follow the shore-line, where they obtain the best supply of food, until passing round the south coast they find themselves at the western extremity of England—the district of the Land's End, in which, next to Norfolk and Suffolk, the greatest number of these Transatlantic stragglers have been obtained. This suggestion may serve to shew what most likely goes on in other parts of the world, though the materials for establishing its general truth are not forthcoming.

Migration proper.

But returning to the subject of Migration proper, distinguished as it ought to be from that of the more or less accidental occurrence of stray visitors from afar, we have here more than enough to excite our wonder, and indeed are brought face to face with perhaps the greatest mystery which the whole animal kingdom presents—a mystery which attracted the attention of the earliest writers, and can in its chief point be no more explained by the modern man of science than by the simple-minded savage or the poet or prophet of antiquity. Some facts are almost universally known and have been the theme of comment in all ages and in all lands. The Hawk that stretches her wings toward the south is as familiar to the latest Nile-boat traveller or dweller on the Bosphorus as of old to the author of the book of Job. The autumnal thronging of myriads of Waterfowl by the rivers of Asia is witnessed by the modern sportsman as it was of old by Homer. Anacreon welcomed the returning Swallow, in numbers which his imitators of the colder north, to whom the associations connected with it are doubly strong, have tried in vain to excel. The Indian of the Fur-Countries in forming his rude calendar names the recurring moons after the Birds-of-passage whose arrival is coincident with their changes. But there is no need to multiply instances. The flow and ebb of the mighty feathered wave has been sung by poets and reasoned of by philosophers, has given rise to proverbs and entered into popular superstitions, and yet we must say of it still that our "ignorance is immense."

Exploded fancy of hibernation.

On one point and one only in connection with this subject can we boast ourselves to be clearly wiser than our ancestors. Some of them fully believed that the seasonal disappearance of the Swallow, the Nightingale, the Cuckow, and the Corncrake was due to hibernation, while others indeed doubted whether or not this was the true explanation of the fact. It is not so long since this belief and these doubts were in vogue, but now assuredly they have no hold upon the mind of any one capable of appreciating evidence, and this absurd fancy being exploded need not again trouble us.

Chief facts of migration.

In considering the phænomena of Migration it will be best first to take the facts, and then try to account for their cause or causes. That a very large number of Birds all over the world change their abode according to the season is well known, and we find that in almost all countries there are some species which arrive in spring, remain to breed, and depart in autumn; others which arrive in autumn, stop for the winter, and depart in spring; and others again—and these are strictly speaking the "Birds of Passage"—which shew themselves but twice a year, passing through the country without staying long in it, and their transient visits take place about spring and autumn. People who have given but little thought to the subject are apt to suppose that these migrants, which may thus easily be classed in three categories, are acted upon by influences of different kinds, whereas very little reflection will shew that all are really affected by the same impulse, whatever that may be, and that the at first sight dissimilar nature of their movements is in truth almost uniform. The species which resort to this and to other temperate countries in winter are simply those which have their breeding-quarters much nearer the poles, and in returning to them on the approach of spring are but doing exactly as do those species which, having their winter-abode nearer the equator, come to us with the spring. The Birds-of-passage proper, like our winter-visitants, have their breeding-quarters nearer the poles, but, like our summer-visitants, they seek their winter-abode nearer the equator, and thus perform a somewhat longer migration. So far there is no difficulty and no hypothesis—the bringing together of these three apparently different categories is the result of simple observation.

Partial migrants.

This however is not the only fact which is evident on the most cursory examination. To take the birds of the British Islands as an example (though exactly similar cases are presented in other countries) we find that while there are some species, such as the Swallow or the Fieldfare, of which every individual disappears at one period of the year or another, there are other species, such as the Pied Wagtail or the Woodcock, of which only the majority of individuals vanish—a few being always present[2]—and these species form the so-called "Partial Migrants." If we extend our view and look to birds on the continent of Europe, we find that many species are there notoriously migrant which are not generally suspected to be so in this country—such as the Song-Thrush and the Redbreast, both of which species closer observation has proved to be with us subject to the migratory impulse. In respect of the former it is known that towards the end of summer or in autumn our native Song-Thrushes receive a considerable accession in numbers from the birds which arrive from the north, though the immigration is by no means so well marked as it is in Belgium, France, or Germany, where the arrival of the strangers sets all the fowlers to work, and the beginning of the *Chasse aux Grives* or *Drosselzug* is regarded in many places nearly as the Twelfth of August or the First of September is with us. In most localities in Britain the new comers depart after a short sojourn, and are accompanied by so many of the home bred birds that in some parts of the island it may be safely declared that not a single Song-Thrush can be found from the end of November to the end of January, while in others examples can always be seen. Much the same may be said of the Redbreast. Undeniably resident as a species, attentive scrutiny will reveal the fact that its numbers are subject to very considerable variation according to the season of the year. At no time do our Redbreasts collect in bands, but towards the end of summer they may be seen in the south of England successively passing onward, the travellers being mostly if not wholly young birds of the year; and so the great majority disappear, departing it may be safely presumed for more southern countries, since a few weeks later the markets of most towns first in France and then in Italy are well supplied with this species. But the migratory influence affects, though in a less degree, many if not most of the Redbreasts that remain with us. Content during the autumn to occupy their usual haunts,

Song-Thrush.

Redbreast.

[1] Prof. Baird's remarks on this subject are much to the point (*Am. Journ. Sc.*, ser. 2, xli. pp. 344, 345).

[2] Whether these few be not migrants from another district is a point that would require further consideration.

the first sharp frost has a decided effect upon their distribution, and a heavy fall of snow drives them towards the homesteads for the larger supply of food they find there, while should severe and long-continued hard weather follow even these birds vanish, leaving only the few which have become almost domesticated.

Migration almost universal.

These two species have been here chosen as illustrative cases because they are at once plentiful and familiar, and want of space only forbids us from citing others, but we shall find on inquiry that there is scarcely a Bird of either the Palæarctic or Nearctic Region, whose habits are at all well known, of which much the same may not be said, and hence we are led to the conclusion that every Bird of the northern hemisphere is to a greater or less degree migratory in some part or other of its range. Such a conclusion brings us to a still more general inference—namely that Migration, instead of being the exceptional characteristic it used formerly to be thought, may really be almost universal, and though the lack of observations in other, and especially tropical, countries does not allow us to declare that such is the case, it seems very probable, to be so. Before proceeding however to any further conclusions it is necessary to examine another class of facts which may possibly throw some light on the matter.

Affection for old breeding-places.

It must be within the experience of every one who has ever been a birds'-nesting boy that the most sedentary of Birds year after year occupy the same quarters in the breeding season.[1] In some instances this may be ascribed, it is true, to the old haunt affording the sole or the most convenient site for the nest in the neighbourhood, but in so many instances such is not the case that we are led to believe in the existence of a real partiality, while there are quite enough exceptions to shew that a choice is frequently exercised. The same may equally be said of the most migrant of Birds, and perhaps the strongest instance that has ever come to the knowledge of the writer refers to one of the latter. A pair of Stone-Curlews (*Œdicnemus crepitans*)—a very migratory species, affecting almost exclusively the most open country were in the habit of breeding for many years on the same spot though its character had undergone a complete change. It had been part of an extensive and barren rabbit-warren, and was become the centre of a large and flourishing plantation.

Want of food the most obvious cause of migration.

With these two sets of facts before us we may begin to try and account for the cause or causes of Migration. In some cases want of food would seem to be enough, as it is undoubtedly the most obvious cause that presents itself to our mind.[2] The need which all animals have of finding for themselves proper and sufficient sustenance is all-powerful, and the difficulties they have to encounter in obtaining it are so great that none can wonder that those which possess the power of removing themselves from a place of scarcity should avail themselves of it, while it is unquestionable that no Class of animals has this facility in a greater degree than Birds.[3] Even among many of those species which we commonly speak of as sedentary, it is only the adults which maintain their ground throughout the year.

Banishment of young.

It has long been known that Birds-of-prey customarily drive away their offspring from their own haunts so soon as the young are able to shift for themselves. The reason generally, and no doubt truly, given for this behaviour, which at first sight appears so unnatural, is the impossibility of both parents and progeny getting a livelihood in the same vicinity. The practice, however, is not limited to the Birds-of-prey alone, but is much more universal. We find it to obtain with the Redbreast, and if we watch our feathered neighbours closely we shall perceive that most of them indulge in it. The period of expulsion, it is true, is in some Birds deferred from the end of summer or the autumn, in which it is usually performed, until the following spring, when indeed from the maturity of the young it must be regarded as much in the light of a voluntary secession on their part as in that of an act of parental compulsion, but the effect is ultimately the same.

Exceptional cases.

These cases, however, which make certainly the exception rather than the rule, we can account for in another manner. It is to be observed that they are confined to species having a peculiar mode of life, the individuals associating in family-parties to form small bands. The members of the Titmouse-family (*Paridæ*) offer a good instance of this peculiarity, but it requires no very abstruse reflection to perceive that the adoption of this habit is one eminently conducive to the easy attainment of their food, which is collected, as it were, into particular spots often far apart, but where it does occur occurring plentifully. Thus a single Titmouse searching alone might hunt for a whole day without meeting with a sufficiency, while if a dozen are united by the same motive it is hardly possible for the place in which the food is lodged to escape their detection, and when discovered a few call-notes from the lucky finder are enough to assemble the whole company to share the feast. It is impossible to watch a band of any species of Titmouse, even for a few minutes, without arriving at this conclusion. One tree after another is visited by the active little rovers, and its branches examined: if nothing be forthcoming away goes the explorer to the next that presents itself, merely giving utterance to the usual twitter that serves to keep the body together. But if the object of search be found, another kind of chirp is emitted, and the next moment the several members of the band are flitting in succession to the tree and eagerly engaged with the spoil.[4]

Outward migration caused by scarcity of food.

The mode in which the want of sustenance produces Migration may best be illustrated by confining ourselves to the unquestionably migrant Birds of our own, northern hemisphere. As food grows scarce towards the end of summer in the most northern limits of the range of a species, the individuals affected thereby seek it elsewhere. Thus doing, they press upon the haunt of other individuals: these in like manner upon that of yet others, and so on,

---

[1] Two remarkable instances of this persistency may be noticed. The nest of a Falcon (*Falco peregrinus*) on Avasaxa—a hill in Finland somewhat celebrated as one of the most southern points whence the midnight sun may be seen—is mentioned by the French astronomer Maupertuis as having been observed by him in the year 1736. In 1799 it was rediscovered by Skjoldebrand and Acerbi. In 1853 Wolley found it tenanted, and from enquiries he made of the neighbours it was evident that such had yearly been the case so far as any one could remember, and so it was in 1855 as the writer can testify. In 1779 according to one account, in 1785 according to another, a pair of the Blue Titmouse (*Parus cæruleus*) built their nest in a large earthenware bottle placed in the branches of a tree in a garden at Oxbridge near Stockton-on-Tees. With two exceptions only, this bottle, or a second which has lately been placed close to it, has been tenanted by a pair of birds of this species from the year in which it was first occupied until 1873, when the writer saw it.—See Yarrell's *British Birds*, 4th ed. i. pp. 58, 486.

[2] Far more so than variation of the temperature, though in popular belief that probably holds the first place. But Birds generally, as compared with other Vertebrates, are but slightly affected by extremes of heat or cold, and indeed (so far as we can judge) by most climatic influences, provided only their supply of food is not affected thereby. —(*Cf.* Max Schmidt, *Zoolog. Garten*, 1865, pp. 330–340.)

[3] The only animals which approach Birds in the extent and character of their migrations are Fishes, of which there is no need here to say anything.

[4] The case is altogether different with those species which in winter form themselves into large flocks, as most of the Finches (*Fringillidæ*) and Buntings (*Emberizidæ*). The discoverer of a favourite morsel perhaps by his actions betrays what he has obtained, and accordingly his fellows may repair to the place, but it is without invitation on his part, and the only particular bond of union not entirely selfish which keeps them together is the cry of alarm with which a stranger is greeted.

until the movement which began in the far north is communicated to the individuals occupying the extreme southern range of the species at that season; though, but for such an intrusion, these last might be content to stay some time longer in the enjoyment of their existing quarters.

This seems satisfactorily to explain the southward movement of all migrating Birds in the northern hemisphere; but when we consider the return movement which takes place some six months later, doubt may be entertained whether scarcity of food can be assigned as its sole or sufficient cause, and perhaps it would be safest not to come to any decision on this point. On one side it may be urged that the more equatorial regions which in winter are crowded with emigrants from the north, though well fitted for the resort of so great a population at that season are deficient in certain necessaries for the nursery. Nor does it seem too violent an assumption to suppose that even if such necessaries are not absolutely wanting, yet that the regions in question would not supply sufficient food for both parents and offspring—the latter being, at the lowest computation, twice as numerous as the former—unless the numbers of both were diminished by the casualties of travel.[1] But on the other hand we must remember what has above been advanced in regard to the pertinacity with which Birds return to their accustomed breeding-places, and the force of this passionate fondness for the old home cannot but be taken into account, even if we do not allow that in it lies the whole stimulus to undertake the perilous voyage.

Homeward movement.

Mr Wallace on origin of migratory habits.

Mr Wallace in some remarks on the subject (*Nature*, x. p. 459) ingeniously suggests the manner in which the habit of Migration has come to be adopted:[2]—

> "It appears to me probable that here, as in so many other cases, 'survival of the fittest' will be found to have had a powerful influence. Let us suppose that in any species of migratory bird, breeding can as a rule be only safely accomplished in a given area; and further, that during a great part of the rest of the year sufficient food cannot be obtained in that area. It will follow that those birds which do not leave the breeding area at the proper season will suffer, and ultimately become extinct; which will also be the fate of those which do not leave the feeding area at the proper time. Now, if we suppose that the two areas were (for some remote ancestor of the existing species) coincident, but by geological and climatic changes gradually diverged from each other, we can easily understand how the habit of incipient and partial migration at the proper seasons would at last become hereditary, and so fixed as to be what we term an instinct. It will probably be found, that every gradation still exists in various parts of the world, from a complete coincidence to a complete separation of the breeding and the subsistence areas; and when the natural history of a sufficient number of species is thoroughly worked out, we may find every link between species which never leave a restricted area in which they breed and live the whole year round, to those other cases in which the two areas are absolutely separated."

Earlier return of male migrant.

A few more particulars respecting Migration are all that can here be given, and it is doubtful whether much can be built upon them. It has now been ascertained by repeated observation that in the spring-movement of most species of the northern hemisphere the cock-birds are always in the van of the advancing army, and that they appear some days, or perhaps weeks, before the hens. It is not difficult to imagine that, in the course of a journey prolonged throughout some 50° or 60° of latitude, the stronger individuals should outstrip the weaker by a very perceptible distance, and it can hardly be doubted that in most species the males are stouter, as they are bigger than the females. Some observers assert that the same thing takes place in the return-journey in autumn, but on this point others are not so sure, which is not surprising when we consider that the majority of observations have been made towards what is the northern limit of the range of the *Passeres*, to which the remark is especially applicable —in the British Islands, France, North Germany, and the Russian Empire—for it is plain that at the beginning of the journey any inequality in the speed of travelling will not have become so very manifest. There is also another matter to be noticed. It has been suspected that where there is any difference in the size of birds of the same species, particularly in the dimensions of their wings, the individuals that perform the most extensive journeys are naturally those with the longest and broadest *remiges*, and in support of this view it certainly appears that in some of the smaller migrants—such as the Wheatear (*Saxicola œnanthe*) and Willow-Wren (*Phylloscopus trochilus*)—the examples which reach the extreme north of Europe and there pass the summer possess greater mechanical powers of flight than those of the same species which stop short on the shores of the Mediterranean. It may perhaps be also inferred, though precise evidence is wanting, that these same individuals push further to the southward in winter than do those which are less favoured in this respect. It is pretty nearly certain that such is the case with some species, and it may well be so with individuals. Canon Tristram has remarked (*Ibis*, 1865, p. 77) that, in many genera of Birds, "those species which have the most extended northerly have also the most extended southerly range; and that those which resort to the highest latitudes for nidification also pass further than others to the southward in winter," fortifying his opinion by examples adduced from the genera *Turdus*, *Fringilla*, *Cypselus*, and *Turtur*. But supposing this to be true for many Birds, it may fairly be doubted whether it is so for all, and whether in some species certain individuals do not always occupy the most northern portion of the range and others always keep to the most southern, no matter what the season of the year may be, or over what countries the range may extend. On this point therefore it will be advisable to await further investigation.

Connection of distance with length of wing.

Presumed effects of weather on migration.

For many years past a large number of persons in different countries have occupied and amused themselves by carefully registering the dates on which various migratory Birds first make their appearance, and certain publications abound with the records so compiled.[3] Some of the observers have been men of high scientific repute, others of less note but of not inferior capabilities for this especial object. Still it does not seem that they have been able to determine what connection, if any, exists between the arrival of birds and the state of the weather. This is not very wonderful, for the movements of the migrants, if governed at all by meteorological forces, must be influenced by their action in the places whence the travellers have come, and therefore to establish any direct relation of cause and effect corresponding observations ought equally to be made in such places, which has seldom been done.[4]

---

[1] If the relative proportion of land to water in the Southern Hemisphere were at all such as it is in the Northern, we should no doubt find the birds of southern continents beginning to press upon the tropical and equatorial regions of the globe at the season when they were thronged with the emigrants from the north, and in such a case it would be only reasonable that the latter should be acted upon by the force of the former, according to the explanation given of the southward movement of northern migrants. But, though we know almost nothing of the migration of birds of the other hemisphere, yet, when we regard the comparative deficiency of land in southern latitudes all round the world, it is obvious that the feathered population of such as now-a-days exists can exert but little influence, and its effects may be practically disregarded.

[2] In principle Captain Hutton had already foreshadowed the same theory.—(*Trans. New Zeal. Inst.* 1872, p. 235.)

[3] These are far too numerous to mention here. Perhaps the most remarkable series of them is that carried on from 1736 to 1810 and again from 1836 to 1874 by four generations of the Marsham family at Stratton-Strawless and Rippon near Norwich, of which an account is given by Mr Southwell (*Trans. Norf. and Norw. Nat. Soc.* ii. p. 31).

[4] To a limited extent it must be admitted that the popular belief as to certain Birds being the harbingers of severe weather is justifiable. Cold comes from the north, and when it is accompanied, as is most gene-

As a rule it would seem as though Birds were not dependent on the weather to any great degree. Occasionally the return of the Swallow or the Nightingale may be somewhat delayed, but most Sea-fowls may be trusted, it is said, as the almanack itself. Were they satellites revolving around this earth, their arrival could hardly be more surely calculated by an astronomer. Foul weather or fair, heat or cold, the Puffins (*Fratercula arctica*) repair to some of their stations punctually on a given day as if their movements were regulated by clock-work. Whether they have come from far or from near we know not, but other Birds certainly come from a great distance, and yet make their appearance with scarcely less exactness. Nor is the regularity with which certain species disappear much inferior; every observer knows how abundant the Swift (*Cypselus apus*) is up to the time of its leaving its summer-home—in most parts of England, the first days of August—and how rarely it is seen after that time is past.

Statistics of migration. It must be allowed, however, that, with two exceptions, the mass of statistics above spoken of has never been worked up and digested so as to allow proper inferences to be made from them, and therefore it would be premature to say that little would come of it, but the result of those two exceptions is not very encouraging. Some twenty years ago Dr von Middendorff carefully collated the records of the arrival of migratory Birds throughout the Russian Empire, but the insight into the question afforded by his published labours [1] is not very great. His chief object has been to trace what he has termed the *isepipteses* (ἴσος = *æqualis*, ἐπίπτησις = *advolatus*) or the lines of simultaneous arrival, and in the case of 7 species [2] these are laid down on the maps which accompany his treatise. The lines are found by taking the average date of arrival of each species at each place in the Russian dominions where observations have been regularly made, and connecting those places where the dates are the same for each species by lines on the map. The curves thus drawn indicate the inequality of progress made by the species in different longitudes, and assuming that the advance is directly across the isepiptesial lines, or rather the belts defined by each pair of them, the whole course of the migration is thus most accurately made known. In the case of his seven sample species the maps show their progressive advance at intervals of a few days, and the issue of the whole investigation, according to him (*op. cit.* p. 8) proves that in the middle of Siberia the general direction of the usual migrants is almost due north, in the east of Siberia from south-east to north-west, and in European Russia from south-west to north-east. Thus nearly all the migrants of the Russian Empire tend to converge upon the most northern part of the continent, the Taimyr Peninsula, but it is almost needless to say that few of them reach anything like so far, since the country in those high latitudes is utterly unfit to support the majority. With the exception of some details, which, though possessing a certain special interest, need not here be mentioned, this treatise fails to shew more; for the fact that there are places that notwithstanding their higher latitude are reached by Birds on their spring-migrations sooner than others in a lower latitude was already known.

Routes of migrants. The routes followed by migratory Birds, so far as our information at present extends, has been the subject of a very exhaustive memoir by Herr Palmén,[3] but it would be impossible within the limits of the present article to do more than mention his results concisely. He enters very fully into this part of the enquiry and lays down with much apparent probability the chief roads taken by the most migratory Birds of the Palæarctic Region in their return autumnal journey, further asserting that in the spaces between these lines of flight such birds do not usually occur. These main routes are, he states, *nine* in number. The first (A—to use his notation), leaving the Siberian shores of the Polar Sea, Nova Zembla, and the North of Russia, passes down the west coast of Norway to the North Sea and the British Islands. The second (B), proceeding from Spitsbergen and the adjoining islands, follows much the same course, but is prolonged past France, Spain, and Portugal to the west coast of Africa. The third (C) starts from Northern Russia, and, threading the White Sea, and the great Lakes of Onega and Ladoga, skirts the Gulf of Finland and the southern part of the Baltic to Holstein and so to Holland, where it divides—one branch uniting with the second main route (B), while the other, running up the valley of the Rhine and crossing to that of the Rhone, splits up on reaching the Mediterranean, where one path passes down the western coast of Italy and Sicily, a second takes the line by Corsica and Sardinia, and a third follows the south coast of France and eastern coast of Spain—all three paths ending in North Africa. The fourth (D), fifth (E), and sixth (F) main routes depart from the extreme north of Siberia. The fourth (D) ascending the river Ob, branches out near Tobolsk—one track, diverging to the Volga, descends that river and so passes to the Sea of Azov, the Black Sea, and thence, by the Bosphorus and Ægean, to Egypt; another track makes for the Caspian by way of the Ural River and so leads to the Persian Gulf, while two more are lost sight of on the steppes. The fifth (E) mounts the Jennesei to Lake Baikal and so passes into Mongolia. The sixth (F) ascends the Lena and striking the Upper Amoor reaches the Sea of Japan, where it coalesces with the seventh (G) and eighth (O) which run from the eastern portion of Siberia and Kamchatka. Besides these the ninth (X) starting from Greenland and Iceland passes by the Færoes to the British Islands and so joining the second (B) and third (C) runs down the French coast. These being the main routes it must be added that, in Herr Palmén's opinion and that of many others, nearly all river-courses form minor routes.[4]

The return of birds to their former haunts seemingly inexplicable. But lay down the paths of migratory Birds, observe their comings and goings, or strive to account for the impulse which urges them forward as we will, there still remains for consideration the most marvellous thing of all—How do the birds find their way so unerringly from such immense distances? This seems to be by far the most inexplicable part of the matter. Year after year the migra-

rally the case, by heavy falls of snow, such Birds are of course driven southward to seek their living. But as often as not the Birds arrive with the kind of weather they are commonly held to prognosticate, while sometimes this does not follow their appearance.

[2] *Hirundo rustica, Motacilla alba, Alauda arvensis, Oriolus galbula, Cuculus canorus, Ciconia alba*, and *Grus communis*.

[3] *Om Foglarnes flyttningsvägar* (Helsingfors: 1874). In this and the work of Dr von Middendorff, already cited, reference is made to almost every important publication on the subject of Migration, which renders a notice of its very extensive literature needless here, and a pretty full bibliographical list is given in Prof. Giebel's *Thesaurus Ornithologiæ* (i. pp. 146–155). Yet mention may be made of Prof. Schlegel's *Over het trekken des Vogel's* (Harlem: 1828), Mr Hodgson's "On the Migration of the *Natatores* and *Grallatores* as observed at Kathmandu" in *Asiatic Researches* (xviii. pp. 122–128), and M. Marcel de Serres's *Des causes des Migrations des Animaux et particulièrement des Oiseaux et des Poissons* (Harlem: 1842). This last though one of the largest publications on the subject is one of the least satisfactory. Prof. Baird's excellent treatise *On the Distribution and Migrations of North American Birds* has been before adverted to.

[4] In giving this abstract the present writer wishes to state that he does not thereby express his agreement with all that it contains. Herr Palmén's views deserve the fullest attention from the truly scientific spirit in which they are put forward, but some of the details on which they are founded seem to require correction.

tory Wagtail will build her nest in the accustomed spot, and year after year the migratory Cuckow will deposit her eggs in that nest, and yet in each interval of time the former may have passed some months on the shores of the Mediterranean, and the latter, absent for a still longer period, may have wandered into the heart of Africa.[1] The writer cannot offer an approach to the solution of this mystery. There was a time when he had hopes that what is called the "homing" faculty in Pigeons might furnish a clue, but Mr Tegetmeier and all the best authorities on that subject declare that a knowledge of landmarks obtained by sight, and sight only, is the sense which directs these Birds, while sight alone can hardly be regarded as affording much aid to Birds—and there is reason to think that there are several such—which at one stretch transport themselves across the breadth of Europe, or even traverse more than a thousand miles of open ocean, to say nothing of those—and of them there are certainly many—which perform their migrations by night. That particular form of Bluethroat which yearly repairs to breed upon the mosses of the Subalpine and Northern parts of Scandinavia (*Cyanecula suecica*) is hardly ever seen in Europe south of the Baltic.[2] Throughout Germany it may be said to be quite unknown, being replaced by a conspicuously different form (*C. leucocyana*), and as it is a Bird in which the collectors of that country, a numerous and well-instructed body, have long taken great interest, we are in a position to declare that it is not known to stop in its transit from its winter haunts, which we know to be Egypt and the valley of the Upper Nile, to its breeding-quarters. Other instances, though none so crucial as this, could be cited from among European Birds were there room here for them. In New Zealand there are two Cuckows which are annual visitors: one, a species of *Chrysococcyx*, is supposed to come from Australia, the other, *Eudynamis taitensis* is widely spread throughout Polynesia, yet both these birds yearly make two voyages over the enormous waste of waters that surrounds the country to which they resort to breed. But space would utterly fail us were we to attempt to recount all the examples of these wonderful flights. Yet it seems impossible that the sense of sight should be the faculty whereby they are so guided to their destination, any more than in the case of those which travel in the dark.

Explanations offered:— Magnetism.

Dr von Middendorff (*op. cit.* p. 9), from the conclusions he has drawn, as before mentioned, as to the spring-movement of all birds in the Russian Empire being towards the Taimyr Peninsula, the seat of one of the magnetic poles, has suggested that the migrating Bird is always aware (he does not sufficiently explain by what means) of the situation of this point, and thus knows how to steer its course. Not only is this hypothesis unsupported by any considerations known to the writer, but it is not at all borne out by the observed facts of Migration in North America, where Birds as has been shewn by Professor Baird (*op. cit.* p. 347) do not migrate in the direction of the magnetic pole.

Instinct.

Other authors there are who rely on what they call "instinct" as an explanation of this wonderful faculty. This with them is simply a way of evading the difficulty before us, if it does not indeed remove the question altogether from the domain of scientific inquiry. Rejecting such a mode of treatment, Herr Palmén meets it in a much fairer spirit. He asserts (*op. cit.* p. 195) that migrants are led by the older and stronger individuals among them, and, observing that most of those which stray from their right course are yearlings that have never before taken the journey, he ascribes the due performance of the flight to "experience." But, granting the undisputed truth of his observation, his assertion seems to be only partially proved. Experience. That the birds which lead the flock are the strongest is on all accounts most likely, but what is there to show that these are also the oldest of the concourse? Besides this, there are many Birds which cannot be said to migrate in flocks. While Swallows, to take a sufficiently evident example, conspicuously congregate in vast flocks and so leave our shores in large companies, the majority of our summer-visitors slip away almost unobserved, each apparently without concert with others. It is also pretty nearly certain that the same species of Bird does not migrate in the same manner at all times. When Skylarks arrive on our north-eastern coast in autumn they come flitting over in a constant, straggling stream, not in compact flocks; yet a little later these same birds collect in enormous assemblages which prosecute their voyage in company. It is indeed possible that each bird of the stream intentionally follows that which goes before it, though in a long sea-passage it must be hard to keep the precursor in sight, and it may perhaps be granted that the leader of the whole is a bird of experience. But then we must consider not these cases only, but also those of Birds which do not migrate in company, and we must also have regard to what is implied in the word "experience." Here it can only signify the result of knowledge acquired on former occasions, and obtained by sight. Now it was stated by Temminck[3] many years ago, and so far as would appear the statement has not been invalidated, that among migrants the young and the old always journey apart and most generally by different routes. The former can have no "experience," and yet the greater number of them safely arrive at the haven where they would be. The sense of sight, essential to a knowledge of landmarks, as we have above attempted to demonstrate, is utterly insufficient to account for the success that attends Birds which travel by night, or in a single flight span oceans or continents. Yet without it the idea of "experience" cannot be substantiated. We may admit that inherited but unconscious experience, which is really all that can be meant by instinct, is a factor in the whole matter—certainly, as Mr Wallace seems to have proved, in originating the migratory impulse, but yet every aspect of the question is fraught with difficulty, and we must leave to time the discovery of this mystery of mysteries.

Exceptional migration.

There yet remain a few words to be said on what may be termed Exceptional Migration, that is when from some cause or other the ordinary practice is broken through. This differs from the chance occurrence of the waifs and strays with which this section of the article began in that the Birds subject to it keep in a great measure their customary habit of migrating, and yet are compelled to indulge it in an irregular, or perhaps an altogether novel, manner, though they are not entirely the sport of circumstances. The erratic movements of the various species of Crossbill Crossbills. (*Loxia*) and some allied forms afford perhaps the best-known examples. In England no one can say in what part of the country or at what season of the year he may not fall in with a company of the Common Crossbill (*L. curvirostra*), and the like may be said of many other lands. The food of these Birds consists mainly of the seeds of conifers, and as its supply in any one locality is intermittent or precarious, we may not unreasonably guess that

[1] Absolute proof of the identity of the particular birds is of course wanting, but if that objection be raised the circumstance becomes still more puzzling, for then we have to account for some mode of communicating precise information by one bird to another.

[2] It has occurred indeed as a straggler in about a dozen instances in England, and it arrives twice a year in greater or less numbers in Heligoland, as reported by the ever-watchful observer on that island, Mr Gätke, to whom ornithologists are so deeply indebted for his long-continued and intelligent scrutiny of the extraordinary number of wandering birds which alight there.

[3] *Manuel d'Ornithologie*, iii. Introd. p. xliii. note.

they shift from place to place in its quest, and may thus find an easy way of accounting for their uncertain appearance. The great band of Nutcrackers (*Nucifraga caryocatactes*) which in the autumn of 1844 pervaded Western and Central Europe[1] may also have been actuated by the same motive, but we can hardly explain the roaming of all other Birds so plausibly. The inroads of the Waxwing (*Ampelis garrulus*) have been the subject of interest for more than 300 years, and by persons prone to superstitious auguries were regarded as the forerunners of dire calamity. Sometimes years have passed without its being seen at all in Central, Western, or Southern Europe, and then perhaps for two or three seasons in succession vast flocks have suddenly appeared. Later observation has shown that this species is as inconstant in the choice of its summer- as of its winter-quarters, and though the cause of the irregularity may possibly be of much the same kind as that just suggested in the case of the Crossbill, the truth awaits further investigation.[2] One of the most extraordinary events known to ornithologists is the irruption into Europe in 1863 of Pallas's Sand-Grouse (*Syrrhaptes paradoxus*). Of this Bird, hitherto known only as an inhabitant of the Tartar steppes, a single specimen was obtained at Sarepta on the Volga in the winter of 1848. In May 1859 a pair is said to have been killed in the Government of Vilna on the western borders of the Russian Empire, and a few weeks later five examples were procured, and a few others seen, in Western Europe—one in Jutland, one in Holland, two in England, and one in Wales. In 1860 another was obtained at Sarepta; but in May and June 1863 a horde computed to consist of at least 700 individuals overran Europe—reaching Sweden, Norway, the Færoes, and Ireland in the north-west, and in the south extending to Sicily and almost to the frontiers of Spain. On the sandhills of Jutland and Holland some of these birds bred, but war was too successfully waged against the nomades to allow of their establishing themselves, and a few survivors only were left to fall to the gun in the course of the following winter and spring.[3] In the summer of 1872, another visitation to Great Britain was reported, but if it really took place it must have been that of a very small number of birds, and it was not observed on the Continent. Speculation has amused itself by assigning causes to these movements but the real reason remains in doubt.

Nut-cracker.

Waxwing.

Pallas's Sand-Grouse.

Nocturnal concourse of migrants.

We cannot quit the subject of Migration, however, without referring to the wonderful assemblages of Birds which have in various places been time and again noticed by night. Towards the close of summer, in dark, cloudy, and still weather, it not unfrequently happens that a vast and, to judge from their cries, heterogeneous concourse of Birds may be heard hovering over our large towns. The practical ornithologist will recognize the notes of Plover, Sandpiper, Tern, and Gull, now faint with distance and then apparently close overhead, while occasionally the stroke of a wing may catch his ear, but nothing is visible in the surrounding gloom. Sometimes but a few fitful wails are heard, of which only an expert listener will know the meaning. At others the continuous Babel of sounds will ensure the attention of the most incurious. It is supposed that these noises proceed from migrating birds, which, having lost their way, are attracted by the glare of the street-lamps, but far too little has been observed to remove the obscurity that in a double sense surrounds them and to enable us to come to any definite conclusion. It must be added also that such a concourse has been noticed where the fascination of light did not exist, for Lord Lilford has recorded[4] how that once at Corfu he was startled by an uproar as if all the feathered inhabitants of the great Acherusian Marsh had met in conflict overhead, but he could form no conception of what birds produced the greater part of it.

SONG.

Leaving then the subject of Migration, the next important part of the economy of Birds to be considered is perhaps their Song—a word, however, in a treatise of this kind to be used in a general sense, and not limited to the vocal sounds uttered by not more than a moiety of the feathered races which charm us by the strains they pour from their vibrating throat,—strains indeed denied by the scientific musician to come under cognizance as appertaining to his art, but strains which in all countries and in all ages have conveyed a feeling of true pleasure to the human hearer, and strains of which by common consent the Nightingale is the consummate master. It is necessary in a philosophical spirit to regard every sound made by a Bird under the all-powerful influence of love or lust as a "Song." It seems impossible to draw any but an arbitrary line between the deep booming of the Emeu, the harsh cry of the Guillemot (which, when proceeding from a hundred or a thousand throats, strikes the distant ear in a confused murmur like the roar of a tumultuous crowd), the plaintive wail of the Plover, the melodious whistle of the Widgeon, "the Cock's shrill clarion," the scream of the Eagle, the hoot of the Owl, the solemn chime of the Bell-bird, the whip-cracking of the Manakin, the Chaffinch's joyous burst, or the hoarse croak of the Raven, on the one hand, and the bleating of the Snipe[5] or the drumming of the Ruffed Grouse, on the other. Innumerable are the forms which such utterances take. In many birds the sounds are due to a combination of vocal and instrumental powers, or, as in the cases last mentioned, to the latter only. But, however produced—and of the machinery whereby they are accomplished there is not room here to speak—all have the same cause and the same effect. The former has been already indicated, and the latter is its consummation. Almost coinstantaneously with the hatching of the Nightingale's brood, the song of the sire is hushed, and the notes to which we have for weeks hearkened with rapt admiration are changed to a guttural croak, expressive of alarm and anxiety, inspiring a sentiment of the most opposite character. No greater contrast can be imagined, and no instance can be cited which more completely points out the purpose which "Song" fulfils in the economy of the bird, for if the Nightingale's nest at this early time be destroyed or its contents removed, the cock speedily recovers his voice, and his favourite haunts again resound to his bewitching strains. For them his mate is content again to undergo the wearisome round of nest-building and incubation. But should some days elapse before disaster befalls their callow care, his constitution undergoes a change and no second attempt to rear a family is made. It would seem as though a mild temperature, and the abundance of food by which it is generally accompanied, prompt the physiological alteration which inspires the males of most birds to indulge in the "Song" peculiar to them. Thus after the annual moult is accomplished, and this is believed to be the most critical epoch in the life of any bird, cock Thrushes, Skylarks, and others begin to sing, not indeed with the jubilant voice of spring but in an

Variety of Song.

Purpose of Song.

[3] *Ibis*, 1864, pp. 185-222. A few additional particulars which have since become known to the writer are inserted above.

[4] *Ibis*, 1865, p. 176.

[5] The true cause of this sound has been much discussed, but Herr Meves's explanation (*Proc. Zool. Soc.* 1858, p. 302), based on experiment, seems to be correct, though it is far from being generally accepted.

uncertain cadence which is quickly silenced by the supervention of cold weather. Yet some birds we have which, except during the season of moult, hard frost, and time of snow, sing almost all the year round. Of these the Redbreast and the Wren are familiar examples, and the Chiffchaff repeats its two-noted cry, almost to weariness, during the whole period of its residence in this country.[1]

Gestures akin to song.

Akin to the "Song" of Birds, and undoubtedly proceeding from the same cause, are the peculiar gestures which the males of many perform under the influence of the approaching season of pairing, but these again are far too numerous here to describe with particularity. It must suffice to mention a few cases. The Ruff on his hillock in a marsh holds a war-dance. The Snipe and some of his allies mount aloft and wildly execute unlooked-for evolutions almost in the clouds. The Woodcock and many of the Goatsuckers beat evening after evening the same aerial path with its sudden and sharp turnings. The Ring-Dove rises above the neighbouring trees and then with motionless wings slides down to the leafy retreat they afford. The Capercally and Blackcock perched on a commanding eminence, throw themselves into postures that defy the skill of the caricaturist—other species of the Grouse-tribe assume the strangest attitudes and run in circles till the turf is worn bare. The Peacock in pride spreads his train so as to shew how nearly akin are the majestic and the ludicrous. The Bower-bird, not content with his own splendour, builds an arcade, decked with bright feathers and shining shells, through and around which he paces with his gay companions. The Larks and Pipits never deliver their song so well as when seeking the upper air. Rooks rise one after the other to a great height and, turning on their back, wantonly precipitate themselves many yards towards the ground, while the solemn Raven does not scorn a similar feat, and, with the tenderest of croaks, glides supinely alongside or in front of his mate.[2]

NIDIFICATION.

Following or coincident with the actions just named, and countless more besides, comes the real work of the breeding-season, to which they are but the prelude or the accompaniment. Nidification is with most birds the beginning of this business; but with many it is a labour that is scamped if not shirked. Some of the Auk tribe place their single egg on a bare ledge of rock, where its peculiar conical shape is but a precarious safeguard when rocked by the wind or stirred by the thronging crowd of its parents' fellows. The Stone-Curlew and the Goatsucker deposit their eggs without the slightest preparation of the soil on which they rest; yet this is not done at haphazard, for no birds can be more constant in selecting, almost to an inch, the very same spot which year after year they choose for their procreant cradle. In marked contrast to such artless care stand the wonderful structures which others, such as the Tailor-bird, the Bottle-Titmouse, or the Fantail-Warbler build for the comfort or safety of their young. But every variety of disposition may be found in the Class. The Apteryx seems to entrust its abnormally big egg to an excavation among the roots of a tree-fern; while a band of female Ostriches scrape holes in the desert-sand and therein promiscuously dropping their eggs cover them with earth and leave the task of incubation to the male, who discharges the duty thus imposed upon him by night only, and trusts by day to the sun's rays for keeping up the needful, fostering warmth. The Megapodes raise a huge hotbed of dead leaves wherein they deposit their eggs and the young are hatched without further care on the part of either parent. Some of the Grebes and Rails seem to avail themselves in a less degree of the heat generated by vegetable decay, and dragging from the bottom or sides of the waters they frequent fragments of aquatic plants form of them a rude half-floating mass which is piled on some growing water-weed—but these birds do not spurn the duties of maternity. Many of the Gulls, Sandpipers, and Plovers lay their eggs in a shallow pit which they hollow out in the soil, and then as incubation proceeds add thereto a low breastwork of haulm. The Ringed Plover commonly places its eggs on shingle, which they so much resemble in colour, but when breeding on grassy uplands it paves the nest-hole with small stones. Pigeons mostly make an artless platform of sticks so loosely laid together that their pearly treasures may be perceived from beneath by the inquisitive observer. The Magpie, as though self-conscious that its own thieving habits may be imitated by its neighbours, surrounds its nest with a hedge of thorns. Very many birds of almost every group bore holes in some sandy cliff, and at the end of their tunnel deposit their eggs with or without bedding. Such bedding, too, is very various in character; thus, while the Sheldduck and the Sand-Martin supply the softest of materials, the one of down from her own body, the other of feathers collected by dint of diligent search,—the Kingfisher forms a couch of the undigested spiny fish-bones which she ejects in pellets from her own stomach. Other birds, as the Woodpeckers, hew holes in living trees, even when the timber is of considerable hardness, and therein establish their nursery. Some of the Swifts secrete from their salivary glands a fluid which rapidly hardens as it dries on exposure to the air into a substance resembling isinglass, and thus furnish the "edible birds' nests" that are the delight of Chinese epicures. In the architecture of nearly all the Passerine birds, too, some salivary secretion seems to play an important part. By its aid they are enabled to moisten and bend the otherwise refractory twigs and straws and glue them to their place. Spiders' webs also are employed with great advantage for the purpose last mentioned, but perhaps chiefly to attach fragments of moss and lichen so as to render the whole structure less obvious to the eye of the spoiler. The Tailor-bird deliberately spins a thread of cotton and therewith stitches together the edges of a pair of leaves to make a receptacle for its nest. Beautiful too is the felt fabricated of fur or hairs by the various species of Titmouse, while many birds ingeniously weave into a compact mass both animal and vegetable fibres, forming an admirable non-conducting medium which guards the eggs from the extremes of temperature outside. Such a structure may be open and cup-shaped, supported from below as that of the Chaffinch and Goldfinch, domed like that of the Wren and Bottle-Titmouse, slung hammock-wise as in the case of the Golden-crested Wren and the Orioles, or suspended by a single cord as with certain Grosbeaks and Humming-birds. Under such circumstances it is even sometimes needful to balance the nest lest the weight of the growing young should destroy the equipoise and, precipitating them on the ground, dash the hopes of the parents, and compensation in such cases is applied by loading the opposite

Varieties of nests.

[1] A curious question, which has as yet attracted but little attention, is whether the notes of the same species of Bird are in all countries alike. From his own observation the writer is inclined to think that it is not, and that there may exist "dialects," so to speak, of the song. (*Cf.* Gloger, *Jour. für Orn.* 1859, p. 398.)

[2] No comprehensive account of the Song of Birds seems ever to have been written. The following may be cited as the principal treatises on the subject:—Barrington, *Phil. Trans.* 1773, pp. 249–291; Kennedy, *N. Abhandl. baier. Akad.* (*Phil. Abhandl.*) 1797, p. 169; Blackwall, *Mem. Lit. and Phil. Soc. Manch.* 1824, pp. 289–323; Savart, (*Froriep's*) *Notizen u. s. w.* 1826, pp. 1–10, 20–25; Brehm and Hansmann, *Naumannia*, 1855. pp. 54–59, 96–101, 181–195, and *Journ. für Orn.* 1855, pp. 348-351, 1856, pp. 250–255. The notes of many of our common Birds are musically expressed by Mr Harting, *Birds of Middlesex* (London: 1866).

side of the structure with lumps of earth. Certain Warblers (*Aedon* and *Thamnobia*) for some unascertained reason invariably lay a piece of snake's slough in their nests—to repel, it has been suggested, marauding lizards who may thereby fear the neighbourhood of a deadly enemy. The clay-built edifices of the Swallow and Martin are known to everybody, and the Nuthatch plasters up the gaping mouth of its nest-hole till only a postern large enough for entrance and exit, but easy of defence, is left. In South America we have a family of birds (*Furnariidæ*) which construct on the branching roots of the mangrove globular ovens, so to speak, of mud, wherein the eggs are laid and the young hatched. The Flamingo erects in the marshes it frequents a mound of earth some two feet in height, with a cavity atop, on which the hen, having oviposited, sits astride with dangling legs, and in that remarkable attitude is said to perform the duty of incubation. The females of the Hornbills, and perhaps of the Hoopoes, submit to incarceration during this interesting period, the males immuring them by a barrier of mud, leaving only a small window to admit air and food, which latter is assiduously brought to the prisoners.

Occasional departure from habits.

But though in a general way the dictates of hereditary instinct are rigidly observed by birds, in many species a remarkable degree of elasticity is exhibited or the rule of habit is rudely broken. Thus the noble Falcon, whose ordinary eyry is on the beetling cliff, will for the convenience of procuring prey condescend to lay its eggs on the ground in a marsh, or appropriate the nest of some other bird in a tree. The Golden Eagle, too, remarkably adapts itself to circumstances, now rearing its young on a precipitous ledge, now on the arm of an ancient monarch of the forest and again on a treeless plain, making a humble home amid grass and herbage. Herons also shew the same versatility and will breed according to circumstances in an open fen, on sea-banks or (as is most usual) on lofty trees. Such changes are easy to understand. The instinct of finding food for the family is predominant, and where most food is there will the feeders be gathered together. This explains, in all likelihood, the associated bands of Ospreys or Fish-Hawks, which in North America breed (or used to breed) in large companies where sustenance is plentiful, though in the Old World the same species brooks not the society of aught but its mate. Birds there are of eminently social predilections. In Europe, excepting Sea-fowls—whose congregations are universal and known to all—we have perhaps but the Heron, the Fieldfare, and the Rook, which habitually flock during the breeding-season; but in other parts of the world many birds unite in company at that time, and in none possibly is this habit so strongly developed as in the Anis of the Neotropical Region, the Republican Swallow of North America, and the Sociable Grosbeak of South Africa, which last joins nest to nest until the tree is said to break down under the accumulated weight of the common edifice.[1]

Birds breeding in societies.

Parasitic Birds.

In the strongest contrast to these amiable qualities is the parasitic nature of the Cuckows of the Old World and the Cow-birds of the New, but this peculiarity of theirs is so well known that to dwell upon it would be needless. Enough to say that the egg of the parasite is introduced into the nest of the dupe, and after the necessary incubation by the fond fool of a foster-mother the interloper successfully counterfeits the heirs, who perish miserably, victims of his superior strength. The whole process has been often watched, but the reflective naturalist will pause to ask how such a state of things came about, and there is not much to satisfy his enquiry. Certain it is that some birds whether by mistake or stupidity do not unfrequently lay their eggs in the nest of others. It is within the knowledge of many that Pheasants' eggs and Partridges' eggs are often laid in the same nest, and it is within the knowledge of the writer that Gulls' eggs have been found in the nests of Eider-Ducks, and *vice versa*; that a Redstart and a Pied Flycatcher will lay their eggs in the same convenient hole —the forest being rather deficient in such accommodation; that an Owl and a Duck will resort to the same nest-box, set up by a scheming woodsman for his own advantage; and that the Starling, which constantly dispossesses the Green Woodpecker, sometimes discovers that the rightful heir of the domicile has to be brought up by the intruding tenant. In all such cases it is not possible to say which species is so constituted as to obtain the mastery, but it is not difficult to conceive that in the course of ages that which was driven from its home might thrive through the fostering of its young by the invader, and thus the abandonment of domestic habits and duties might become a direct gain to the evicted householder. This much granted, all the rest will follow easily enough, but it must be confessed that this is only a presumption, though a presumption which seems plausible if not likely.

EGGS.

The pains bestowed by such Birds (incomparably the most numerous of the Class), as build elaborate nests and the devices employed by those that, not doing so, display no little skill in providing for the preservation of their produce, invite some attention to the eggs which they lay. This attention will perhaps be more cheerfully given when we think how many naturalists, not merely ornithologists, have been first directed to the study of the animal kingdom by the spoils they have won in their early days of birds' nesting. With some such men the fascination of this boyish pursuit has maintained its full force even in old age—a fact not so much to be wondered at when it is considered that hardly any branch of the practical study of Natural History brings the enquirer so closely in contact with many of its secrets. It is therefore eminently pardonable for the victims of this devotion to dignify their passion by the learned name of "OOLOGY," and to bespeak for it the claims of a science. Yet the present writer—once an ardent follower of the practice of birds'-nesting, and still on occasion warming to its pleasure—must confess to a certain amount of disappointment as to the benefits it was expected to confer on Systematic Ornithology, though he yields to none in his high estimate of its utility in acquainting the learner with the most interesting details of bird-life—without a knowledge of which nearly all systematic study is but work that may as well be done in a library, a museum, or a dissecting-room, and is incapable of conveying information to the learner concerning the why and the wherefore of such or such modifications and adaptations of structure. To some—and especially to those who are only anatomists— this statement may seem preposterous, but it is in truth no such thing. What engineer can be said to understand his business if he knows not the purpose to which the machines he makes are to be applied and is unacquainted with their mode of working? We may investigate thoroughly the organs of any animal, we may trace them from the earliest moment in which they become defined, and

Birds' nesting

Its uses

[1] There are not many works on nidification, for "Caliology" or the study of nests has hardly been deemed a distinct branch of the science. A good deal of instructive matter (not altogether free from error) will be found in Rennie's *Architecture of Birds* (London: 1831), and there is Mr Wallace's most interesting dissertation, "A Theory of Birds' Nests," originally published in the *Journal of Travel and Natural History* (1868, p. 73), and reprinted in his *Contributions to the Theory of Natural Selection* (London: 1870). Mr Andrew Murray's and the Duke of Argyll's remarks on this essay are contained in the same volume of the *Journal* named (pp. 137 and 276).

watch them as they develop to maturity, we may comprehend the way in which every part of a complicated structure is successively built up, but if we take not the trouble to know their effect on the economy of the creature we as naturalists have done but half our task and abandon our labour when the fulness of reward is coming upon us. The field-naturalist, properly instructed, crowns the work of the comparative anatomist and the physiologist, though without the necessary education he is little more than an empiric, even should he possess the trained cunning of the savage on whose knowledge of the habits of wild animals depends his chance of procuring a meal.

Discoveries of oologists. Perhaps the greatest scientific triumph of oologists lies in their having fully appreciated the intimate alliance of the *Limicolæ* (the great group of Snipes and Plovers) with the *Gaviæ* (the Gulls, Terns, and other birds more distantly connected with them) before it was recognized by any professed taxonomist,—L'Herminier, whose researches have been much overlooked, excepted; though to such an one was given the privilege of placing that affinity beyond cavil (Huxley, *Proc. Zool. Soc.* 1867, pp. 426, 456–458; *cf. Ibis*, 1868, p. 92). In like manner it is believed that oologists first saw the need of separating from the true *Passeres* several groups of birds that had for many years been unhesitatingly associated with that very uniform assemblage. Diffidence as to their own capacity for meddling with matters of systematic arrangement may possibly have been the cause which deterred the men who were content to brood over bird's eggs from sooner asserting the validity of the views they held. Following the example furnished by the objects of their study, they seem to have chiefly sought to hide their offspring from the curious eye—and if such was their design it must be allowed to have been admirably successful. In enthusiastic zeal for the prosecution of their favourite researches, however, they have never yielded to, if they have not surpassed, any other class of naturalists. If a storm-swept island, only to be reached at the risk of life, held out the hope of some oological novelty there was the egg-collector (Faber, *Isis*, xx. pp. 633–688; Proctor, *Naturalist*, 1838, pp. 411, 412). Did another treasure demand his traversing a burning desert (Tristram, *Ibis*, 1859, p. 79) or sojourning for several winters within the wildest wastes of the Arctic Circle (Wolley, *Ibis*, 1859, pp. 69–76; 1861, pp. 92–106; Kennicott, *Rep. Smithson Inst.* 1862, pp. 39, 40), he endured the necessary hardships to accomplish his end, and the possession to him of an empty shell of carbonate of lime,[1] stained or not (as the case might be) by a secretion of the villous membrane of the parent's uterus, was to him a sufficient reward. Taxonomers, however, have probably been right in not attaching too great an importance to such systematic characters as can be deduced from the eggs of birds, but it would have been better had they not insisted so strongly as they have done on the infallibility of one or another set of characters, chosen by themselves. Oology taken alone proves to be a guide as misleading as any other arbitrary method of classification, but combined with the evidence afforded by due study of other particularities, whether superficial or deep-seated, it can scarcely fail in time to conduct us to an ornithological arrangement as nearly true to Nature as we may expect to achieve.

The first man of science who seems to have given any special thought to oology, was the celebrated Sir Thomas Browne, of Norwich, who already in 1681, when visited by John Evelyn (from whose diary we learn the fact), had assigned a place in his cabinet of rarities to a collection of birds' eggs. The next we hear of is that Count of Marsigli who early in the eighteenth century explored, chiefly for this kind of investigation, the valley of the Danube—a region at that time, it is almost unnecessary to remark, utterly unknown to naturalists. But there is no need to catalogue the worthies of this study. As they approach our own day their number becomes far too great to tell, and if very recently it has seemed to dwindle the reason is probably at hand in the reflection that most of the greatest prizes have been won, while those that remain to reward the aspiring appear to be just now from one cause or another almost out of reach. Perhaps at the present time the Birds-of-Paradise and their allies form the only group of any recognized distinctiveness and extent of whose eggs we know absolutely nothing—though there are important isolated forms, such as *Atrichia Heterolocha*, and others, concerning the eggs as well as the breeding habits of which our ignorance is absolute, and the species of many families that have hitherto defied the zeal of oologists are very numerous. These last, however, though including some common and some not very uncommon British birds, possess in a general way comparatively little interest, since, the eggs of their nearest allies being well known, we cannot expect much to follow from the discovery of the recluses, and it is only to the impassioned collector that the obtaining of such desiderata will afford much satisfaction.

Varied hues of eggs. The first thing which strikes the eye of one who beholds a large collection of egg-shells is the varied hues of the specimens. Hardly a shade known to the colourist is not exhibited by one or more, and some of these tints have their beauty enhanced by the glossy surface on which they are displayed, by their harmonious blending, or by the pleasing contrast of the pigments which form markings as often of the most irregular as of regular shape. **Forms of markings.** But it would seem as though such markings, which a very small amount of observation will show to have been deposited on the shell a short time before its exclusion, are primarily and normally circular, for hardly any egg that bears markings at all does not exhibit some spots of that form, but that in the progress of the eggs through that part of the oviduct in which the colouring matter is laid on many of them become smeared, blotched, or protracted in some particular direction. The circular spots thus betoken the deposition of the pigment while the egg is at rest, the blurred markings show its deposition while the egg is in motion, and this motion would seem often to be at once onward and rotatory, as indicated by the spiral markings not uncommonly observable in the eggs of some Birds-of-prey and others—the larger end of the egg (when the ends differ in form) making way for the smaller.[2] At the same time the eggs of a great number of birds bear, beside these last and superimposed markings, more deeply-seated stains, generally of a paler and often of an altogether different hue, and these are evidently due to some earlier dyeing process. **Ground-colour.** The peculiar tint of the ground-colour, though commonly superficial, if not actually congenital with the formation of the shell, would appear to be suffused soon after. The depth of colouring whether original or supervening is obviously dependent in a great measure on the constitution or bodily condition of the parent. If a bird, bearing in its oviduct a fully-formed egg, be captured, that egg will speedily be laid under any circumstances of inconvenience to which its producer shall be subjected, but such an egg is usually deficient in coloration—fright and

---

[1] A small proportion of carbonate of magnesia and phosphate of lime and magnesia also enters into its composition.

[2] That the larger end is protruded first was found on actual experiment by Mr Bartlett, Superintendent of the Gardens of the Zoological Society, to be the case commonly, but as an accident the position may be sometimes reversed, and this will most likely account for the occasional deposition of markings on the smaller instead of the larger end as not unfrequently shown in eggs of the Sparrow-hawk (*Accipiter nisus*). The head of the chick is always formed at the larger end.

captivity having arrested the natural secretions. In like manner over excitement or debility of the organs, the consequence of ill health, give rise to much and often very curious abnormality. It is commonly believed that the older a bird is the more intensely coloured will be its eggs, and to some extent this belief appears to be true. Certain *Falconidæ*, which ordinarily lay very brilliantly-tinted eggs, and are therefore good tests, seem when young unable to secret so much colouring-matter as they do when older, and season after season the dyes become deeper, but there is reason to think that when the bird has attained its full vigour improvement stops, and a few years later the intensity of hue begins to decline. It would be well if we had more evidence, however, in support of this opinion, which is chiefly based on a series of eggs of one species—the Golden Eagle (*Aquila chrysaetus*), in the writer's possession, among which are some believed on good grounds to have been the produce in the course of about twelve years of one and the same female. The amount of colouring-matter secreted and deposited seems notwithstanding to be generally a pretty constant quantity—allowance being made for individual constitution; but it often happens—especially in birds that lay only two eggs—that nearly all the dye will be deposited on one of these, leaving the other colourless; it seems, however, to be a matter of inconstancy which of the two is first developed. Thus of two pairs of Golden Eagles' eggs also in the possession of the writer, one specimen of each pair is nearly white while the other is deeply coloured, and it is known that in one case the white egg was laid first and in the other the coloured one. When birds lay many mottled, and *a fortiori* plain, eggs, there is generally less difference in their colouring, and though no two can hardly ever be said to be really alike, yet the family resemblance between them all is obvious to the practised eye. It would seem however to be a peculiarity with some species—and the Tree-Sparrow (*Passer montanus*) which lays five or six eggs may be taken as a striking example—that one egg should always differ remarkably from the rest of the clutch. In addition to what has been said above as to the deposition of colour in circular spots indicating a pause in the progress of the egg through one part of the oviduct, it may be observed that the cessation of motion at that time is equally shown by the clearly defined hair-lines or vermiculations seen in many eggs, and in none more commonly met with than in those of the Buntings (*Emberizidæ*). Such markings must not only have been deposited while the egg was at rest, but it must have remained motionless until the pigment was completely set, or blurred instead of sharp edges would have been the result.[1]

Effect of age on colour.

Varieties in the same clutch.

Nature of pigment.

The composition of this pigment has long excited much curiosity, and it has been commonly and rather crudely ascribed to secretions of the blood or bile,[2] but very recently unexpected light has been shed upon the subject by the researches of Mr Sorby (*Proc. Zool. Soc.* 1875, p. 351), who, using the method of spectrum-analysis, has now ascertained the existence of *seven* well-marked substances in the colouring-matter of eggs, to the admixture of which in certain proportions all their tints are due. These he names Oorhodeine, Oocyan, Banded Oocyan, Yellow Ooxanthine, Rufous Ooxanthine, a substance, giving narrow absorption-bands in the red, the true colour of which he has not yet been able to decide, and lastly Lichenoxanthine. It would be out of place here to particularize their chemical properties, and it is enough to say that they are closely connected either with hæmoglobin or bile-pigments, and in many respects resemble the latter more than do any other group of colouring-matters, but do not actually agree with them. The first is perhaps the most important of all the seven, because it occurs more or less in the shells of so great a number of eggs that its entire absence is exceptional, and it is of a very permanent character, its general colour being of a peculiar brown-red. The second and third seem when pure to be of a very fine blue, but the spectrum of the former shows no detached bands, while that of the latter has a well-marked detached absorbent-band near the red end, though the two are closely related since they yield the same product when oxidized. The fourth and fifth substances supply a bright yellow or reddish-yellow hue, and the former is particularly characteristic of eggs of the Emeus (*Dromæus*), giving rise when mixed with oocyan to the fine malachite-green which they possess, while the latter has only been met with in those of the Tinamous (*Tinamidæ*), in which it should be mentioned that oorhodeine has not been found, or perhaps in those of a Cassowary (*Casuarius*), and when mixed with oocyan produces a peculiar lead-colour. The sixth substance, as before stated, has not yet been sufficiently determined, but it would seem in combination with others to give them an abnormally browner tint; and the seventh appears to be identical with one which occurs in greater or less amount in almost all classes of plants, but is more especially abundant in and characteristic of lichens and fungi. There is a possibility however of this last being in part if not wholly due to the growth of minute fungi, though Mr Sorby believes that some such substance really is a normal constituent of the shell of eggs having a peculiar brick-red colour. That gentleman is further inclined to think that oorhodeine is in some way or other closely related to cruentine, being probably derived from the red colouring-matter of the blood by some unknown process of secretion, and likewise that there is some chemical relation between the oocyans and the bile.

Grain of the shell.

The grain of the egg-shell offers characters that deserve far more consideration than they have received until lately, when the attention of Herr von Nathusius having been directed to the subject by some investigations carried on by Dr Landois[3] and Herr Rudolf Blasius,[4] he has brought out a series of remarkable papers[5] in which he has arrived at the conclusion that a well-defined type of shell-structure belongs to certain families of birds, and is easily recognized under the microscope. In some cases, as in the eggs of certain Swans and Geese (*Cygnus olor* and *C. musicus*, *Anser cinereus* and *A. segetum*) even specific differences are apparent. The bearing of these researches on classification generally is of considerable importance and must be taken into account by all future taxonomers. Here we cannot enter into details, it must suffice to remark that the grain of the shell is sometimes so fine that the surface is glossy, and this is the case with a large number of *Picariæ*, where it is also quite colourless and the contents of their eggs seen through the semi-transparent shell give an

[1] The principal oological works with coloured figures are the following:—Thienemann, *Fortpflanzungsgeschichte der gesammten Vögel* (4to, Leipzig: 1845); Lefèvre, *Atlas des œufs des oiseaux d'Europe* (8vo, Paris: 1845); Hewitson, *Coloured Illustrations of the Eggs of British Birds* (8vo, Ed. 3, London: 1856); Brewer, *North American Oology* (4to, Washington: 1859); Taczanowski, *Oologia Ptaków Polskich* (8vo, Warszawa: 1862); Badeker, *Die Eier der Europäischen Vögel* (fol. Leipzig: 1863); Wolley, *Ootheca Wolleyana* (8vo, London: 1864)—some of which have never been completed; but a great number of rare eggs are also figured in various journals, as the *Proceedings of the Zoological Society*, *Naumannia*, the *Journal für Ornithologie*, and *The Ibis*.

[2] *Cf.* Wilke, *Naumannia*, 1858, pp. 393-397, and C. Leconte, *Revue et Magasin de Zoologie*, 1860, pp. 199-205.

[3] *Zeitschr. für wissensch. Zoologie*, xv. pp. 1-31.

[4] *Op. cit.* xvii. pp. 480-524.

[5] *Op. cit.* xviii. pp. 19-21, pp. 225-270, xix. pp. 322-348, xx. pp. 106-130, xxi. pp. 330-335. A summary of these will be found in *Journ. für. Ornith.* 1871, pp 241-260, and the subject has been continued in the same periodical for 1872, pp. 321-332, and 1874, pp. 1-26.

opalescence of great beauty; but among the Tinamous (*Tinamidæ*) colour is invariably present and their opaque eggs present the appearance of more or less globular balls of highly-burnished metal or glazed porcelain. Most birds lay eggs with a smooth shell, such as nearly all the *Gaviæ*, *Limicolæ*, and *Passeres*, and in some groups, as with the normal *Gallinæ*, this seems to be enamelled or much polished, but it is still very different from the brilliant surface of those just mentioned, and nothing like a definite line can be drawn between their structure and that in which the substance is dull and uniform, as among the *Alcidæ* and the *Accipitres*. In many of the *Ratitæ* the surface is granulated and pitted in an extraordinary manner,[1] and in a less degree the same feature is observable in the eggs of some other birds, as the Storks (*Ciconiidæ*). Many Water-fowls, and particularly the Ducks (*Anatidæ*), lay eggs with a greasy or oleaginous exterior, as the collector who wishes to inscribe his specimens with marks of their identity often finds to his inconvenience; but there are other eggs, as those of the Anis (*Crotophaga*), the Grebes (*Podicipedidæ*), and all of the *Steganopodes*, except *Phaeton*, which are more or less covered with a cretaceous film, often of considerable thickness and varied by calcareous protuberances.

Form of eggs. In form eggs vary very much, and this is sometimes observable in examples not only of the same species but even from the same mother, yet a certain amount of resemblance is usually to be traced according to the natural group to which the parents belong. Those of the Owls (*Strigidæ*) and of some of the *Picariæ*—especially those which lay the glossy eggs above spoken of—are often apparently spherical, though it is probable that if tested mathematically none would be found truly so—indeed it may be asserted that few eggs are strictly symmetrical, however nearly they may seem so, one side bulging out, though very slightly, more than the other. The really *oval* form, with which we are most familiar, needs no remark, but this is capable of infinite variety caused by the relative position and proportion of the major and minor axes. In nearly all the *Limicolæ*, and some of the *Alcidæ* the egg attenuates very rapidly towards the smaller end, sometimes in a slightly convex curve, sometimes without perceptible curvature, and occasionally in a sensibly concave curve. The eggs having this pyriform shape are mostly those of birds which invariably lay four in a nest, and therein they lie with their points almost meeting in the centre and thus occupying as little space as possible and more easily covered by the brooding parent. Other eggs as those of the Sand-Grouse (*Pterocleidæ*) are elongated and almost cylindrical for a considerable part of their length terminating at each end obtusely, while eggs of the Grebes (*Podicipedidæ*) which also have both ends nearly alike but pointed, are so wide in the middle as to present a biconical appearance.[2]

Size of eggs. The size of eggs is generally but not at all constantly in proportion to that of the parent. The Guillemot (*Alca troile*) and the Raven (*Corvus corax*) are themselves of about equal size; their eggs vary as ten to one. The Snipe (*Scolopax gallinago*) and the Blackbird (*Turdus merula*) differ but slightly in weight, their eggs remarkably. The eggs of the Guillemot are as big as those of an Eagle; and those of the Snipe equal in size the eggs of a Partridge (*Perdix cinerea*). Mr Hewitson, from whom these instances are taken, remarks:—"The reason of this great disparity is, however, obvious; the eggs of all those birds which quit the nest soon after they are hatched, and which are consequently more fully developed at their birth, are very large."[3] It must be added, though, that the number of eggs to be covered at one time seems also to have some relation to their size, and this offers a further explanation of the fact just mentioned with regard to the Snipe and the Partridge—the former being one of those birds which are constant in producing four, and the latter often laying as many as a dozen—for the chicks of each run as soon as they release themselves from the shell.

Incubation. Incubation is performed, as is well known, by the female of nearly all Birds, but with most of the *Passeres* and many others the male seems to share her tedious duties, and among the *Ratitæ*, apparently without exception, the cock takes that office wholly on himself. There are a few groups or perhaps species in which the same practice is suspected to obtain—certain of the *Limicolæ* for instance, the Godwits (*Limosa*), the Phalaropes (*Phalaropus*), and the Dotterel (*Eudromias morinellus*)—and in these it is to be remarked that the hen is larger and more brightly coloured than her mate. Owing to the unfortunate neglect of those who have the opportunity of making the needful observations the period of Incubation has been ascertained in comparatively few birds, and it is here possible to deal with that subject only in the most vague and general language. It may be asserted that most of the smaller *Passeres* of Europe hatch their young in about thirteen days, but in a few species the term is believed to be shortened to ten or eleven days, while in the largest of that Order, the Raven, it is lengthened to some twenty-one days. This also is the period which the Barndoor-fowl ordinarily takes, but the Pheasant, though so very nearly allied, takes about twenty-eight. Most Water-birds, so far as is known, and the smaller Birds-of-prey seem to require as long a time, but in the Swan incubation is protracted to six weeks. The temperature of the air is commonly credited with having something to do either in hastening or retarding exclusion from the egg, but to what extent, or even whether justly so or not, seems in the absence of precise experiments to be doubtful. Certain birds occasionally begin brooding as soon as the first egg is laid,[4] and this plan unquestionably has its advantages, since the offspring being of different ages thereby become less of a burthen on the parents which have to minister to their wants, while the fostering warmth of the earlier chicks can hardly fail to aid the development of those which are unhatched, during the absence of father and mother in search of food; but most birds, and it need scarcely be said, all those the young of which run from their birth, await the completion of the clutch before sitting is begun. The care bestowed, by almost every species, on the infant-brood, is proverbial, and there is hardly any extremity of danger which one at least of the anxious parents will not incur to ward off injury from their progeny.

MOULT.

The more or less protracted business of reproduction being ended there forthwith follows in the case of nearly all Birds a process of the most vital consequence to them. This is the Moult or shedding of their old and often weather-beaten feathers to be replaced by an entirely new suit. It is probably the severest strain to which bird-life is exposed, and, to judge from its effects on our domesticated pets, produces a greater mortality than an occasional want

[1] It is curious that Ostriches' eggs from North Africa are to be readily distinguished from those from the Cape of Good Hope by their smooth ivory-like surface, without any punctures, whereas southern specimens are rough as though pock-marked (*Ibis*, 1860, p. 74), yet no difference that can be deemed specific has as yet been established between the birds of the north and of the south.

[2] A great deal of valuable information on this and other kindred subjects is given by Des Murs, *Traité général d'Oologie ornithologique* (8vo, Paris: 1860).

[3] Hewitson, *op. cit.* Introd. p. x.

[4] This seems to be very often the case with the Owls, but if the writer's observation is not mistaken the habit is not constant even with the same individual bird.

of proper or even any food does. Important however as are its bearings on every individual of the whole Class, the subject is one which has been sadly neglected by ornithological writers and, with one exception,[1] we are not aware of any connected series of observations on Moult within the whole range of their literature. The structure and mode of growth of feathers has been very well studied and described by several investigators, and must be especially treated in introducing the subject of Pterylography—or the disposition of the various plumed patches on the bird's body—which, having been found to be a most useful auxiliary in Classification, is deferred until that comes to be discussed under the article "ORNITHOLOGY." For the present we have briefly to consider the different phases which the process of Moulting offers.

Annual Moult. As a general rule all Birds are subject to an annual Moult, and this as above stated, commonly begins immediately on the close of the breeding-season, but, as will be explained further on, there are some which undergo in addition a second or even a third partial change of plumage, and it is possible that there may be others still more exceptional, our information respecting these, however, is too meagre to make it worth while saying anything here about them. It must be acknowledged that with regard to the great majority of forms we can only judge by analogy, and though it may well be that some interesting deviations from the general rule exist of which we are altogether ignorant, yet when we consider that the *Ratitæ*, so far as observed, moult exactly in the same manner as other birds,[2] the uniformity of the annual change may be almost taken for granted.

Necessity of moult. It is not intended here to describe the way in which a feather dies and a new one succeeds it, nor need we compare the process of moulting with the analogous shedding of the hair in Mammals or of the skin in Reptiles. Enough for our present purpose to see that such renovation is required in Birds, which nearly all have to depend upon their quills for the means of locomotion and hence of livelihood. It is easy to understand that durable as are the flight-feathers, they do not last for ever and are besides very subject to accidental breakage, the consequence of which would be the crippling of the bird. It is obviously to provide against what in most cases would be such a disaster as this last that we find the *remiges*, or quill-feathers of the wings, to be always shed in pairs. They drop out not indeed absolutely at the same moment, though this sometimes seems to happen, but within a few days of each other, and, equilibrium being thus preserved, the power of flight is but slightly deteriorated by their temporary loss. The same may be observed in a less degree, since there is less need of regularity, with the rest of the plumage, as a little attention to any tame bird will show, and the new feathers grow at an almost equal rate. In the young of most species the original quills are not shed during the first year, nor in the young of many does there seem to be an entire moult during that time, but in the typical *Gallinæ*, which are able to fly at a very early age, often before they are one-third grown, the original quills, being proportioned to the duties required of them, are shed before the bird has attained its full size and are succeeded by others that serve it when it has reached maturity. In the Duck-tribe (*Anatidæ*), however, we have a very singular exception to what has been above stated. Most of these birds shed their quill-feathers all at once, and become absolutely incapable of flight for a season,[3] during which time they generally seek the shelter of thick, aquatic herbage, and it is further to be particularly remarked that the males of most of two sections of the family (*Anatinæ* and *Fuligulinæ*) at the same period lose the brilliantly-coloured plumage which commonly distinguishes them and "go into eclipse," as Waterton happily said, putting on for several weeks a dingy garb much resembling that of the other sex, to resume their gay attire only when, their new quills being grown, it can be safely flaunted in the open air. **Additional moult.** Here we have the first instances of Additional Moult to be mentioned. Another is not less interesting, though ornithologists must confess with shame that they have not sufficiently investigated it. This is that of the Ptarmigan (*Lagopus mutus*), both sexes of which not only moult after the breeding-season is over into a grey suit, and then again as autumn passes away into their snowy winter-clothing, but, divesting themselves of this last in spring, then put on each a third and most distinctive dress—these changes, however, do not extend to the quills either of the wings or tail.[4]

Variation of moult in allied birds. The number of Birds which undergo a more or less entire Double Moult is very considerable, and the peculiarity is not always characteristic of families or even, unless in a restricted sense, of Genera. Thus while the Garden-Warbler (*Sylvia salicaria*) is said to moult twice in the year the Blackcap (*S. atricapilla*) does so but once. The same may be said of the *Emberizidæ*, in which family both practices seem to obtain, but on the other hand the distinction in this respect between the Larks (*Alaudidæ*) and the Pipits (*Anthinæ*), belonging to the family *Motacillidæ*, appears, so far as our knowledge goes, to be invariable, though the habits and general appearance of both groups are so much alike—the *Alaudidæ* moulting but once and the *Anthinæ*, conforming to the practice of the normal *Motacillidæ* (*Motacillinæ*), twice a year—the quills, be it understood, excepted. But it would be impossible here to give more than these few examples, and indeed we scarcely know anything of the subject outside of groups belonging to the Northern hemisphere.[5]

Partial moult. In a large number of species the Additional Moult is very partial, being often limited to certain portions of the plumage, and it is yet an unsolved problem how far some of the changes to be observed are due to actual Moult and how far to the alteration of colour in the feathers themselves, as also the way by which this alteration of colour is produced, whether, as certainly happens in many instances, by the dropping off of the "barbicels"—the fine filaments that fringe the "barbicels" which are arranged on the upper surface of each "barb" composing the web of the feather—or in some other manner. With either of these last considerations we need not now concern ourselves. It is unquestionable that there are innumerable species of birds, the males at least of which put forth in spring decorative plumes unknown at any other season, and it would appear that in the majority of them the feathers which before clothed the parts whence the newly-donned ornaments grow are doffed to make room for these paraphernalia of marriage.

The subject of Additional Moult is thus intimately connected with the seasonal adornment of Birds, and as that

[1] This is a valuable paper by Herr Meves, of Stockholm (*Œfvers. K. Vet. Akad. Förhandl.* 1854, p. 258), of which a German translation with some additions by the author may be found in *Journ. für Ornith.* 1855, pp. 230–238.

[2] For the knowledge of this fact the writer is indebted to the vast experience of Mr Bartlett.

[3] One species, *Micropterus cinereus*, seems never to regain the power of flight thus lost. *Cf.* Cunningham, *Proc. Zool. Soc.* 1871, p. 262.

[4] Macgillivray (*Brit. Birds*, i. p. 196, London: 1837; and *Nat. Hist. of Deeside*, p. 405, London: 1855) thought there were *four* moults in this species, but that seems to be one too many. Herr Meves (*loc. cit.*) and the Abbé Caire (*Rev. Zool.* 1854, p. 494) independently made the discovery of the Triple Moult, and almost simultaneously announced it. *Cf.* Gloger, *Journ. für Orn.* 1856, p. 461.

[5] The fullest list as yet published is that of Herr Meves (*ut supra*), but it is not entirely free from error.

properly belongs to a branch of the great question of Natural Selection, its further consideration must here be put off until that is more fully treated, together with what are known as the "Laws of Plumage," the reader being meanwhile referred to those excellent chapters in which Mr Darwin[1] has treated the matter with his usual perspicuity, though even he has far from exhausted its varied points of interest.

It remains to be remarked that though the annual Moult commonly takes place so soon as the breeding-season is over, there are plenty of cases where we find the change delayed to a later period of the year. This is so with the Swallow (*Hirundo rustica*), which has long been known to moult in midwinter, and it is generally the way with all the Diurnal Birds-of-prey. But unquestionably most birds accomplish the change much earlier, and before they leave their breeding-quarters for their winter-haunts, thereby starting on one of their great annual journeys with all the external machinery of flight renewed and in the best condition for escaping its attendant perils. (A. N.)

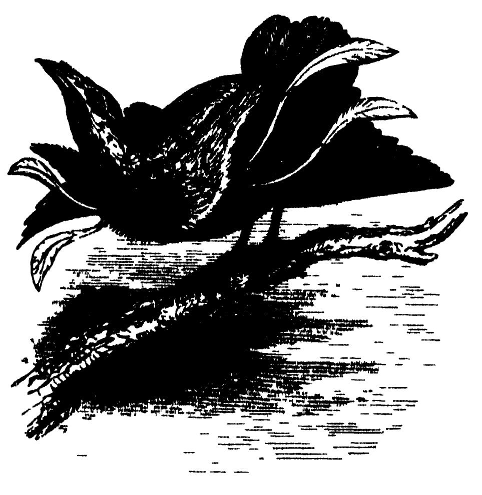
Index to the Genera and Larger Groups of Birds named.

BIRDS OF PARADISE, a group of Passerine Birds inhabiting New Guinea and the adjacent islands, so named by the Dutch voyagers in allusion to the brilliancy of their plumage, and to the current belief that, possessing neither wings nor feet, they passed their lives in the air, sustained on their ample plumes, resting only at long intervals suspended from the branches of lofty trees by the wire-like feathers of the tail, and drawing their food "from the



Standard Wing Bird of Paradise (*Semioptera wallacei*).

dews of heaven and the nectar of flowers." Such stories obtained credence from the fact that so late as the year 1760, when Linnæus named the principal species *apoda*, or "footless," no perfect specimen had been seen in Europe, the natives who sold the skins to coast traders invariably depriving them of feet and wings. The birds now usually included under this name belong to two distinct families, the *Paradiseidæ* and the *Epimachidæ*, the former or true Birds of Paradise being closely allied to the Crows, the latter or Long-billed Paradise Birds being usually classed, from the form and size of their bills, with the Hoopoes. Both families occupy the same geographical area, and are alike distinguished by the enormous development of certain parts of their plumage. Of the true birds of paradise, the largest is the Great Emerald Bird (*Paradisea apoda*), about the size of the common jay. Its head and neck are covered with short thick-set feathers, resembling velvet pile, of a bright straw colour above, and a brilliant emerald green beneath. From under the shoulders on each side springs a dense tuft of golden-orange plumes, about 2 feet in length, which the bird can raise at pleasure, so as to enclose the greater part of its body. The two centre tail feathers attain a length of 34 inches, and, being destitute of webs, have a thin wire-like appearance. This splendid plumage, however, belongs only to the adult males, the females being exceedingly plain birds of a nearly uniform dusky brown colour, and possessing neither plumes nor lengthened tail feathers. The young males at first resemble the females, and it is only after the fourth moulting, according to A. R. Wallace, who recently studied those birds in their native haunts, that they assume the perfect plumage of their sex, which, however, they retain permanently afterwards, and not during the breeding season only as was formerly supposed. At that season the males assemble, in numbers varying from twelve to twenty, on certain trees, and there disport themselves so as to display their magnificent plumes in presence of the females. Wallace in his *Malay Archipelago*, vol. ii., thus describes the attitude of the male birds at one of those "sacaleli," or dancing parties, as the natives call them; "their wings," he says, "are raised vertically over the back, the head is bent down and stretched out, and the long plumes are raised up and expanded till they form two magnificent golden fans striped with deep red at the base, and fading off into the pale brown tint of the finely-divided and softly-waving points; the whole bird is then overshadowed by them, the crouching body, yellow head, and emerald green throat, forming but the foundation and setting to the golden glory which waves above." It is at this season that those birds are chiefly captured. The bird-catcher having found a tree thus selected for a "dancing party," builds a hut among the lower branches in which to conceal himself. As soon as the male birds have begun their graceful antics, he shoots them, one after the other, with blunt arrows, for the purpose of stunning and bringing them to the ground without drawing blood, which would injure their plumage; and so eager are those birds in their courtship that almost all the males are thus brought down before the danger is perceived. The natives in preparing the skins remove both feet and wings, so as to give more prominence to the commercially valuable tuft of plumes. They also remove the

skull, and the skin is then dried in a smoky hut. The Great Emerald Bird, so far as yet known, is only found in the Aru Islands. The Lesser Bird of Paradise (*Paradisea minor*) though smaller in size and somewhat less brilliant in plumage, in other respects closely resembles the preceding species. It is also more common, and much more widely distributed, being found throughout New Guinea and the neighbouring islands. Its plumes are those most generally used as ornaments for ladies' head-dresses. It has been brought alive to Europe, and has been known to live for two years in the gardens of the Zoological Society of London. Both species are omnivorous, feeding voraciously on fruits and insects. They are strong, active birds, and are believed to be polygamous. The King Bird of Paradise (*Cicinnurus regius*) is one of the smallest and most brilliant of the group, and is specially distinguished by its two middle tail feathers, the ends of which alone are webbed, and coiled into a beautiful spiral disc of a lovely emerald green. In the Red Bird of Paradise (*Paradisea rubra*) the same feathers are greatly elongated and destitute of webs, but differ from those in the other species, in being flattened out like ribbons. They are only found in the small island of Waigiou off the coast of New Guinea. Of the Long-billed Paradise Birds (*Epimachidæ*) the most remarkable is that known as the "Twelve-wired" (*Seleucides alba*), its delicate yellow plumes, twelve of which are transformed into wire-like bristles nearly a foot long, affording a striking contrast to the dark metallic tints of the rest of its plumage. Like the *Paradiseidæ* they feed on insects and fruits.

BIRKBECK, George, an English physician and philanthropist, born at Settle in Yorkshire in 1776. He early evinced a strong predilection for scientific pursuits; and in 1799, after graduating as doctor of medicine, he was appointed to the chair of natural philosophy at the Andersonian Institution of Glasgow. In the following year he delivered, for the benefit of the working-classes, a gratuitous course of scientific lectures, which were continued during the two following years and proved eminently successful. He removed to London in 1804, and there he endeavoured to prosecute his philanthropic schemes, at first without much encouragement, but ultimately with marked success. In 1827 he contributed to found the Mechanics' Institute, his coadjutors being Bentham, Wilkie, Cobbett, and others. He was appointed director of the institute, which he had originally endowed with the sum of £3700, and held the office till his death in December 1841.

BIRKENHEAD, a seaport, market-town, extra-parochial district, township, and parliamentary borough, in the hundred of Wirral and west division of Cheshire, England. It is situated on the western bank of the Mersey, directly opposite Liverpool. It is of considerable antiquity, its history dating from 1150, when a priory was founded in honour of St Mary and St James by the third baron of Dunham Massey, and had considerable endowments. The prior sat in the parliaments of the earls of Chester, and enjoyed all the dignities and privileges of palatinate barons. A fine crypt and some interesting ruins of the priory still exist. From a comparatively obscure fishing village Birkenhead has become a large and important town, with a rapidity truly marvellous. The inhabitants numbered only 200 in 1821; in 1831 they were 2569; the following table shows the increase since 1841:—

Year.	Population.	Dwelling Houses.	Rateable Value.
1841	8227	1466	£44,000
1851	25,000	4148	114,301
1861	37,796	5239	150,827
1871	45,418	7511	219,011
1875	(estim.) 52,000	8000	228,909

Birkenhead began to develop itself as a market-town in the year 1833, when an Act was obtained for paving, lighting, watching, cleansing, and improving the town, and for regulating the police and establishing a market. By this Act the Improvement Commissioners were originally constituted, and at that time included the mayor, bailiffs, and four aldermen of Liverpool. Immediately after the passing of this Act the town made rapid progress. The principal streets were laid out on a regular plan, intersecting each other at right angles. A line of tramway, the first laid in England, affords every facility of street communication. Hamilton Square, which occupies the summit of the rising ground near the river, forms the basis or starting point for all the parallel and rectangular lines of streets. The houses of the square are four stories in height, with stone fronts, the centres and ends of each terrace being relieved or ornamented with columns and porticos in the Tuscan order of architecture

Birkenhead has (exclusive of the out townships) nine churches belonging to the Established Church. St Mary's, built in 1821 by Mr F. R. Price, late lord of the manor, is in the Decorated Gothic style of architecture, with a well-proportioned tower and spire. The churchyard includes the burial ground and ruins of the ancient priory and chapel of St Mary. In addition to the Established churches there are twenty-four places of worship belonging to various Nonconforming denominations, viz., five Presbyterian, three Independent or Congregational, two Baptist, four Wesleyan, one Primitive Methodist, one Society of Friends, two Plymouth Brethren, three Roman Catholic, one Catholic and Apostolic, two Unitarian. Many of these buildings are fair examples of Gothic and classic architecture. St Aidan's Theological College, in connection with the Established Church, occupies a fine and elevated site adjoining the western boundary of Claughton. It is a handsome building in the Tudor style of architecture. There are seven public elementary schools in connection with the Established churches, and seven in connection with other religious bodies. There is also a first-class proprietary school, conducted on the model of the great public schools, besides several private academies.

There are several public buildings in Birkenhead worthy of notice. The market-hall is a large and commodious building, 430 feet long and 130 feet wide, with substantial and lofty vaults extending under its entire area. It was opened in 1845, and built at a cost of £35,000. The public slaughter-houses in Jackson Street, belonging to the Birkenhead Commissioners, form an extensive pile of buildings; they were erected in 1846 at a cost, exclusive of the site, of about £11,000, and were the first public slaughter-houses of any extent erected in England. The town water-works also belong to the Birkenhead Commissioners, and consist of two pumping stations, the wells of which yield an aggregate supply of about 2½ million gallons in twenty-four hours. The town-hall in Hamilton Street is a one-story building, and formed when first erected the front of the old market-hall; it contains a police court, fire-engine station, and chief bridewell; there are, besides, two branch bridewells. Among other buildings are the post-office in Conway Street, the borough hospital, and the School of Art, also in Conway Street, both erected by the late Mr John Laird, M.P., and a free library in Hamilton Street. The large and commodious industrial schools in Corporation Road were built at the cost of Sir Wm. Jackson, Bart., as a memorial to the late Prince Consort. The Music Hall and the Queen's Hall are situated in Claughton Road. There is also a neat and commodious theatre and opera-house in Argyle Street.

Birkenhead Park, opened in 1847, occupies 190½ acres of ground, and was laid out at a cost (including the land) of

£140,000. Birkenhead Cemetery, on Flaybrick Hill, occupies 20½ acres of ground, and cost about £40,000.

Woodside Ferry may be regarded as the principal entrance to Birkenhead and Wirral from Liverpool; and its exclusive right of ferryage dates back to 1332. In 1842 the Birkenhead Commissioners purchased this ferry, under an Act of Parliament, from Mr F. R. Price, the lord of the manor. At the present time the annual receipts for passengers alone amount to £36,000, and the number of persons conveyed in the twelve months is upwards of nine millions, the single fare being one penny. A large landing-stage, 800 feet in length and 80 feet in width, is moored at this ferry, the passenger traffic being conducted to and from the stage by means of a double gangway bridge, covered by two circular glass and iron roofs. The goods traffic is conveyed to and from the stage by a well-constructed floating bridge, 670 feet in length and 30 feet in width, which enables the traffic to be carried on at any state of the tide. Handsome and commodious saloon steamers, built and designed upon an improved principle, and capable of carrying above 1700 passengers each, are now used upon this ferry. The late Mr William Laird, whose name is so well known in connection with iron shipbuilding, first conceived the idea of turning to advantage the capabilities of Wallasey Pool for the formation of a dock. After a lapse of many years, the Commissioners of Birkenhead, alive to the advantages which this project would confer upon the town, employed the late Mr Rendel as their engineer, and applied to Parliament for powers to construct the necessary works. The foundation-stone of the new docks was laid in October 1844, and the first dock was opened by the late Lord Morpeth on 5th April 1847. Subsequently, the dock powers of the Commissioners were entrusted to a corporate body of trustees who afterwards transferred the property to the corporation of Liverpool; and ultimately it was vested in the Mersey Docks and Harbour Board, a corporation created by the Act of 1857 for the management of the docks on both sides of the Mersey. At that time the area of the dock space open and in use in Birkenhead was about 7 acres.

The docks bound the town on the north and north-east and partly on the east, extending from the landing-stage at Woodside Ferry to the Wallasey Bridge, a distance of over two miles. The Great Float has been constructed on the site of the Wallasey Pool, forming an immense dock of 150 acres, with a quay space of about five miles. The Great Float separates Birkenhead from Poulton-cum-Seacombe, in the parish of Wallasey, and communicates on the east with a low water basin of about 14 acres (now being converted into a dock) and the Alfred Dock (about 8 acres, and quay space 460 lineal yards), and on the south-east with the Egerton, Morpeth, and Morpeth Branch Docks. The Morpeth Dock (about 11 acres, quay space 1299 lineal yards) is connected with the Morpeth Branch Dock (about 8½ acres, quay space 600 lineal yards), both set apart for steamers. The total water area of these docks is about 170 acres, and the lineal quay space about 10 miles.

The entrances to the Birkenhead Docks are capable of docking the largest class of steamers afloat. The massive iron bridges across the dock entrances are opened and closed by hydraulic power, which is likewise applied to the cranes, coal hoists, warehouse lifts, and other appliances about the docks. At the extreme western end of the West Float are three large graving docks, two about 750 feet in length, and 130 feet and 80 feet in width respectively, and the largest, now in course of construction, measuring about 900 feet in length and 130 feet in width.

Substantial and commodious sheds and warehouses have been erected at various places along the dock quays for the full development of the traffic.

The block of warehouses known by the name of the corn warehouses are immense piles of buildings, with a canal between to give access to the separate blocks of buildings, and with machinery for carrying the grain, &c., from floor to floor, and for despatching it by railway.

In 1847 the Birkenhead Dock Warehousing Company opened their first warehouses, capable of storing 80,000 tons of goods. Each block is detached, and the whole premises are surrounded by a wall 12 feet high. A railway branch, called the Dock Extension Railway, is carried round the property. The company also built blocks of houses for their workmen, known as the Dock Cottages. This property is now in the hands of the Mersey Docks and Harbour Board.

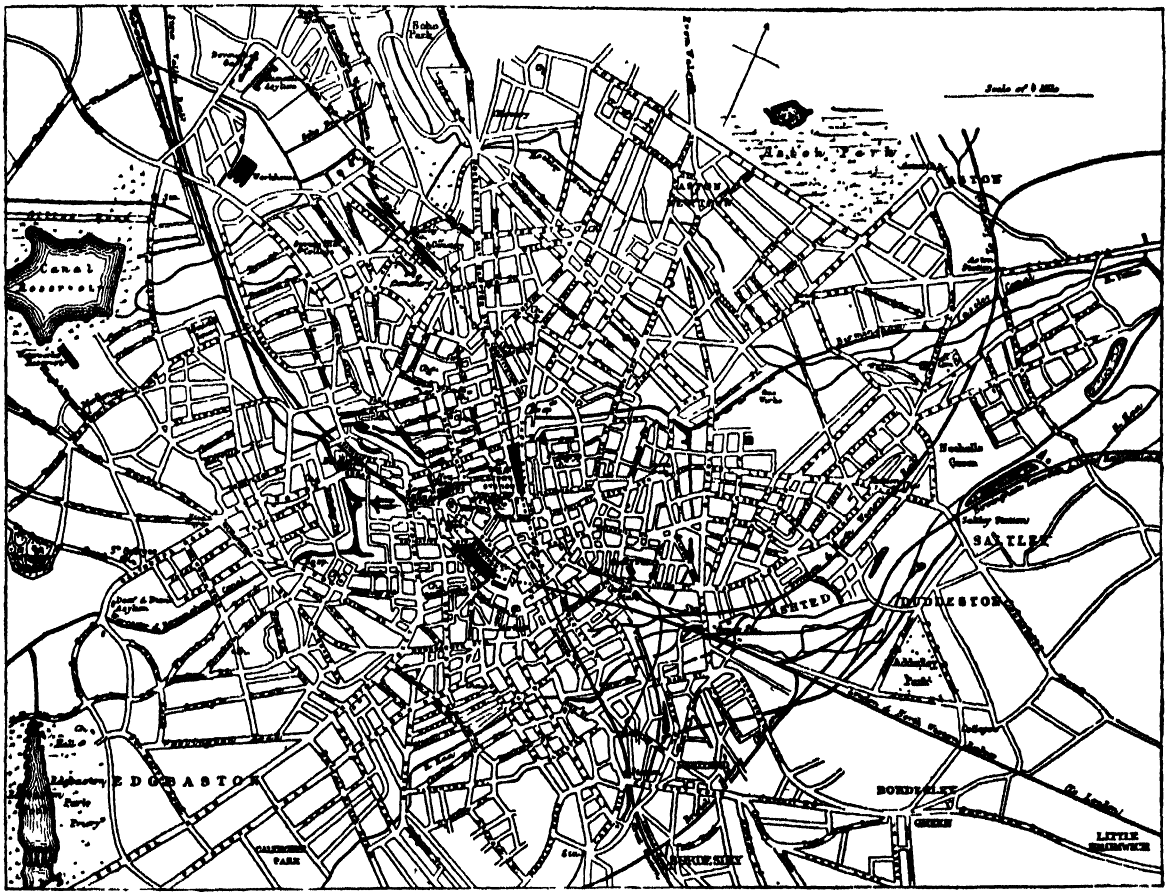
The commerce of Birkenhead is in all respects a branch of that of Liverpool, and chiefly devoted to coal, guano, and grain,—the quantity of coal alone exported being over one million tons per annum. Many manufactories have sprung up within the last few years on the margin of the Great Float and other parts of the town, such as iron foundries, boiler-works, oilcake and seed mills, &c., some of the engineering works, shipbuilding yards, and forges being on a large scale. The Birkenhead Iron-works of Messrs Laird Brothers employ from 3000 to 4000 men; these works in connection with their shipbuilding yards, have turned out some of the largest iron-clad ships; the engine-works, also belonging to the same firm, are on a very extensive scale. The Canada Works, belonging to Messrs Thomas Brassey and Co., carry on an extensive business in marine engines, iron-bridge building, pontoon and general railway work. There are also the Britannia Works (Messrs James Taylor and Co.) for portable engines, marine engines, traction engines, steam cranes, &c.; Messrs Clay and Inman's Forge, for heavy shafting, &c.; the Wirral Foundry, for large engine castings, &c.; and the Starbuck Car and Waggon Co.'s Works, for building tramway cars, &c.; and Messrs Clover and Clayton's shipbuilding premises as well as other manufactories of less extent.

The affairs of the township of Birkenhead and Claughton-cum-Grange are managed by twenty-one Commissioners, chosen by the ratepayers. The town contains a head post-office, county court, police court, petty sessional court for the hundred of Wirral, and two banks. Two newspapers are published weekly. The principal market-day is Saturday, but a large hay, straw, and vegetable market is held on Tuesdays in the hay market, a large open space of ground, having an area of about 1½ acres. The total area of the Commissioners' district is 1684 acres, including 365 acres of water space, viz., Birkenhead, 1248 acres, and Claughton-cum-Grange, 436. The parliamentary borough of Birkenhead was constituted in 1861, and returns one member to parliament. Its parliamentary limits include the extra-parochial chapelry of Birkenhead, the several "townships of Claughton, Tranmere, and Oxton, and so much of the township of Higher Bebington as lies to the eastward of the road leading from Higher Tranmere to Lower Bebington." The population of this district in 1861 was 51,649, and in 1871 it had increased to 64,671.

BIRMINGHAM, the fourth town in size and population in England, and the fifth in the United Kingdom, is situated at the extreme north-west of the county of Warwick, in 52° 59′ N. lat. and 1° 18′ W. long. It is 102 miles in a straight line N.W. of London, from which it is distant 112 miles by the North-Western Railway. The Roman Road, known as the Ikenield Street, runs through the town. On the north Birmingham touches Staffordshire, and on the south and west Worcestershire, the suburbs of the town extending largely into both these counties—Harborne and Handsworth being in the former and Balsall,

Moseley, and Yardley in the latter. The borough itself, however—both parliamentary and municipal, the boundaries being identical—is wholly in the county of Warwick. It covers an area of 8420 acres (of which 5900 are built upon), and includes the whole of the parishes of Birmingham and Edgbaston, and about one-third of the parish of Aston. It is nearly 6 miles long, has an average breadth of 3 miles, is 21 miles in circumference, and has 190 miles of streets and roads. The population, at the census of 1871, was 343,000; and in June 1875 it was estimated by the registrar-general at 360,000. Birmingham was enfranchised by the Reform Act of 1832, when two representatives were assigned to it—and Mr Thomas Attwood and Mr Joshua Scholefield (leaders of the Political Union) were elected; by the Reform Act of 1867 this number was raised to three. A grant of incorporation was made to the town in 1838, when the first municipal council was elected. In 1870 a School Board of fifteen members was elected, under the Elementary Education Act passed in that year.

The town is built upon the New Red Sandstone, on a boldly undulated site, varying from 200 to 600 feet above the sea-level, steadily rising towards the north and west, so that when looked at from the heights on the south-east side it presents the appearance of a vast semicircle, picturesquely disposed, the masses of houses being broken by spires and lofty chimneys, and the south and west sides being thickly wooded on the slopes. The plan of the town is irregular, and the streets are mostly winding, and many of them somewhat narrow. In the centre, however, is a large open space, known as the Bull Ring and High



Sketch-Plan of Birmingham.

Street, at the foot of which stands the mother church of St Martin, and in which is situated the Market-Hall, one of the largest buildings of its kind in the kingdom. From this centre access is obtained to the principal streets, New Street and High Street; the former, about a quarter of a mile in length, derives a most picturesque appearance from its slightly curved form, and from the effective manner in which the sky-line is broken by lofty buildings alternating with others of lower altitude. This street contains the Exchange, the Grammar School, the Theatre Royal, the rooms of the Royal Society of Artists, which have a fine Corinthian portico stretching across the pavement. At the upper end of the street is the Town-Hall, and close to this are the corporate buildings and the Post-Office. The last quarter of a century has seen a great advancement in the style and accommodation of the public and commercial edifices; streets have been widened and new roads opened, and the place has altogether put on a livelier and wealthier look. Excepting in some of the older and poorer districts, the private houses have undergone a corresponding improvement. The richer classes live chiefly in the parish of Edgbaston, which belongs almost entirely to Lord Calthorpe, and in which strict rules as to the description, position, and area of the houses are enforced. The streets inhabited by the working-classes are, of course, more crowded, and many of the houses are built in enclosed courts, access to which is gained from the street, either by openings between the houses, or by narrow entries, too commonly built over, and thus impeding the free passage of air. Many of the courts, however, are wide enough to allow of small gardens in front of the houses, while in the suburbs almost every house is provided with a garden of some kind; and in a considerable number of cases the houses, through means of building societies, have become

the property of the workmen themselves. The habit exists among all classes of each family (with rare exceptions) occupying a separate house, a practice which greatly affects the area of the town. Thus, to a population of 360,000 there are about 76,000 inhabited houses, giving an average of five persons to a house. Birmingham is a town of rapid growth. In 1700 the population was about 15,000. A century later, at the census of 1801, it had increased to 73,000. In the next thirty years the population doubled, being 147,000 in 1831. The same process was repeated in the following term of thirty years, the population in 1861 being 296,000. Between 1861 and 1871 the increase was 47,000, and the returns of the registrar-general show that the same rate of progress is still going on. It is, however, likely to be checked by the increasing value of land within the borough, by the absorption of available sites for building, and by the consequent overflow of population into the suburbs. If these, inhabited solely by borough people, are taken into account, the real population at present is probably not far short of half a million.

Government.—The government of the town resided originally in the high and low bailiffs, both officers chosen at the court of the lord of the manor, and acting as his deputies. The system was a loose one, but by degrees it became somewhat organized, and Crown writs were addressed to the bailiffs. In 1832, when the town was enfranchised, they were made the returning officers. About the begi. ning of the century, however, a more regular system was instituted, by an Act creating a body of street Commissioners, who acted for the parish of Birmingham,—the hamlets outside its boundaries having similar boards of their own. The annoyance and difficulty caused by these bodies—thirteen in number—led to a demand for the incorporation of Birmingham as a borough; and a charter was accordingly granted by the Crown in 1838, vesting the general government in a mayor, sixteen aldermen, and forty-seven councillors. The powers of this body were, however, unusually restricted, the other local governing bodies remaining in existence. It was not until 1851 that an Act of Parliament was obtained, abolishing all governing authorities excepting the Town Council, and transferring all powers to this body. Under this Act, and another local Act obtained in 1862, the affairs of the town are now administered, the whole municipal government being in the hands of the Town Council. The importance of the duties discharged by the Council may be inferred from the fact that it has under its control nearly 200 miles of street and road, that it has a police force of nearly 500 men, and that its revenue, derived from tolls and rates. amounts to about £300,000 a year. These responsibilities have been increased by the purchase in 1875 of the gas and water-works (the latter with a daily supply of 17,000,000 gallons), the two purchases making a cost of more than £3,000,000. The growth of the revenue and expenditure of the town, its rateable value, and its ordinary debt, excluding the gas and water-works, will be seen from the following tabular statement:—

Year.	Amount of Assessment to the Borough Rate.	Total Amount of Rate in the £	Income.	Expenditure.	Balance of Public debt.
	£	s. d.	£	£	£
1854	645,349	3 5	120,237	131,723	366,095
1859	824,869	3 4	157,121	136,987	467,002

N.B.—The amount of property possessed by the Corporation on 31st December 1874, taken at its original cost, was £1,259,047.

[1] Including rate for School Board. 3d. in the £.

The administration of the poor-law is vested in a Board of Guardians, of sixty members, for the parish of Birmingham. The parish of Edgbaston (wholly within the borough) is in the poor-law union of King's Norton, and that part of the parish of Aston included in the borough is in the Aston Union. There are three workhouses—that for Birmingham parish, situated at Birmingham Heath, is capable of receiving over 2000 inmates. In the week ending June 19, 1875, there were chargeable to the parish (including lunatics and persons receiving outdoor relief) 6949 paupers, a very small number in proportion to population.

Arms of Birmingham.

Birmingham has a grant of quarter sessions, with a recorder, and petty sessions are held daily at the Sessions Court, in Moor Street, before a stipendiary magistrate, and a bench of borough justices. The justices for the borough and Aston division of Warwickshire also sit here occasionally. The borough justices have charge of the administration of the gaol. The town is the head of a county court district, and is the seat of the probate registry for Warwickshire.

Religious Denominations, Buildings, &c.—Until the year 1821 Birmingham was in the diocese of Lichfield and Coventry; it is now in the diocese of Worcester and archdeaconry of Coventry, and is a rural deanery. There was formerly a religious house, the priory of St Thomas the Apostle, and a Guild of the Holy Cross, an association partly religious and partly charitable, having a chantry in the parish church. The possessions of the priory went to the Crown at the dissolution, and the building was destroyed before the close of the 16th century. The lands of the Guild of the Holy Cross were granted by Edward VI. to trustees for the support of a free grammar school; they are now of the value of nearly £15,000 a year. Until 1715 there was but one parish church, St Martin's, a rectory, having the tithes of the entire parish of Birmingham. St Martin's was erected about the middle of the 13th century; but in the course of ages was so disfigured, internally and externally, as to present no traces except in the tower and spire of its former character. In 1853 the tower was found to be in a dangerous condition, and together with the spire was rebuilt. In 1873 the remaining part of the old church was removed without disturbing the monuments, and a new and larger edifice was erected in its place, at a cost of nearly £30,000. The new church constitutes the chief ecclesiastical edifice in Birmingham, and indeed the handsomest structure in the town. St Philip's, a stately Italian structure, designed by Archer, a pupil of Wren, was the next church erected. It was consecrated in 1715. Then followed St Bartholomew's in 1749, St Mary's in 1774, St Paul's in 1779, St James's, Ashted, in 1791, and others, which need not be mentioned, followed in due course. At present the mother parish is divided into five rectories, and there are within the borough, including those mentioned, 42 churches (each having an ecclesiastical district assigned to it) of the Church of England, most of these having schools and missions attached to them.

Under the Commonwealth Birmingham was a stronghold of Puritanism. Clarendon speaks of it and the neighbourhood as "the most eminently corrupted of any in England." Baxter, on the other hand, commending the garrison of Coventry, says it contained "the most religious men of the parts round about, especially from Birmingham." The traditional reputation for Nonconformity is maintained by the town, all varieties of dissenters being numerous and influential.

The *Unitarians*, the oldest body established here, have six chapels. One of these, the Old Meeting, is historically interesting, the congregation having been formed on the Presbyterian model by a number of ministers ejected under the Act of Uniformity. Another chapel, the New Meeting, in Moor Street (now occupied by the Roman Catholics), is memorable as having been the place of Dr Priestley's ministerial labours. In 1862 the Unitarians removed from this place to a new Gothic edifice, called the Church of the Messiah, in Broad Street, where they still preserve a monument of Priestley, with a medallion portrait in profile, and an inscription written by Priestley's friend, Dr Parr. The *Society of Friends*, whose first meeting-house dates from about 1690, have now three places of meeting. The *Independents* have now eleven chapels, several of them large and flourishing. The *Baptists* first erected a chapel in Cannon Street in 1738. They have now 16; one of them, Wycliffe Chapel, Bristol Road, is a singularly handsome structure of 14th century Gothic. The *Wesleyan Methodists* were established in Birmingham by John Wesley himself in 1745, when he was roughly handled while preaching on Gosta Green. For some years they

worshipped in temporary premises. They have now 17 places of worship; and the other divisions of the Methodist body have 24 in the aggregate. The *Presbyterians* possess 5 places of worship, and the *Jews* have a handsome synagogue. The *Roman Catholics* have paid special attention to Birmingham. From the Revolution of 1688 until 1789 they had no place of worship here. They now have a bishop (who assumes a title from the town), a cathedral, and 9 other churches or chapels, a cemetery, and other establishments in the suburbs, including several religious houses, including the Oratory, founded by Dr Newman. The principal edifice is the cathedral of St Chad, built from the designs of Mr Pugin, at a cost of more than £30,000.

The religious institutions and societies in Birmingham are very numerous, and with these are associated many establishments of a benevolent character, such as almshouses, asylums, refuges, societies for the aid of discharged prisoners, and for the promotion of religious education in Board schools, training institutions for nurses and servants, and others of various kinds, in the management of which persons of different religious opinions are commonly found working together in friendly association.

Charities.—These are numerous. The principal is the General Hospital, Summer Lane, opened in 1779; it was founded by Dr Ash, an eminent local physician. The yearly average of in-patients is about 2300, of out-patients, 25,000. The Queen's Hospital, Bath Row, the other large hospital of the town, was founded in 1840 by Mr W. Sands Cox, F.R.S., an eminent local surgeon, who also founded the Queen's College as a medical school. This hospital receives annually about 1300 in-patients and 17,000 out-patients. The General Dispensary, the officers of which visit patients at their own homes, relieves about 8000 yearly. The Children's Hospital (free), established in 1864 by Dr Heslop, relieves about 15,000 out and 1000 in-patients. It has two establishments—for out-patients (a very handsome Gothic building) in Steelhouse Lane, and an in-patient department in Broad Street. There is also a Women's Hospital (free) for the special diseases of women; a lying-in charity; special hospitals for diseases of the eye, the ear, bodily deformities, and the teeth; and a homœopathic hospital. The parish of Birmingham maintains a large infirmary at the workhouse (Birmingham Heath), and a dispensary for out-patients in Paradise Street.

Nearly all these medical charities depend upon subscriptions, donations, legacies, and income from invested property; and the sum raised in this way is probably nearly £30,000 a year. There are two public organizations for aiding the charities, both of which were begun in Birmingham. One is a simultaneous collection in October in churches and chapels, called the Hospital Sunday, established in 1859, and now yielding over £5000 a year; the other is the Saturday Hospital collection, made by the work-people in March, which was established in 1873, and yields about £4000.

There is also a Sanatorium at Blackwell, near the Lickey Hill, about 10 miles distant, common to all the hospitals. Amongst the non-medical charities the principal are the Blind Institution and the Deaf and Dumb Asylum, both at Edgbaston; and Sir Josiah Mason's Orphanage at Erdington, which receives 300 orphan children, and was built and endowed at the cost of about £250,000 solely by Sir Josiah Mason, a Birmingham penmaker. There are also in the town numerous almshouses for aged persons, the chief of which are Lench's Trust, the James Charities, the Licensed Victuallers' Asylum. Besides the general benefit societies, such as the Oddfellows', Foresters', &c., which are strongly supported in Birmingham, the work-people have numerous clubs of a charitable kind, and there are several important local provident societies of a general character, with many thousand members.

Education.—The oldest and principal institution is the Grammar School of King Edward the Sixth, founded in 1552, out of the lands of the Guild of the Holy Cross, then of the annual value of £21, but now yielding about £15,000 a year, with a prospect of large increase. The principal or high school, in New Street, was erected in 1840, in the Perpendicular period of the Gothic style, from designs by Sir Charles Barry, at a cost, including land, of £71,000. This school is divided into two departments, classical and English, and educates about 600 boys; while connected with it there are four elementary schools for boys and girls, used chiefly by the lower middle class, the number of pupils being 1500. The classical school has ten exhibitions of £50 each, tenable at Oxford or Cambridge. The next most important foundation is that of the Midland Institute, which includes a general literary department (lectures, museums, and reading-rooms), and an industrial department, with classes in science, languages, mathematics, arithmetic, history, literature, and the laws of health. There are about 600 science students, and about 1600 in the other departments. The Queen's College, originally a school of medicine, founded in 1828, obtained a royal charter in 1843 as a kind of university, with departments of literature, theology, law, science, and engineering. All these branches have now fallen into disuse, excepting medicine and theology; in the latter the college educates candidates for the ministry of the Church of England. An important foundation is Sir Josiah Mason's Scientific College, for the endowment of which Sir Josiah has conveyed to trustees property valued at nearly £100,000, and a capacious building, estimated to cost probably £40,000, is now in erection in Edmund Street, near the Town-Hall. Among the other educational foundations may be mentioned Spring Hill College, Moseley, for the education of Congregational ministers; four industrial schools; a large reformatory for boys at Saltley, and one for girls at Smethwick. For general education there are many private schools, of a good class, for boys and girls. Elementary education is provided in the Church of England day schools, Roman Catholic schools, and Board schools. A total provision, in all the public elementary schools, is made for 41,791 children; there are (July 1875) 51,334 on the books, with an average attendance for the previous quarter of 37,894. The School Board, though it was elected only in 1870, has, by the provision of new schools, and the exercise of compulsory powers, more than doubled the school attendance. It has already built and opened 9 schools, with accommodation for 8800 children, at a cost, for land and buildings, of about £86,000; and 8 other schools are now in progress, providing accommodation for 7400 children, at an estimated cost of about £103,000—making a total expenditure of nearly £200,000, and provision for a total of about 16,000 children.

Libraries, &c.—The principal libraries of the town are the Birmingham Library (belonging to a body of proprietors), founded in 1798 by Dr Priestley, and containing about 40,000 volumes, and the Corporation Free Libraries, in Ratcliff Place, commenced in 1861. These consist of a central reference library and lending library (the former containing 36,000 volumes of carefully chosen books), to which is attached a central reading-room. There are also four lending libraries and news-rooms in other parts of the town, and news-rooms are about to be opened by the Corporation in connection with the Board schools. The total issue of books from the libraries for 1874 was 521,991. Included in the reference library are a special Shakespeare library, containing almost all known editions of the plays and of works illustrating them; a library of nearly 1000 volumes, illustrating the works of Cervantes (presented by Mr W. Bragge of Sheffield); and a large and unique collection of Warwickshire books and antiquities, known as the Staunton collection. An Art Gallery and Industrial Museum is attached to the Free Libraries; and there is at Aston Hall another museum of natural history, &c., belonging to the Corporation. Art instruction is provided by the Royal Society of Artists, which has classes and lectures for students, and which holds two general exhibitions annually; and by the School of Art, which has 900 students, together with affiliated classes in schools, containing nearly 1700 students.

Miscellaneous Institutions, Parks, &c.—These include 8 banks, 4 principal clubs—the Union, the Midland, the Arts, and the Conservative—to which a Liberal Club is about to be added. There are 3 morning and 2 evening daily papers—4 of them Liberal and 1 Conservative—and 2 weekly papers. There are two theatres, 2 large music-halls, and several smaller ones. Musical festivals for the benefit of the General Hospital are held triennially, and are usually marked by the production of new and important works, and by the engagement of most of the leading

vocalists and instrumental performers. There are 5 parks and pleasure grounds belonging to the Corporation—Aston Park and Hall, 45 acres; Calthorpe Park, about 35 acres; Cannon Hill Park, 65 acres; and Adderley and Highgate Parks, each about 12 acres. Besides these there are numerous pleasure-grounds—the Botanical Gardens, Edgbaston, open to subscribers, and the Lower Grounds, a beautiful series of gardens at Aston, in which important flower shows are periodically held. Sutton Park, about 8 miles distant, and including about 3000 acres, is also much used by the Birmingham people. The Corporation has several sets of baths and wash-houses in various parts of the town. There are several extensive cemeteries.

Public Buildings.—Of these the Town-Hall, a nobly-proportioned and impressive edifice, is the principal. It stands at the top of New Street, and on three sides is isolated from all other buildings by broad and handsome streets. The hall, completed in 1850 at a total cost of £52,000, is severely classic, modelled upon a Greek temple. The lower stage consists of a vast plinth or basement, 23 feet high, upon which is reared a façade of peripteral character, with 8 Corinthian columns (36 feet high) at the two principal fronts, and 13 columns on each side. These columns (imitated from those of the temple of Jupiter Stator at Rome) support a bold and enriched cornice, finished at each end with a lofty pediment and entablature. The exterior of the hall is built of Anglesea marble. The interior consists chiefly of a regularly-built room, designed specially for meetings and concerts, with an orchestra containing one of the finest organs in the kingdom. The seats are arranged for an audience of 2265 persons, but when cleared of benches, as is the case at great political meetings, 5000 persons may find standing room. On one side of the Town-Hall are the buildings of the Midland Institute and the Free Libraries (of Italian design), occupying the whole of Ratcliff Place, with fronts to Paradise Street and Edmund Street. A new Art Gallery is in course of erection, fronting the latter street. At the back of the Town-Hall is the site of the new building of the Mason College (Gothic), and in front of the hall, in Paradise Street, are Christ Church (classic), the Queen's College (Gothic), and the Post-Office. On the side of the hall in Ann Street, opposite to the Midland Institute, are the new Corporate Buildings (Italian), now being erected at a cost of nearly £200,000. These will give accommodation for the Town Council, law courts, public offices, and the mayor of the borough. Lower down New Street is the building of the Royal Society of Artists (classic), with a noble portico; then comes the Exchange (Gothic) in Stephenson Place; and at the bottom of the latter street is the Central Railway station, used by the North-Western, the Midland, and their branch railways, and fronted by the Queen's Hotel. The station is more than a quarter of a mile in length. The roof, a magnificent specimen of engineering, consists of a vast arch of glass and iron, carried on pillars on each side, and measuring 1100 feet in length, 80 feet in height, and 212 feet in width in a single span. The glass in the roof weighs 115 tons, and the iron work 1400 tons. Below the station, in New Street, is the Grammar School; and in High Street, close at hand, is the Market Hall, a magnificent classic building, erected in 1833 at a cost of nearly £70,000, with an area of 4380 square yards, and affording room for 600 stalls. Amongst the other public buildings are the Borough Gaol at Winson Green, with 467 cells, arranged on the separate system; near this the Lunatic Asylum, with accommodation for 600 patients: and close at hand the workhouse, which receives about 2000 inmates. The General and Queen's Hospitals are also handsome buildings, the latter especially so, it being remarkable for a very noble out-patient hall. This and the out-patient hall at the Children's Hospital in Steelhouse Lane (Gothic) are perhaps the finest rooms of their kind in the kingdom.

Birmingham had till very recently only one public monument, the statue of Nelson, by Westmacott, in High Street; but several others have been erected—namely, those of Joseph Sturge, at the Five Ways, and of Thomas Attwood, the founder of the Political Union, in Stephenson Place, both of them by the late Mr. Thomas; James Watt, a singularly beautiful work, in Ratcliff Place, by the late Mr Munro; Sir Robert Peel, in New Street, by Mr P. Hollins; the late Prince-Consort, in the Art Gallery, by Mr Foley; Sir Rowland Hill, in the hall of the Post-Office, by Mr Noble; and Dr Priestley, in New Street, by Mr. F. J. Williamson. Chantrey's famous statue of James Watt is in a special chapel at Handsworth church.

Manufactures.—From an early period Birmingham has been a seat of manufactures in metal. Hutton, the historian of the town, claims for it Saxon, or even British antiquity in this respect, but without the shadow of foundation. The first or direct mention of Birmingham trades is to be found in Leland's *Itinerary* (1538). He writes:—"I came through a pretty street as ever I entered into Bermingham towne. This street, as I remember, is called Dirtey (Deritend). In it dwell smiths and cutlers. There be many smithes in the towne that use to make knives and all manner of cutlery tooles, and many lorimers that make bittes, and a great many naylors, so that a great part of the towne is maintained by smithes, who have their iron and sea-cole out of Staffordshire." The cutlers no longer exist, this trade having gone to Sheffield; but the smiths remain, and the heavier cutting tools are still largely made here. The well-ascertained importance of Birmingham as a centre of manufactures began towards the close of the 17th century, one great source of it being the absolute freedom of the town, there being no guilds, companies, or restrictions of any kind; besides which the easy access to cheap coal and iron indirectly helped the development. It is remarkable that two important trades, now located elsewhere, were first established here. Steel was made in Birmingham until 1797, and was then disused for quite 70 years, when an experiment in steel-making (still carried on) was made by a single firm. Cotton-spinning was begun in Birmingham by John Wyatt, and Lewis Paul, and Thomas Warren as early as 1730; but the speculation was abandoned before the end of the century. The great staple of Birmingham is metal-working in all its various forms. The chief variety is the brass-working trade, which employs several hundred masters, and about 10,000 work-people, and consumes probably 50,000 tons of metal annually, which is worked up into an infinity of articles of ornament and utility. Iron-working, though largely carried on, is a much less important trade, works of this kind being chiefly established in the Staffordshire district. Jewellery, gold, silver, and gilt come next to brass. Then follow small arms of all kinds, some of the larger establishments being capable of turning out 2000 stand per week. Buttons, hooks and eyes, pins, and other articles used for dress, constitute a large class of manufactures. Glass, especially table glass, is a renowned staple of the town. Screws, nails, &c., are made in enormous quantities; indeed, Birmingham has a monopoly of the English screw trade. Steel pens are also a specialty—as much as, probably, 15 tons or more of steel being the weekly consumption of these articles; the largest maker, Sir Josiah Mason, rolls 5 tons weekly for his own consumption, and has about 60 tons of pens constantly in manufacture in various stages. About 20,000,000 pens are made weekly in the town, and are sold at prices ranging from 1½d. to 12s. per gross of 12 dozen. The fact that each gross requires 144 pieces of steel to go through

12 different processes, renders this cheapness of sale one of the greatest marvels of manufacturing skill and industry. Electro-plating, first established about 1848 by Messrs Elkington and Mason, is one of the leading trades. Amongst other branches of manufacture are wire-drawing, bell founding, metal rolling, railway carriage building (a large and important industry), steel-toy making (including cutting implements and tools of all kinds), die-sinking, papier-maché making, and a variety of others, for which reference may be made to a volume entitled *Birmingham and the Midland Hardware District*, prepared on the visit of the British Association in 1865, and extending to more than 700 pages. It is impossible, indeed, in smaller compass to give an adequate idea of the variety and extent of Birmingham industry. To quote a modern writer:—

"We cannot move without finding traces of the great hive of metal makers—the veritable descendants of Tubal-cain. At home or abroad, sleeping or waking, walking or riding, in a carriage or upon a railway or steamboat, we cannot escape reminiscences of Birmingham. She haunts us from the cradle to the grave. She supplies us with the spoon that first brings our infant lips into acquaintance with 'pap,' and she provides the dismal 'furniture' which is affixed to our coffins. In her turn Birmingham lays the whole world under contribution for her materials. For her smiths, and metal workers, and jewellers, wherever nature has deposited stores of useful or precious metals, or has hidden glittering gems, there industrious miners are busily digging. Divers collect for her button makers millions of rare and costly shells. For her, adventurous hunters rifle the buffalo of his wide-spreading horns, and the elephant of his ivory tusks. There is scarcely a product of any country or any climate that she does not gladly receive, and in return stamps with a richer value."

These labours Birmingham performs with the aid of many thousands of willing hands, moved by busy and ingenious brains, and aided by her own great invention, the steam-engine; for by the genius of Watt and the intrepid courage of Boulton, Birmingham may claim the perfection of this discovery as her own. The memory of the great Soho factory is one of the most precious heritages of the town, and the name remains, for though the old factory has long since disappeared, the firm of Boulton and Watt still continue to make steam-engines in the immediate neighbourhood; and James Watt's own private workshop continues just as he left it, with no single article disturbed, carefully preserved in the garret of his house at Heathfield.

The mention of Watt and of Soho recalls the memories of distinguished inventors and others who have been connected with Birmingham. Johnson was a frequent visitor here to his friend Hector, the surgeon, on whose house in the Old Square a tablet (erected by the Shakespeare Club) bears witness to the residence of the great moralist. Then Baskerville, the printer, carried on his work here. The famous Lunar Society, fully described by Mr Smiles in his *Lives of the Engineers*, brought together a brilliant company—Watt, Boulton, Priestley, Josiah Wedgwood, Darwin, Parr, Withering, Edgeworth, Sir Joseph Banks, Herschel, Dr Solander, Fothergill, Roebuck, Galton, Keir, and many others. Murdoch, the inventor of gas, was a Soho man, and first used his invention to light the Soho factory at the peace of Amiens in 1802. Rickman, the reviver and historian of Gothic architecture, practised as an architect in Birmingham. Hutton, the antiquary and historian, carried on his bookselling business here. Many of the best engravers were Birmingham men, notably Willmore and Pye, the special translators of Turner's marvellous creations. In the ranks of landscape painters the name of David Cox will ever confer honour upon the town. Attwood, Joseph Parkes, and Bright speak for it in the region of politics and statesmanship. The series of inventors is continued to our own day by the names of Gillott, Elkington, Chance, Mason, and others.

In many respects Birmingham is a peculiar town, and in none more than the hold it has upon the affections of its people. A "Birmingham man" is usually a man of strong individuality, independence of character, facility of resource, and with an enduring love for "the old town." These traits of character are the result of a variety of circumstances. Birmingham is peculiar in opening a career even to the humblest who are gifted with ingenuity and industry. The great number of trades keeps work fairly constant, the skill required in them sustains wages of artizans at a high level, and the distribution of labour, and its dependence upon direct personal aptitude, afford chances of rising in the social scale which cannot be found in places where manufactures are mainly of one class and are conducted in factories demanding large capital. It is easy in Birmingham for a man to become a small master, and gradually to push his trade until he is able to establish a factory. Many of the largest employers have either been workmen themselves or are the sons of workmen; while of the smaller manufacturers almost all take a direct part in the handicraft work carried on in their places of business.

Wealth is more evenly distributed than in most other places. There are no colossal fortunes in Birmingham, and comparatively few large ones, and of these very few are made by speculative operations. To compensate for these distinctions there is an unusually large comfortable class — people of good though not excessive incomes derived from solid trade, or from savings made by hard personal and associated work. This class, touching the actually wealthy on one side, by easy and almost imperceptible stages touches the actual working-class on the other, and this latter class is constantly rising into the middle rank.

The Birmingham work-people, in their way, are courteous and helpful. This is probably owing to the free and open and common discussion of subjects of political and social interest engaged in without distinction of class. The same principle is adopted educationally—in the Midland Institute, for example—the Act of Parliament which established the Institute providing that the governing council shall always include artizan members. Another noticeable characteristic of the town is a development of means of self-instruction and of self-help. Birmingham was amongst the earliest places to establish a mechanics' institution, the place of which is now more efficiently supplied by the Midland Institute. Birmingham, again, was the birthplace of the freehold land and building societies, by which workmen are enabled, on easy terms, to acquire houses of their own; and in addition to these institutions, which are numerous and flourishing, it has a very large number of sick and friendly societies, savings-clubs, and other organizations of a provident kind,—more in proportion to population than, probably, any other of the large towns in England. Amongst the social characteristics it should be mentioned that there are few serious disputes between masters and workmen, and that strikes are infrequent, and when they do occur are found capable of easy adjustment by friendly negotiation. One point more is worthy of record—the constancy of the town to those who serve it. Many of the leading manufacturers and other citizens are members of the local governing bodies, and these and the parliamentary representatives are rarely changed by their constituents.

History.—Owing to its rapid expansion, and the consequent newness of most of the public and other buildings, Birmingham is often supposed to be a modern town. It is really one of the oldest in the country, and was in existence as a community in the Saxon period. Proof of this was given in 1309 by William de Bermingham, then lord of the manor, who showed in a law-suit that his ancestors had a market in the place, and levied tolls, before the Conquest. Some authors have endeavoured to identify the town with the supposed Roman station called Bremenium, but this claim has long since been abandoned as fabulous. The origin of the name is untraceable; the spelling of it is traceable in about 100 different forms. Dugdale, the historian of Warwickshire, adopts Brom-

wycham, and regards it as of Saxon derivation. Hutton, the historian of Birmingham, has the fanciful etymology of *Brom* (broom), *wych* (a descent), and *ham* (a home), making together, the home on the hill by the heath. As regards the history of the town, we must agree with Hutton that "the way is long, dark, and slippery." In *Domesday Book* it is rated at four miles of land with half a mile of woods, the whole valued at £203. Two hundred years later the family of De Bermingham, the owners of the place, come into sight,—one of them, William, being killed at the battle of Evesham, in 1265, fighting with Simon de Montfort and the barons against Henry the Third. The son of this William afterwards took part in the French war, and was made prisoner; his father's estates, forfeited by treason, were restored to him. Thenceforward we find the family engaged in various local and other offices, but seemingly abstaining from politics. They held the place until 1527, when Edward de Bermingham was deprived of his property by means of John Dudley, duke of Northumberland, who trumped up a pretended charge of riot and robbery against him, and procured Birmingham for himself. On the attainder of Dudley the manor passed to the Crown, and was granted to Thomas Marrow, of Berkswell, from whom by marriage and descent it went to Christopher Musgrave, and finally, as regards the only valuable part—the market tolls—by purchase to the town itself. In the Wars of the Roses it does not seem that Birmingham took any part; but energy revived in the civil war under Charles I., when the town sided actively with the Parliamentarians. In 1642, when Charles was marching from Shrewsbury to relieve Banbury, the Birmingham people seized part of his baggage, including much plate, money, and wine, which they sent to the Parliamentary garrison at Warwick. Before the battle of Edgehill Charles rested for two nights at Aston Hall, near the town, as the guest of Sir Thomas Holte. The Birmingham people resented this by helping the Parliamentarians to cannonade the hall and to levy a fine upon Sir Thomas Holte. They also set to work, and supplied the Parliamentary army with 15,000 sword blades, refusing to make a single blade for the Royalists. These manifestations of hostility were avenged in April 1643, by Prince Rupert, who, with 2000 men and several pieces of artillery, attacked the town, planting his cannon on an eminence near Sparkbrook, still known as Camphill. The townspeople resisted, but were beaten, many persons being killed or wounded. Amongst the former was Lord Denbigh, one of the Royalist officers. Having captured the place, Prince Rupert allowed his troops to plunder it, to burn about eighty houses, and to set their prisoners to ransom. He also levied a fine of £30,000, equal to at least £100,000 of the present value of money. This bitter lesson kept Birmingham quiet during the rest of the civil war, though the sympathies of the people with the Parliamentarians were unabated. In 1665 Birmingham suffered heavy losses by the plague, great numbers of dead being buried in the Pest Field, at Ladywood, then a lonely place far outside the town, but long since thickly covered with buildings. In 1688 the Revolution provoked a temporary outbreak of Protestant feeling. James II. had given timber from the royal forest of Needwood, near Burton, to build a Catholic chapel and convent in a place still called Mass-house Lane. This edifice the mob promptly destroyed when James gave place to William and Mary. Rather more than a century of quiet prosperity ensued, and then occurred the serious and most lamentable outbreak of popular fury known as the Church and King riots of 1791. For some years there had been much political activity in Birmingham, the dissenters, particularly the Unitarians, being desirous of relief from the political and religious disabilities under which they laboured. The leader in these movements was the famous Dr Priestley, who kept up an active controversy with the local clergy and others, and thus drew upon himself and his co-religionists the hatred of the more violent members of the Church and Tory party. The smouldering fire broke out on the occasion of the French Revolution. On the 14th of July a dinner of Birmingham Liberals was held at the Royal Hotel to celebrate the destruction of the Bastille. This was the signal of a popular outbreak. A Church and King mob, encouraged and organized by leaders of better station, but who were too cowardly to show themselves, began an attack upon the Unitarians. Dr Priestley was not present at the dinner, but his house at Fair Hill, Sparkbrook, was one of the first to be sacked and burnt—his library and laboratory, with all his manuscripts, the records of life-long scientific and philosophical inquiries, perishing in the flames. The house and library of Hutton, the historian and antiquary, were also destroyed. The Unitarian chapel was burnt, and several houses belonging to members of the sect were sacked and burnt. The riot continued until a strong body of troops was marched into the town, but before their arrival damage to the amount of more than £60,000 had been done. Some of the rioters perished in the burning buildings, in the cellars of which they drank themselves into stupefaction. Others were tried and imprisoned, and four of the prisoners were hanged. The persecuted Unitarians recovered a small part of their losses from the county; but Dr. Priestley himself, owing to the unworthy prejudice against him, was in a great measure forced to remove to the United States of America, where he spent the rest of his life. A late atonement was made by the town to his memory in 1873, by the erection of a statue in his honour in front of the Town-Hall, and the foundation of a Priestley scholarship at the Midland Institute.

As if ashamed of the excesses of 1791, Birmingham thenceforth became a thoroughly Liberal and, with one or two exceptions, a peaceful town. In the dismal period from 1817 to 1819, when the manufacturing districts were heavily distressed and were disturbed by riots, Birmingham remained quiet. Even when some of the inhabitants were tried and punished for demanding parliamentary representation, and for electing Sir Charles Wolseley as their delegate, there was no demonstration of violence—the wise counsels of the leaders inducing orderly submission to the law. The same prudent course was observed when in the Reform agitation of 1831–32 the Political Union was formed, under the leadership of Thomas Attwood, to promote the passing of the Reform Bill. Almost the whole town, and great part of the surrounding district, joined in this agitation; vast meetings were held on Newhall Hill; there was much talk of marching upon London 100,000 strong; but, owing to the firmness and statesmanship of Mr Attwood and his associates, there was no rioting or any sign of violence. Ultimately the Political Union succeeded in its object, and Birmingham helped to secure for the nation the enfranchisement of the middle classes and other political reforms. One exception to the tranquillity of the town has to be recorded—the occurrence of riots in 1839, during the Chartist agitation. Chartism took a strong hold in Birmingham, and, under the influence of Mr Feargus O'Connor and some of his associates, nightly meetings of a threatening character were held in the Bull Ring. The magistrates resolved to put these down, and having obtained the help of a detachment of the metropolitan police—the town then having no local police force—a meeting was dispersed, and a riot ensued, which resulted in injury to several persons, and required military force to suppress it. This happened on the 4th of July. On the 15th of the same month another meeting took place, and the mob, strongly armed and numbering many thousands, set fire to several houses in the Bull Ring, some of which were burned to the ground, and others were greatly damaged. The military again interfered, and order was restored, several of the ringleaders being afterwards tried and imprisoned for their share in the disturbance. There was another riot in 1867, caused by the ferocious attacks of a lecturer named Murphy upon the Roman Catholics, which led to the sacking of a street chiefly inhabited by Irishmen; but the incident was comparatively trivial, and further disorders were prevented by the prompt action of the authorities. (J. T. B.)

BIRON, Armand de Gontault, a baron and marshal of France, and a celebrated general, who signalized himself by his valour and conduct in several sieges and battles in the 16th century. He was made grand master of the artillery in 1569, and commanded at the siege of Rochelle, and in Guienne. He was one of the first who declared for Henry IV.; he brought a part of Normandy under his subjection, and dissuaded him from retiring to England or Rochelle. Biron was killed by a cannon-ball at the siege of Epernay, July 26, 1592. He was a man of considerable literary attainments, and used to carry a pocket-book, in which he noted everything that appeared remarkable. This gave rise to a proverb at court, when a person happened to say anything uncommon, "You have found that in Biron's pocket-book."

BIRON, Charles de Gontault, son of the above and born in 1562, created duke of Biron and admiral of France by Henry IV., was a man of great intrepidity, but fickle and treacherous. In 1601 he was sent as ambassador to the court of queen Elizabeth to announce his royal master's marriage with Mary of Medici; but being discovered in a treasonable correspondence with Spain, he was beheaded in the Bastille at Paris, July 31, 1602. The extent to which he had carried his treason was not great, and Henry by sparing his life would not have shown undue clemency.

BIRS NIMRUD. See Babylon, page 183.

BISACCIA, a city of Italy, in the Principato Ulteriore, 60 miles E. of Naples. It is a bishopric in conjunction with St Angelo, and contains 5342 inhabitants. Formerly it was the chief city in a principality belonging to the Pignatelli family, and it is believed to occupy the site of the ancient Romulea, a Samnite town of considerable size, which was captured by the Romans about 297 B.C.

BISCAY, or VIZCAYA, one of the three Basque provinces of Spain, with the title of Seignory. It is bounded on the N. by the bay to which it gives its name, E. by Guipuzcoa, S. by Alava, and W. by Santander. Its area is 845 square miles, and its population in 1867 was 183,098. The coast-line, which extends from Ondarroa to a short distance to the east of Castro, is bold and rugged, and in some places is deeply indented. The only river of any size is the Nervion or Ibaizabal, on which Bilbao is situated; the others, which are numerous, are merely large mountain streams. The surface of the country is for the most part very mountainous, but at the same time is diversified with numerous narrow valleys and small plains. Some of the mountains are almost entirely composed of naked calcareous rock, but most of them are covered to their summits with forests of oaks, chestnuts, or pine trees. Holly and arbutus are also common, and furze and heath abound in the poorer parts. The province produces wheat, maize, barley, rye, flax, grapes, peaches, apples, and other fruits. The farms are generally small, and are for the most part tilled by manual labour. The wild boar, lynx, fox, and other wild animals, are found in the forests; and deer, rabbits, partridges, woodcocks, and other kinds of game are plentiful. Sheep and goats are the principal domestic animals. In minerals Biscay is very rich. Iron of the finest quality is found in almost every part, and forms a main article of export. The best mines are those of Somorostro, near the coast. The amount obtained in 1866 was about 80,000 tons. Lead, zinc, alum, and sulphur, are also present in smaller quantities; and marble, lime, and sandstone are abundant. The manufacture of the iron ore is the chief branch of industry; but porcelain, linens, copper and brass wares, ropes, and leather, are also produced. The fisheries are actively prosecuted along the coast by a hardy race of fishers, who were the first of their craft in Europe to pursue the whale, formerly abundant in the Bay of Biscay. Cod, bream, tunny, and anchovy are the principal fish taken. Bilbao is the capital of the province, with a population of 17,649; the other towns, Portugalete, Miravalles, Durango, and Orozco, are all very small. The principal ports, besides Portugalete, are Plencia, Bermeo, and Ilea. After the fall of the Romans this Cantabrian province came successively into the hands of the Suevi, Franks, and Goths, and formed for some time an independent lordship. The legislative authority was exercised by the lord and a junta of popular representatives. The latter regularly assembled every two years, and on any emergency held an extraordinary meeting under an old tree at Guernica. Although incorporated with Spain, the Biscayans still maintain a republican form of administration, nominating their own governors and magistrates, regulating the amount of the taxes, and exercising various other privileges. They are a brave and active people, and their history is largely composed of exploits in defence of their liberties. For their linguistic and ethnographic affinities, see the article BASQUE PROVINCES. The name Biscay is not unfrequently employed as geographically equivalent to Basque, in that case including the three provinces of Biscay proper, Guipuzcoa, and Alava.

BISCAY, BAY OF, in French the Golfe de Gascogne, and the Roman *Sinus Aquitanicus*, an extensive gulf or bay of the Atlantic, enclosed by the northern coast of Spain and the western coast of France. It extends from the island of Ushant, on the coast of Finistère, to Cape Ortegal on the north of Galicia. In the Spanish portion of the bay the water is about 200 fathoms deep, while in the French portion it is only 20 fathoms. Navigation is impeded by strong westerly winds, and by Rennel's Current, which sets in from the west and sweeps along the southern and eastern shores sometimes at a rate of 27 miles a day. The Loire, Charente, Gironde, and Adour, besides numerous smaller streams from the Spanish mountains, fall into the bay.

BISCEGLIA, perhaps the ancient *Natiolum*, a fortified seaport of Italy, in the province of Terra di Bari, situated on a rocky promontory on the Adriatic, 21 miles W.N.W. of Bari. It is the seat of a bishopric, and has a cathedral, numerous churches and convents, and a theatre. Some ruins still exist of a hospital, founded by Bohemund for pilgrims to the Holy Land. Its harbour is only accessible to small vessels, and it has little trade. Being destitute of springs, it has numerous reservoirs for the collection of rain-water. Population, 21,371.

BISCHWEILER, a town of Alsace, 14 miles N. of Strasburg, on the railway from Hagenau. It has manufactures of woollen and linen stuffs, oil, soap, earthenware, &c., and some trade in hops, hemp, leather, and tobacco. Population in 1871, 9220, including that of Hanhoffen, which numbered 689.

BISCUIT. See BAKING, page 252.

BISHOP, the title of an ecclesiastical dignitary set over the presbyters and deacons at a very early period in the Christian church. The word is derived from the Saxon *biscop*, which is a corruption of the Greek word *episcopos*, which signifies an "overlooker" or "overseer," and the churches in which the order of bishops is recognized as distinct from and superior to the order of presbyters are styled "Episcopal churches." The early history of the Episcopal order is obscure, but it would appear that the first bishops were established in the chief cities of Christendom, and each bishop had a certain territorial district placed under his superintendence, whence the city was termed the see (*sedes*) of the bishop, and the district his parish (παροικία), and subsequently his diocese (διοίκησις). In course of time the districts assigned to the first bishops became too populous, whereupon the clergy of each diocese, as the case might be, appear to have assembled and to have subdivided the diocese, and to have selected a second bishop, and so bishops and dioceses were multiplied, according to the wants of the churches, until it was thought expedient to reserve the right of erecting new bishoprics to provincial councils, and this reservation was made a rule of the church by a decree of the Council of Sardica. Meanwhile the bishops of the new sees had grouped themselves round the bishops of the more ancient sees, who exercised over them a certain spiritual authority as primates, and presided in their councils; and as some of the great cities in which the sees of the first bishops had been established were distinguished by the title of "metropolis," or mother-city, and were in fact the chief cities of civil provinces of the Roman empire, the bishops of those sees came to be distinguished by the title of metropolitan bishops, and exercised a superior authority in the councils of the church in proportion to the greater importance of their respective sees. This superior dignity of the metropolitan bishops over the others was formally recognized at the Council of Nicæa as being in accordance with custom. Upon the establishment of Christianity as the religion of the Roman empire a coercive jurisdiction was engrafted on the spiritual superiority of the metropolitan, and the district over which the metropolitan exercised this jurisdiction was termed his province, the earliest ecclesiastical provinces being for the most part conterminous with the civil provinces of the empire. From the circumstance that there was no metropolitan city in Western Africa, the term metropolitan was never adopted in the Carthaginian Church, the senior bishop of that church being termed the primate, and having precedence and authority as such over the other bishops.

In the Church of Rome the Pope claims of right the

appointment of all the bishops; but the exercise of this right is modified by concordats with the sovereigns of the respective states. In France, since the concordat between Pope Leo X. and King Francis I., the sovereign has had the exclusive right of nominating the bishops, but the nomination is subject to the Pope's confirmation. In Austria (with the exception of four bishoprics), in Bavaria, in Spain, and in Portugal, the bishops are also nominated by the sovereign. In some countries the bishops are elected by the chapter of the cathedral church, as in Würtemberg, or by the bishops of the province, as in Ireland. In England, in the United States of America, and in Belgium, the Pope selects one out of a list of candidates submitted to him by the chapter. In all cases the bishop-nominate or the bishop-elect, as the case may be, has to obtain from the Holy See certain letters, entitled provisions, to authorize his consecration, and to recommend him to the protection of the sovereign and to the good offices of his metropolitan.

In the Church of Russia, after its separation from that of Constantinople, the right to elect a bishop was for some centuries vested in a synod of bishops, but by a regulation of the Emperor Peter the Great, the Holy Synod was restricted to recommend two persons to the sovereign for him to select one of them to be bishop. This regulation, however, is not always observed, and the sovereign, if he thinks fit, sets aside the list submitted to him by the Synod, and nominates of his own choice a person whom the Synod is obliged to elect. In Russia a diocese sometimes contains two capital cities, and the bishop has his title from both.

In the Church of the Levant, properly called the Greek Church, which is governed by the four patriarchs of Constantinople, Antioch, Jerusalem, and Alexandria, each patriarch has the right of confirming the election of the bishops within his patriarchate; but the firman or barat of the sultan is likewise necessary to give full authority to the bishops after their confirmation.

The bishops of the Church of England are twenty-eight in number, two of them being metropolitans, namely, Canterbury and York, who enjoy the more dignified title of archbishop, and have a special precedence assigned to them by law (see ARCHBISHOP). The twenty-six diocesan bishops, with the exception of the bishop of the Isle of Man, who is designated the bishop of Sodor and Man, are lords of parliament, and take precedence of the barons in the House of Lords; but the junior bishop for the time being is, by statute, disentitled from being summoned to parliament. From this disqualification the bishops of London, Durham, and Winchester are exempt. These three bishops have precedence over one another in the order in which their names are above mentioned, and they precede all the other bishops, the latter taking precedence of one another according to the date of their appointment. The junior bishop who has a seat in parliament acts as chaplain to the House of Lords.

In the Church of England the bishops exercise certain spiritual functions which are held not to be within the competence of the presbyters. They alone can administer the rite of confirmation to baptized persons, and they alone can ordain candidates for the sacred ministry. These functions the bishops exercise in virtue of their order, but they are also empowered by law to exercise a certain jurisdiction over all consecrated places and over all ordained persons. This jurisdiction they exercise for the most part through their consistorial courts, or through commissioners appointed under 3 and 4 Vict. c. 86, called the Church Discipline Act. The bishops also exercise a certain jurisdiction over marriages, inasmuch as they have by the canons of the Church of England a power of dispensing with the proclamation of banns before marriage. These dispensations are termed marriage licences, and their legal validity is recognized by the Marriage Act, 4 Geo. IV. c. 76. The bishops had formerly jurisdiction over all questions touching the validity of marriages and the status of married persons, but this jurisdiction has been transferred from the consistorial courts of the bishops to a court of the Crown by 20 and 21 Vict. c. 85. They have in a similar manner been relieved of their jurisdiction in testamentary matters, and in matters of defamation and of brawling in churches; and the only jurisdiction which they continue to exercise over the general laity is with regard to their use of the churches and churchyards. The churchwardens, who are representative officers of the parishes, are also executive officers of the bishops in all matters touching the decency and order of the churches and of th churchyards, and they are responsible to the bishops for the due discharge of their duties; but the abolition of church-rates has relieved the churchwardens of the most onerous part of their duties, which was connected with the stewardship of the church funds of their parishes.

The bishops are still authorized by law to dedicate and set apart buildings for the solemnization of divine service, and grounds for the performance of burials, according to the rites and ceremonies of the Church of England; and such buildings and grounds, after they have been duly consecrated according to law, cannot be diverted to any secular purpose except under the authority of an Act of parliament.

The bishops of England have also jurisdiction to examine clerks who may be presented to benefices within their respective dioceses, and they are bound in each case by the 95th canon of 1604 to inquire and inform themselves of the sufficiency of each clerk within twenty-eight days, after which time, if they have not rejected him as insufficiently qualified, they are bound to institute him, or to license him, as the case may be, to the benefice, and thereupon to send their mandate to the archdeacon to induct him into the temporalities of the benefice. Where the bishop himself is patron of a benefice within his own diocese he is empowered to collate a clerk to it,—in other words, to confer it on the clerk without the latter being presented to him. Where the clerk himself is patron of the living, the bishop may institute him on his own petition. See BENEFICE.

The qualifications of a bishop of the Church of England are, that he should be a learned presbyter of at least thirty years of age, born in lawful matrimony, and of good life and behaviour. The mode of his appointment is regulated by 24 Henry VIII. c. 20. Upon the avoidance of a bishopric the Crown is authorized to issue to the dean and chapter of the cathedral church of the see a licence for them to proceed to the election of a bishop, accompanied by a letter missive containing the name of the person whom they are to elect. The dean and chapter are thereupon required, within twelve days, to elect the person so named by the Crown to be the bishop of the vacant see, failing which election the Crown is impowered to name, by letters patent under the Great Seal addressed to the archbishop and metropolitan of the province, such person to be bishop as the Crown shall think able and convenient. Upon the election being reported to the Crown, a mandate issues from the Crown to the archbishop and metropolitan, requesting him and commanding him to confirm the election, and to invest and consecrate the bishop-elect. Thereupon the archbishop issues a commission to his vicar-general to examine formally the process of the election of the bishop, and to supply by his authority all defects in matters of form, and to administer to the bishop-elect the oaths of allegiance, of supremacy, and of canonical obedience.

After this formal confirmation of the bishop's election has taken place, the archbishop, with the assistance of at least two bishops, proceeds to consecrate the bishop-elect. The most important part of the religious ceremony on this occasion consists in the imposition of hands, in other words, in the archbishop and the bishops placing their hands simultaneously upon the head of the bishop-elect kneeling before them, and in the name of the Holy Trinity committing to him his office of bishop; after which the archbishop delivers to him the Holy Bible and addresses to him a short admonition to preach faithfully the Word of God. The bishop is required afterwards, by statute, to do homage to the Crown, upon which he is put into possession of the temporalities of his see. In the case of the avoidance of the archbishopric of either province, the Crown sends a mandate to the archbishop of the other province to confirm and consecrate the archbishop-elect, and the practice is, for the most part, for the archbishop of the other province to send a commission to four or more bishops of the province of the archbishop-elect to confirm his election and to invest and consecrate him.

Doubts having been raised whether a bishop of the Church of England, being a lord of parliament, could resign his seat in the Upper House of parliament, although several precedents to that effect are on record, a statute of the realm (19 and 20 Vict. c. 115), which is confined to the case of the bishops of London and Durham, was passed in 1856, declaring that on the resignation of their sees being accepted by their respective metropolitans, those bishops should cease to sit as lords of parliament, and their sees should be filled up in the manner provided by law in the case of the avoidance of a bishopric. By a subsequent statute (32 and 33 Vict. c. 111), provision has been made for the case of an archbishop or bishop being permanently incapacitated by age or mental infirmity. If the archbishop or bishop is capable of executing an act of resignation, a representation may be made to the Crown, which is impowered to declare the see to be vacant, but if the archbishop or bishop should be incapacitated from intimating his desire to resign his bishopric, the Crown may grant a licence to the dean and chapter of the cathedral church of the diocese to appoint a bishop-coadjutor. This Act was to be in force for two years; it has been continued for three years more by 35 and 36 Vict. c. 40.

A peculiar institution of the Church of England, established by 26 Henry VIII. c. 14, having been long allowed to remain dormant, has been recently revived, under which every archbishop and bishop, being disposed to have a suffragan to assist him, may name two honest and discreet spiritual persons for the Crown to give to one of them the title, name, style, and dignity of a bishop of any one of twenty-six sees enumerated in the statute, as the Crown may think convenient. The Crown, having made choice of one of such persons, is impowered to present him by letters patent under the great seal to the metropolitan, requiring him to consecrate him to the same name, title, style, and dignity of a bishop; and the person so consecrated is thereupon entitled to exercise, under a commission from the bishop who has nominated him, such authority and jurisdiction, within the diocese of such bishop, as shall be given to him by the commission, and no other.

The first colonial bishopric of the Church of England was that of Nova Scotia, founded in 1787, since which time various colonial bishoprics have been established, some of which were constituted by letters patent of the Crown only, whilst others have been confirmed by acts of the imperial or colonial legislatures. With regard to those bishoprics which have been constituted by letters patent of the Crown only, where the bishopric has been established in a Crown colony, the bishop is legally entitled to exercise the jurisdiction conferred upon him by the letters patent; but where the bishopric has been established in a colony possessing at the time an independent legislature, the bishop is not entitled to exercise such jurisdiction unless it has been confirmed to him by an imperial or colonial statute. The report of the judicial committee of the Privy Council in the case of the bishop of Natal (Moore's *Privy Council Reports*, N.S., iii. p. 115) is an exposition of the law on this subject. On the other hand, where bishoprics have been constituted by letters patent of the Crown, in pursuance of imperial statutes, as was the case of the East Indian bishoprics, or where bishoprics constituted by letters patent have subsequently been confirmed or recognised by colonial statutes, the bishop's jurisdiction is complete; otherwise his authority is only pastoral or spiritual. The practice adopted by the Crown, since the decision of the judicial committee in the case of the bishop of Natal has revealed the invalidity of the letters patent granted to many colonial bishops, has been to grant licences to the archbishop of Canterbury to consecrate bishops for the colonies without any definite diocese, and without any authority to exercise coercive jurisdiction. The Crown has also revoked the letters patent erecting Gibraltar into a bishop's see, and the last appointed bishop has been consecrated under a licence from the Crown, and is a titular bishop, having only consensual authority in that colony. (T. T.)

BISHOP, Sir Henry Rowley, musical composer, was born in London on the 18th November 1786. He received his artistic training from Francisco Bianchi, at whose instance, probably, he was employed to write his first work, the ballet of *Tamerlan et Bajazet*, produced at Covent Garden in 1806. This proved successful, and was followed within two years by several others, of which *Caractacus*, a pantomimic ballet, written for Drury Lane, may be named. In 1809 his first opera, *The Circassian's Bride*, was produced at Drury Lane; but by a singular misfortune the theatre was burned down after one performance, and the score of the work perished in the flames. His next work of importance, the opera of *The Maniac*, written for the Lyceum in 1810, established his reputation, and probably secured for him the appointment of composer for Covent Garden theatre. The numerous works—operas, burlettas, cantatas, incidental music to Shakespeare's plays, &c.—which he composed while in this position, are now in great part forgotten. The most successful were—*The Virgin of the Sun* (1812), *The Miller and his Men* (1823), *Guy Mannering* and *The Slave* (1816), *Maid Marian* and *Clari*, introducing the air of "Home, Sweet Home" (1822). His English adaptations, or rather mangled versions, of Mozart's *Don Giovanni* and *Figaro*, and Rossini's *Il Barbiere* and *Guillaume Tell*, were certainly no true service to art. It seems almost incredible that a man of Bishop's undoubted genius should have been so misguided as to suppress the incomparable *Figaro* overture of Mozart in favour of one of his own. In 1824 Bishop was induced by Elliston to transfer his services from Covent Garden to the rival house in Drury Lane, for which he wrote with unusual care the opera of *Aladdin*, intended to compete with Weber's *Oberon*, commissioned by the other house. As was to be expected the result was a failure, and with *Aladdin* Bishop's career as an operatic composer may be said to close. On the formation of the Philharmonic Society (1813) Bishop was appointed one of the directors, and he took his turn as conductor of its concerts during the period when that office was held by different musicians in rotation. In 1841 he was appointed to the "Reid" chair of music in the University of Edinburgh, but he resigned the office in 1843. He was knighted by the queen in 1842, being the first musician who ever received that honour. In 1848 he succeeded Dr. Crotch in the chair of music at Oxford. The music for the ode on the occasion of the installation of Lord Derby as chancellor of the university (1853) proved to be his last work. He died on the 30th April 1855 in impoverished circumstances, though few composers ever made more by their labours. Bishop's name will live in connection with his numerous glees, songs, and smaller compositions, rather than with his larger works, which are now seldom or never performed in their entirety. His Shake-

speare songs and glees are familiar favourites with all vocalists, and genius is discernible in not a few of them. His melodies are clear, flowing, appropriate, and often charming; and his harmony is always pure, simple, and sweet. He was a prominent example of both the strength and the weakness of the native English school, in which the name of Purcell alone stands unquestionably higher than his.

BISHOP-AUCKLAND, a market-town of England, in the county of Durham, 11 miles south-west of the city of Durham. It is beautifully situated on an eminence near the confluence of the Wear and the Gaunless; its streets are well paved and lighted, and there is a good supply of water. The parish church is 1 mile distant, at Auckland St Andrews, but there are several churches and chapels in the town. The town-house, which dates from 1863, is a handsome building, with a tower 100 feet in height; and the palace of the bishop of Durham, which stands at the north-east end of the town, is a spacious and splendid though irregular pile. The site of the palace was first chosen by Bishop Anthony Beck, in the time of Edward I. The present building covers about 5 acres, and is surrounded by a park of 800 acres. The principal industrial establishments are cotton-factories and engineering works; and in the neighbourhood of the town are several coal-mines. Population of local board district in 1871, 8736.

BISHOP-STORTFORD, a market-town of England, on the eastern border of Herts, 11 miles E.N.E. of Hertford, and 32 miles by railway from London. It is situated on both sides of the River Stort, a tributary of the Lea, and has thus direct water communication with the metropolis. The parish church of St Michael's, a fine building with a spire, dates from the reign of Henry VI., but was partly rebuilt in 1820. A town-house, a corn exchange, a union workhouse, a high school, a collegiate school, and a diocesan training school, are among the chief buildings; and there are also public baths, libraries, and banks. The industrial establishments comprise a brewery, malt-houses, coach-works, lime-kilns, and a foundry; and the trade consists chiefly in grain and malt. Stortford was in existence before the Norman conquest; and its castle, known as Waytemore Castle, was presented by William the Conqueror to Maurice, bishop of London, and his successors. The building was, however, demolished by King John, and only a few ruins remain. Sir H. Chauncey, the historian of Hertfordshire, and Hoole, the translator of Tasso, were both natives of Stortford. Population of the parish in 1871, 6250.

BISHOP-WEARMOUTH, a township of Durham in England, now incorporated in the parliamentary borough of Sunderland. See SUNDERLAND.

BISKARA, or BISKRA, a town of Algeria, in the province of Constantine, and the most important military post of the Sahara. It lies on the south side of the Aures Mountains, in a fertile district, watered by the Wadi Biskra. The streets of the town are broad, and its houses are for the most part built of brick, one story high, and with terraced roofs. Among the principal buildings are the fort of St Germain, the caravanserai, the hospital, and the barracks. A large caravan trade between the Sahara and the Tell passes through the town; iron, limestone, and saltpetre are obtained in the neighbourhood, and the surrounding country yields abundance of valuable dates. The chief articles of manufacture are burnous and carpets. An acclimatization garden has been established at Beni-Morra by the French, who first made themselves masters of Biskara in 1844. Population in 1872, 7367.

BISMUTH. This metal appears to have been unknown to the older metallurgical writers, it having been first noticed by Agricola, who speaks of it as a form of lead, and describes the method of separating it from its associated minerals by liquation. Mathesius in his *Bergpostilla*, written between 1553–1562, describes it as white like pyrites, and occasionally cubical like marcasite, easily overcome by the fire when melted, and running together with the tin, which thereby is rendered brittle and unsound,—the last remark referring to its occurrence with tin ores in Saxony. It was considered by the miners as a hopeful indication of silver, and even in certain cases is said to have been transformed gradually into that metal, as portions of the ore which had lain for some time exposed were found afterwards to be partly or wholly changed into silver. This remark is interesting, as the same belief seems to have come up again in our own time. The name *Wismuth* is a miner's term, whose origin is completely lost; but Mathesius assigns it a fanciful derivation from *Wisse* = *Wiese*, a meadow, because in the mine it is found covered with flowers or incrustations of various colours, resembling a meadow covered with brilliantly coloured flowers,—an obvious confusion with the minerals known as nickel and cobalt bloom, derived from the oxidation of arsenides of nickel and cobalt, with which native bismuth is commonly associated in Saxony. It is to this association with cobalt and arsenic that must be ascribed the statements that its principal use was to produce a blue colour, and that it gave off a very poisonous furnace smoke. The chief use of the metal at that time seems to have been by pewterers, who added it to their alloy in small proportions for the purpose of rendering their wares hard and sonorous when struck.

The principal minerals containing bismuth are:—1. Native bismuth, essentially *the pure metal*, having all the properties described below. This, the most important ore, occurs in connection with nickel and cobalt ores at Schneeberg, Saxony, at Wheal Sparnon in Cornwall, similarly associated, and with tin ores in the mines of the St Just district. It is also found in some quantity in Bolivia. 2. Tetradymite, or telluric bismuth, a compound in variable proportions with the isomorphous element tellurium. This contains from 60 to 80 per cent. of bismuth, 15 to 35 per cent. of tellurium, and from 3 to 5 per cent. of sulphur. It occurs usually in association with gold ores; the principal localities are Schemnitz and Retzbanya in Hungary, the gold mining district of Virginia and North Carolina, California, and other western states of America. It was also found at the Merionethshire gold mines as a rarity. 3. Bismuth silver, found at Schapbach in Baden, and near Copiapo in Chili. The mineral from the former locality contains 27 of bismuth to 15 of silver, with some lead and sulphur, and a little iron; and that from the latter 60 of silver to 10 of bismuth, the remainder being copper and arsenic. 4. Bismuthine, or bismuth glance, a sulphide of bismuth, of the composition Bi_2S_3, containing 81·6 per cent. bismuth and 18·4 per cent. sulphur, crystallizing in acicular rhombic prisms isomorphous with antimony glance. It occurs with tin ore at Botallack and other mines near St Just in Cornwall, and in the Saxon localities given above. 5. Bismuth ochre, an earthy oxide of bismuth, containing 90 per cent. bismuth and 10 per cent. oxygen, which is derived from the oxidation both of the native metal and of the sulphide. 6. Bismutite, a hydrated carbonate of bismuth, containing 90 per cent. bismuth oxide, 6·56 per cent. carbonic acid, and 3·44 per cent. water, another product of atmospheric action upon native bismuth. It is found principally in Saxony and South Carolina. Besides the above there is also a silicate described, but this is an exceedingly rare mineral, as is also Hypochlorite, a hydrated silicate mixed with phosphate of alumina. Practically the only ore is the native metal, and of late years, from the supply not keeping pace with the demand, the price has risen very considerably. The bismuth of com-

merce usually contains both gold and silver, often in considerable quantity, which circumstance has probably given rise to the story current about its transmutation into these metals.

Physical properties. Bismuth may be readily obtained in crystals by pouring it when melted into a heated iron ladle, and cooling it until a crust is formed on the surface, which must then be pierced by a red-hot iron rod, and the liquid metal poured off. The solidified portion adhering to the ladle is found to be covered with hopper-shaped crystals, which are usually beautifully irised, owing to the formation of a thin film of oxide on the surface, showing the colours of thin plates. This colouring is only obtained when the metal is quite free from arsenic. It may be purified by melting with about 10 per cent. of nitre, and keeping it constantly stirred at a temperature not much above its melting point, whereby the more oxidizable metals are removed, and form a slag at the surface. Another method of purifying it from arsenic is by fusing it with from 3 to 5 per cent. of zinc, covering the surface with charcoal to prevent oxidation of the zinc, which takes off the whole of the arsenic, and is subsequently removed by treatment with hydrochloric acid, the purified bismuth remaining insoluble. When prepared by any of these processes, Bismuth is a hard, brittle metal, and the fracture is highly crystalline and white, with a perceptible red tinge by reflected light. The crystalline form is rhombohedral, the angle of the primary rhombohedron being 87° 40′, or very close to a cube. The specific gravity is 9·83, but when subjected to great pressure the density is reduced to 9·6. The melting point is 264° C. (507° Fahr.) (Rudberg), or 268°·3 (515°) (Riemsdijk). Like water it may be cooled 6° or 7° C. below its freezing point; but when solidification sets in the temperature rises to 480° Fahr., and continues until the mass is completely solidified. Like ice it expands about $\frac{1}{32}$ of its volume in solidification, a property which is communicated to its alloys, rendering them valuable for taking casts of incised or relief surfaces for reproduction, as printing-blocks by electrotype or other processes. It may be distilled by heating to a higher temperature in hydrogen. Despretz volatilized it by subjecting it to the current from 600 Bunsen elements. The spectrum of the vapour in the voltaic arc shows numerous brilliant green lines, one strong and one fainter line on the red, and a faint line on the orange field (Masson). The coefficient of expansion by heat is ·001341, calorific conductibility 61, silver being 1000 (Calvert and Johnson), and specific heat 0·0305 (Kopp). The electric conductivity is 1·19 at 14° C., silver being 100 at 0° (Matthiessen). According to Matteuci the conductivity varies in the crystals according to the direction of the cleavages. It is the most strongly diamagnetic of all metals.

Chemical properties. The atomic weight is 208 (Schneider) or 210 (Dumas). Like phosphorus and arsenic it is both triatomic and pentatomic, the latter state being represented only by a very unstable acid; there are also several diatomic compounds, including $BiBr_2$, $BiCl_2$, and BiI_2. The triatomic compounds are the most numerous and stable. Unlike the elements chemically similar,—phosphorus, tellurium, arsenic, antimony, &c.,—it does not form a gaseous compound with hydrogen. Bismuth does not change in dry air, but in moist air it oxidizes superficially, and by long exposure may be converted into carbonate. When melted at a red heat it oxidizes, and the oxide (whose formula is $Bi_2O)_3$, by a higher temperature, melts to a glassy substance, in which property it resembles lead, the oxide, like litharge, exerting a very corrosive action upon earthern crucibles, or substances containing silica, at a red heat. At a red-white heat it slowly decomposes water with the production of oxide. The higher oxide Bi_2O_5 corresponds to arsenic acid; it is a very unstable compound, and of no practical value. An intermediate oxide is known which is generally regarded as a compound of the other two, Bi_2O_3, Bi_2O_5. Bismuth unites directly with chlorine, bromine, and iodine, and when fused with sulphur forms a sulphide of the form Bi_2S_3, corresponding to bismuth glance, and isomorphous with the corresponding sulphide of antimony. The same sulphide is produced when sulphuretted hydrogen is passed through a solution containing bismuth.

Salts. Bismuth is but slightly acted upon by hydrochloric or sulphuric acids in the cold; but the latter dissolves it more readily when heated. The best solvent is nitric acid, which attacks it readily, producing a nitrate which crystallizes from the concentrated solution in colourless transparent crystals belonging to the triatomic system, whose composition is $Bi \cdot 3NO_3 \cdot 5H_2O$. These crystals are soluble in nitric acid, but, like all neutral salts of the metal, are decomposed by water, with the formation of an insoluble basic nitrate and an acid liquor. These basic salts are very numerous and complex in constitution, the most important one being that represented by the formula $Bi.NO_3.H_2O$, which is known as pearl-white, *blanc de fard*. This, which is largely used as a medicine, is prepared by adding to a concentrated solution of bismuth dissolved in nitric acid from 40 to 50 times its weight of water, which precipitates a considerable proportion in the form of a white powder; the remainder, which is retained by the acid liquor, may be separated by neutralizing the excess of acid with ammonia, when a rather more acid salt than the first precipitate is obtained. Under the name of pearl-white the sub-nitrate is used as a cosmetic, but it has the disadvantage of being readily blackened by sulphuretted hydrogen.

Alloys. Bismuth unites readily with other metals, the alloys being remarkable for their ready fusibility, and by their property of expanding on solidification. An alloy with potassium is obtained by calcining 20 parts of bismuth with 16 parts of cream of tartar in a crucible, and heating the mixture to a very strong red heat. On cooling, a button of metal is found, of a silvery white colour and lamellar fracture, which fuses easily, and remains for a long time in a pasty condition before solidification; it is brittle, can be easily powdered, and is readily decomposed by water. The alloy with sodium is obtained in a similar manner, with a sodic tartrate. With silver, gold, and metals of the platinum group, bismuth forms brittle alloys. With mercury it forms a liquid amalgam; but when equal weights of the two metals are heated together, there is a separation on cooling of octahedral crystals, which may be a solid amalgam. The copper alloy is brittle, and of a pale red colour. The ternary alloys of lead, tin, and bismuth, are the most interesting of these compounds, from their low fusibility, which is much below that of any of the components taken separately. This property was known to Sir Isaac Newton; the alloy named after him, Newton's fusible metal, melts at 94°·5 C. (202° Fahr.); it contains 8 parts of bismuth, 5 of lead, and 3 of tin. Darcet's fusible metal, containing 2 of bismuth, 1 of lead, and 1 of tin, melts at 93° (199°·4 Fahr.) Another, with 5 of bismuth, 2 of tin, and 3 of lead, melts at 91°·6 (197° Fahr.) Rose's fusible metal, containing 420 parts of bismuth, 236 of lead, and 207 of tin, a composition corresponding to the formula Bi_2Sn_2Pb, fuses below 100° (212°), and remains pasty for a considerable range of temperature below that point. The expansion of this alloy by heat proceeds regularly from 0° to 35° C., but by further heating it contracts up to 55°, from which point up to 80° the rate of expansion is more rapid than at the lower temperatures. Above 80° the normal rate is resumed. The fusibility of these alloys is increased by an addition of cadmium. Thus Wood's fusible metal, containing 1 to 2 parts of cadmium, 2 of tin, 2 of lead, and 7 to 8 of bismuth, melts between 66° and 71° C. Another, described by Lipowitz, containing 8 parts of lead, 15 of bismuth, 4 of tin, and 3 of cadmium, is silvery white, and has a specific gravity of 9·4. It softens at about 55°, and is completely liquid at a little above 60°.

Fusible alloys containing bismuth are used to some extent as safety plugs for steam boilers, as an accessory to the safety-valve,—a hole in the boiler being plugged by a disc of the metal, which in the event of the temperature of the water rising through excessive pressure is melted, and the steam passes through the aperture in the same manner as through an opened safety-valve. It is found, however, that this method is not trustworthy, owing to the liquation of the more fusible components of the mass, when subjected to continued heating near but below the melting point, leaving a more refractory alloy behind. The alloy known as Britannia metal, consisting chiefly of tin, antimony, and copper, often contains a little bismuth.

Analysis and separation. In analysis bismuth is usually separated from solution as carbonate by precipitation with carbonate of ammonia, which is then converted into oxide by calcination at a gentle heat, in which form it is weighed and estimated. The oxide Bi_2O_3 contains 89·74 per cent. of bismuth. It is readily precipitated as sulphide by passing sulphuretted hydrogen through an acid solution, but the precipitate cannot be weighed, as it usually contains an excess of sulphur, and cannot be completely freed from water below 200°, so that it must be redissolved in nitric acid and precipitated as carbonate as above described. It may be precipitated in the metallic state by zinc, cadmium, copper, iron, or tin. A plate of copper introduced into a boiling solution of a bismuth salt, even when very weak, is readily covered with a coating of the reduced metal of a steel-gray colour.

Bismuth may be employed instead of lead for the assay of gold and silver by cupellation, as the melted oxide is absorbed by bone ash in exactly the same manner as litharge.

The separation of bismuth from solutions in which it is associated with silver, copper, mercury, cadmium, and lead, may be effected by cyanide of potassium; by digesting the solution with an excess of this reagent the cyanides of bismuth and lead remain in the insoluble portion, while those of the other metals are contained in the filtrate. On redissolving, the lead may be precipitated as sulphate, or by hydrochloric acid and alcohol, which renders the chloride of lead insoluble. The bismuth is finally precipitated from the filtrate by sulphuretted hydrogen. From copper it is readily separated by carbonate of ammonia, bismuth being precipitated, and copper remaining in solution. Another method is by heating in a current of chlorine, when chloride of bismuth is volatilized.

Metallurgy. The metallurgical processes for the extraction of bismuth are very simple, being mainly comprised in liquation out of contact with the air, and subsequent fusion of the liquated product of the first operation. At Schneeberg, in Saxony, the liquation is effected in cast-iron tubes placed transversely over a fire-grate which runs the whole length of the furnace. The tubes are inclined, the higher

end being open for charging, and the lower stopped, with the exception of a small hole for the passage of the separated metal, which is received in a cast-iron pot placed in front and heated with charcoal. The charge, about half a cwt. of ore, broken into pieces about half inch cube, occupies about half of the length and rather more than half the area of each tube. When all the tubes are charged the upper ends are stopped by sheet-iron doors, and heat is applied by means of a wood fire upon the grate. The liquid metal soon commences to flow, and is received in the pots in front. If the flow ceases through any obstruction the passage is cleared by an iron rod introduced through the aperture at the lower end. When the operation, which usually lasts about an hour, has terminated, the residues in the tubes are removed and thrown into a water trough placed behind the furnace on the charging side, and a fresh supply of ore is introduced. The bismuth collected in the pots is ladled out and cast into ingots of from 25 to 50 ℔ weight. In a furnace containing 11 tubes about 20 cwts. of ore may be heated daily with a consumption of 63 cubic feet of wood. In Plattner's modification the furnace is of the reverberatory form, the tubes being placed with their inclined axes in the direction of the flame, an arrangement which allows the use of a smaller fire-grate and a proportionate saving of fuel. At Joachimsthal, ores containing from 10 to 30 per cent. of bismuth are heated in a finely-ground state with scrap-iron, carbonate of soda, and a little lime and fluor-spar in earthen crucibles, which are heated until the mixture is completely fused, when the contents are poured into iron moulds of a sugar-loaf form. The bismuth collects in the point of the mould, and is covered with a cake of speiss, containing all the nickel and cobalt of the ore with about 2 per cent. of bismuth, which is reserved for further treatment; the slag filling the upper part of the mould is thrown away. If the bismuth is sufficiently rich in silver it is cupelled, and the oxide formed is subsequently reduced or revived by fushion with carbon. When argentiferous lead containing bismuth is subjected to cupellation the former metal is oxidized more rapidly than the latter, which accumulates to such an extent that it may often form a notable proportion of the litharge produced towards the end of the process, although not existing in sufficient amount to be appreciable by the ordinary processes of analysis in the original lead. This property has recently been utilized to recover a small quantity of bismuth existing in the silver ores smelted at Freiberg. The last portion of the litharge, and the hearth or test bottom from the silver refining furnace, are heated in quantities of 80 or 100 ℔ in earthenware pots with hydrochloric acid until complete solution of the bismuth oxide takes place, the proportion of acid and water being regulated to prevent the formation of insoluble salts. When the liquid is clear it is siphoned off to the precipitating tubs, where it is thrown down as an insoluble oxychloride by the addition of a large quantity of water. By redissolving and reprecipitating, a purer material is obtained, which is then dried and reduced by fusion in iron crucibles with carbonate of soda and charcoal. The production of bismuth annually in Saxony is about 22 tons, and in Austria about 17 cwt.

The principal properties and reactions of bismuth and its compounds were described in 1739 by Pott, who gave a summary of the information contained in the earlier writers. Our more exact knowledge of the subject is due to Neumann, Hellot, Geoffrey (1753), John Davy (1812), Lagerhjelm (1815), Stromeyer, and, more recently, Schneider and Nicklès. (H. B.)

BISON, a genus of Ruminant Mammals belonging to the family *Bovidæ*, and comprising two widely separated species—the European and American Bisons. They are distinguished from other bovine animals by the greater breadth and convexity of their foreheads, superior length of limb, and the longer spinal processes of the dorsal vertebræ, which, with the powerful muscles attached for the support of the massive head, form a protuberance or hump on the shoulders. The bisons have also fourteen pairs of ribs, while the common ox has only thirteen. The forehead and neck of both species are covered with long, shaggy hair of a dark brown colour; and in winter the whole of the neck, shoulders, and hump are similarly clothed, so as to form a "curly felted mane." This mane in the European species disappears in summer; but in the American Bison it is to a considerable extent persistent. The European Bison (*Bison bonassus*), or Aurochs of the Germans, is the largest of existing European quadrupeds, measuring about 10 feet long, exclusive of the tail, and standing nearly 6 feet high. Formerly it was abundant throughout Europe, as is proved by its fossil remains found on the Continent and in England, associated with those of the extinct mammoth and rhinoceros. These remains, while indicating larger proportions in the ancient aurochs than in those now living, do not, in Professor Owen's opinion, exhibit any satisfactory specific distinction. Cæsar mentions the aurochs as abounding, along with the now extinct *Bos primigenius*, in the forests of Germany and Belgium, where it appears to have been occasionally captured, and afterwards exhibited alive in the Roman amphitheatres. At that period, and long after, it seems to have been common throughout Central Europe, the Caucasus, and the Carpathian Mountains. It is now only found in one of the forests of Lithuania, where it is saved from immediate extinction by the protection of the emperor of Russia, but notwithstanding this it is gradually dying out. Many years ago the Lithuanian bisons numbered over 1000, but by the year 1872 they had diminished to 528, and all attempts to domesticate them have failed. The aurochs feeds on grass and the bark of young trees. The American Bison (*Bison americanus*) has its home on the eastern slopes of the Rocky Mountains, being seldom found to the west of these, and rarely to the east of the Appalachian range. Northwards it extends to lat. 63°, and southward as far as New Mexico. Those bisons or buffaloes, as the settlers call them, roam in enormous herds over the western prairies in quest of fresh pastures, being specially fond of the tender grass that springs up after a prairie fire. The two sexes live in separate herds during the greater part of the year, although one or two aged bulls, it is said, always accompany the females. During the rutting season when the sexes come together, the bulls engage in fierce fights among themselves, and at such seasons it is highly dangerous to approach them. At other times they are shy, and retreat before man; but when wounded they become furious, and then all the dexterity of the practised hunter is needed to make good his retreat. The Indians capture them in various ways; by hunting on horseback, and shooting them with bows and arrows, or with fire-arms; by snaring them within immense enclosures of snow, which the bisons are unable to overleap; or by attracting the herd towards a precipice, and then setting it in motion from behind, so that those in front are pushed irresistibly forward and over. The American Bison, though still found in considerable numbers, is rapidly diminishing before the advance of the white settler; and should man in the meantime not succeed in domesticating it, it will probably ere long share the fate which threatens its European congener. To the Indian the bison has hitherto been indispensable as an article of food, and for the many useful purposes to which its horns, skin, and hair are applied. Its hide forms an excellent fur wrapper; its great value in this respect was proved during the Crimean war.

BITHYNIA (Βιθυνία), a province in the N.W. of Asia Minor, adjoining the Propontis, the Thracian Bosphorus, and the Euxine. According to Strabo it was bounded on the east by the River Sangarius; but the more commonly received division extended it as far as the Parthenius, which separated it from Paphlagonia, thus comprising the district on the sea-coast between these two rivers, which was inhabited by the Mariandyni. Towards the west and south-west it was limited by the River Rhyndacus, which separated it from Mysia; and on the south it adjoined the portion of Phrygia called Phrygia Epictetus, and a part of Galatia. The territory thus defined is in great part occupied by mountains and forests, but has valleys and districts near the sea-coast of great fertility. The most important of the mountain ranges is that known as the Mysian Olympus—from its proximity to that province, though properly included within the limits of Bithynia—which rises to a height of about 6400 feet. It towers in a commanding manner above the city of Broussa, while it forms a conspicuous object as seen from Constantinople, at

See Plate II. Vol. xv.

a distance of 70 miles. Its summits are covered with snow for a great part of the year. Eastward of this the range now called Ala-Dagh extends for above 100 miles from the River Sangarius to the confines of Paphlagonia. It adjoins throughout its course the frontiers of Phrygia and Galatia, and rises to a height of from 6000 to 7000 feet. Both of these ranges belong to that border of mountains which bounds the great table-land of Asia Minor through a great part of its extent. The country between them and the sea-coast is for the most part occupied by subordinate mountain chains, which may be regarded as underfalls or offshoots of the more lofty mountain ranges of the interior. These constitute a very rugged and broken country, covered with extensive forests, and traversed by very few lines of route, so that it is still very imperfectly known. But the broad tract which projects towards the west as far as the shores of the Bosphorus, though hilly and covered with forests, so as to be termed by the Turks Aghatch Denizi, or "The Ocean of Trees," is not traversed by anything like a mountain chain.

The western coast of Bithynia, where it adjoins the Propontis or Sea of Marmora, is indented by two deep gulfs or inlets—the northernmost, now called the Gulf of Ismid, anciently known as the Gulf of Astacus, penetrating to a distance of between 40 and 50 miles into the interior, as far as the town of Ismid, the ancient Nicomedia, which is separated by an isthmus of only about 25 miles from the Black Sea. The next, known in ancient times as the Gulf of Cius, now called the Gulf of Moudania or Gemlik, extends to about 25 miles. At its extremity is situated the small town of Gemlik, on the site of the ancient Cius, at the mouth of a valley, through which it communicated with the inland lake of Isnik, on which was situated the flourishing city of Nicæa.

According to the general testimony of ancient authors (Herodotus, Xenophon, Strabo, &c.), the Bithynians were a tribe of Thracian origin who had migrated into Asia by crossing the Bosphorus. The existence of a tribe called Thyni in Thrace is well attested, and the two cognate tribes of the Thyni and Bithyni appear to have settled simultaneously in the adjoining parts of Asia, where they expelled or subdued the previously existing races of the Mysians, Caucones, and other petty tribes, the Mariandyni alone maintaining themselves in the north-eastern part of the country. Herodotus mentions the two tribes, the Thyni and Bithyni, as existing side by side; but ultimately the latter people must have become the more important, so as to give name to the whole country. They were first subdued by Crœsus, and incorporated with the Lydian monarchy, together with which they soon after fell under the dominion of Persia (546 B.C.) During the Persian empire they were included in the satrapy of Phrygia, which comprised all the countries up to the Hellespont and Bosphorus. But even before the conquest by Alexander some obscure native chiefs appear to have asserted their independence in the mountains of Bithynia, and successfully maintained it under two native princes named Bas and Zipœtes, the last of whom transmitted his power to his son Nicomedes I., who was the first to assume the title of king. He became the founder of the city of Nicomedia, which soon rose to great prosperity and opulence; and during his long reign (278–250 B.C.), as well as those of his successors, Prusias I., Prusias II., and Nicomedes II. (149–91 B.C.), the kingdom of Bithynia held a considerable place among the minor monarchies of Asia. But the last king, Nicomedes III., was unable to maintain himself against the increasing power of his neighbour Mithridates, king of Pontus; and although restored to his throne by the interposition of the Roman Senate, at his death, in 74 B.C., he bequeathed his kingdom by will to the Romans. Bithynia was now reduced into the form of a Roman province; but its limits were frequently varied, and it was commonly united for administrative purposes with the neighbouring province of Pontus, extending along the southern shore of the Black Sea as far as Trapezus or Trebizond. This was the state of things in the time of Trajan, when the younger Pliny was appointed governor of the combined provinces (103–105 A.D.), a circumstance to which we are indebted for much valuable information concerning the Roman provincial administration. Under the Byzantine empire Bithynia was again divided into two provinces, separated by the River Sangarius, to the westernmost of which the name of Bithynia was restricted.

The most important cities of Bithynia in ancient times were Nicomedia and Nicæa, which disputed with one another the rank of its capital. Both of these were founded after the time of Alexander the Great; but at a much earlier period the Greeks had established on the coast the colonies of Cius (afterwards named Prusias), on the site of the modern Gemlik; Chalcedon, at the entrance of the Bosphorus, nearly opposite Constantinople; and Heraclea, surnamed Pontica, on the coast of the Euxine, about 120 miles east of the Bosphorus. All these rose to be flourishing and important places of trade. Prusa, at the foot of Mount Olympus, which was founded by Prusias, was also a considerable town under the Roman empire, but did not attain in ancient times to anything like the importance enjoyed by the modern city of Broussa, which became the capital of the Ottoman Turks before the conquest of Constantinople, and is still (after Smyrna) the second city of Asia Minor. The only other places of importance at the present day are Ismid (Nicomedia) and Scutari, which, from its position on the Bosphorus, may be considered as a mere suburb of Constantinople.

The natural resources of Bithynia are still very imperfectly developed. Its mountains are covered with vast forests, which would furnish an almost inexhaustible supply of timber, if rendered accessible by roads. Coal also is known to exist in the neighbourhood of Erekli (Heraclea), but is not worked to any extent. The valleys which open towards the Black Sea abound in fruit trees of all kinds, while the valley of the Sangarius and the plains near Broussa and Isnik (Nicæa) are fertile and well cultivated. Extensive plantations of mulberry trees supply the silk for which Broussa has long been celebrated, and which is manufactured there on a large scale.

The principal rivers of Bithynia are the Sangarius, still called the Sakaria, which traverses the province from S. to N.; the Rhyndacus, which forms the boundary that separated it from Mysia; the Billæus (Filyas), which rises in the chain of the Ala-Dagh, about 150 miles from the sea, and after flowing by the town of Boli (the ancient Claudiopolis) falls into the Euxine, close to the ruins of the ancient Tium, about 40 miles N.E. of Heraclea. It has a course of more than 100 miles. The Parthenius (now called the Bartan), which forms the boundary of the province towards the E., is a much less considerable stream. (E. H. B.)

BITONTO, a city and bishop's see, in the province of Bari, in South Italy, on the great road from Foggia to Bari, about 12 miles from the latter town. Its cathedral, dedicated to St Valentine, is a fine building in the Italo-Gothic style; and it possesses a theological seminary, a large orphan asylum, and a hospital. The inhabitants maintain an active trade, and have extensive manufactures of olive oil. Their principal export is an excellent wine known as Zagarelle. Bitonto, or Butuntum, seems from its coins to have been a place of some importance at an early period, but it makes no appearance in ancient history. In the Middle Ages its *Accademia degl' Infiammati* obtained

considerable fame. In 1735 it was the scene of a severe battle, in which the Austrians were defeated by the Spaniards under Mortemar, in whose honour Philip V. caused a pyramid to be erected on the spot. Population in 1871, 24,978.

BITSCH (French, BITCHE), formerly KALTENHAUSEN, a town and fortress in German Lorraine, on the River Horn, at the foot of the northern slope of the Vosges, between Hagenau and Saargemund. It was originally a countship in the possession of the counts of Alsace and Flanders, but was bestowed by Frederick III. on the dukes of Lorraine, and at length passed with that duchy to France in 1738. After that date it rapidly increased, and its citadel, which had been constructed by Vauban on the site of the ducal palace, was restored and strengthened. The attack upon it by the Prussians in 1793 was repulsed, and although the Bavarians occupied the town in 1815 and 1818, they did not get possession of the fort. In the war of 1870 it was blockaded by the Germans in vain, and only surrendered in 1871, after the campaign was over. A large part of the fortification is excavated in the red sandstone rock, and rendered bomb-proof; while a supply of water is secured to the garrison by the possession of a deep well in the interior. The inhabitants of the town, who in 1871 numbered 3047, manufacture watch-glasses and matches, and carry on a trade in grain, cattle, wood, and peats.

BITTERN, a genus of Wading Birds, belonging to the family *Ardeidæ*, comprising several species closely allied to the Herons, from which they differ chiefly in their shorter neck, the back of which is covered with down, and the front with long feathers, which can be raised at pleasure. They are solitary birds, frequenting countries possessing extensive swamps and marshy grounds, remaining at rest by day, concealed among the reeds and rushes of their haunts, and seeking their food, which consists of fish, reptiles, insects, and small quadrupeds, in the twilight. The Common Bittern (*Botaurus stellaris*) is nearly as large as the heron, and is widely distributed over the eastern hemisphere. Formerly it was common in Britain, but the extensive drainage of late years has greatly diminished its numbers, and it is now a permanent resident only in the fen districts of England. The bittern in the days of falconry was strictly preserved, and afforded excellent sport. It sits crouching on the ground during the day, with its bill pointing in the air, a position from which it is not easily roused, and even when it takes wing, its flight is neither swift nor long sustained. When wounded it requires to be approached with caution, as it will then attack either man or dog with its long sharp bill and its acute claws. It builds a rude nest among the reeds and flags, out of the materials which surround it, and the female lays four or five eggs of a uniform dusky brown. During the breeding season it utters a booming noise, from which it probably derives its generic name, *Botaurus*, and which has made it in many places an object of superstitious dread. Its plumage for the most part is of a pale buff colour, rayed and speckled with black and reddish brown. The American Bittern (*Botaurus lentiginosus*) is somewhat smaller than the European species, and is found throughout the central and southern portions of North America, where it forms an article of food. It also occurs in Britain as an occasional straggler.

BITTERS, an aromatized alcoholic beverage, so named originally in the United States, where it was first used on account of its flavour and tonic influence. The drink by itself, or as an addition to unflavoured spirits, is used with considerable frequency in Europe, and especially in France it has come to be favourably regarded as a substitute for the insidious and deleterious absinthe. In the year 1867 the daily consumption of bitters in Paris alone had reached 4000 litres. The preparation of bitters in Europe was at first a *spécialité* of the Dutch, and Dutch bitters are the staple used in Great Britain. A considerable variety of recipes are in use for the preparation of Dutch bitters, but generally gentian root is the leading bitter ingredient in the beverages. The following is given as the composition of brandy bitters:—Gentian root, 4 oz.; orange peel, 5 oz.; cassia bark, 2 oz.; cardamoms, 1 oz.; and proof spirits, 1 gallon, coloured with ½ oz. of cochineal. Bitters prepared in the great French cities—Bordeaux, Rouen, Havre, Paris, &c.—contain extracts of gentian root, bitter orange peel, and orange flowers, with a proportion of sugar, and possess an alcoholic strength of about 40°.

BITUMEN. See ASPHALT, vol. ii. p. 715.

BIZERTA, or BENZERT, a seaport of North Africa, in Tunis, 38 miles from the capital, on a gulf or salt lake of the same name, which communicates with a shallow fresh water lake in the interior, formerly called Sisara, and now the lake of Gebel Ishkel. It occupies the site of the ancient Tyrian colony Hippo Zaritus, the harbour of which, by means of a spacious pier, protecting it from the north-east wind, was rendered one of the safest and finest on this coast. This important work, however, having been neglected by the Turks, the port has been to a great extent choked up. It is still visited by small vessels, and a certain amount of trade is carried on. The exports in 1869 were valued at £19,759. The town is about a mile in circuit; it is defended by several forts. The principal employment of the inhabitants is fishing. The adjoining lake abounds in fish, particularly mullets, the roes of which, dried and formed into the substance called botargo, form a considerable article of Mediterranean commerce. N. lat. 37° 17′, E. long. 9° 50′. Population, 8000.

BLACK, DR JOSEPH, a celebrated chemist, was born, in 1728, at Bordeaux, where his father—a native of Belfast, but of Scottish descent—was engaged in the wine trade. He was educated from his twelfth to his eighteenth year at a grammar school in Belfast, whence he removed, in 1746, to the university of Glasgow. There he chose medicine as his profession, and devoted himself earnestly to physical science, being encouraged and guided by Dr Cullen, who then lectured on chemistry in Glasgow, and whose liberal and original views were in unison with Black's own aspirations. From assisting in Cullen's chemical experiments he acquired the delicate manipulative skill essential to success in original scientific research.

In 1751 he went to complete his medical studies at Edinburgh, and after taking his medical degree there in 1754 revealed himself as a great scientific discoverer. At that time the causticity of the alkalies was attributed to their absorbing an imaginary fire-essence known as phlogiston, an hypothesis which Black overthrew by showing that their causticity depended on their combining with a ponderable gas, carbonic acid, which he named *fixed air*, meaning that it was found not only as a separate fluid, but as *fixed* in solid bodies. This discovery, made by Black in his twenty-fourth year, was first sketched in a treatise, *De Acido e Cibis orto, et de Magnesia*, and afterwards embodied in his work, *Experiments on Magnesia, Quicklime, and other Alkaline Substances*, which Lord Brougham has declared to be "incontestably the most beautiful example of strict inductive investigation since the *Optics* of Sir Isaac Newton."

These works revolutionized chemistry. Previous investigators imagined that atmospheric air was the sole permanently aeriform element, a belief to which even Hales, who had shown that solids contain elastic fluids, had adhered. But when Black proved that a gas not identical with atmospheric air was found in alkalies, it was made plain

that various dissimilar gases might exist, and pneumatic chemistry was founded.

Although the full value of this discovery was not immediately visible, it added so greatly to Black's reputation that in 1756 he was chosen to succeed Dr Cullen as lecturer on chemistry in Glasgow University. He was also appointed to the chair of anatomy, but, not finding its duties congenial, exchanged it for the professorship of medicine. For some time he was so assiduous in preparing his lectures as to neglect fresh investigations, and even left the examination of carbonic acid, or *fixed air*, to be afterwards completed by Cavendish. He was highly esteemed as a professor by his students and colleagues, and became, through his attention and urbanity, a very popular physician in Glasgow. From 1759 to 1763 he prosecuted inquiries resulting in his theory of *latent heat*, which may be thus summarized—A solid liquefies or a fluid vaporizes through heat uniting with the solid or fluid body, and a fluid solidifies or a gas liquefies through the loss of heat; but in no case is this increase or diminution of heat detected by the senses or the thermometer. Black therefore named that heat *latent* which alters the condition, not the temperature, of a body. He likewise proved that bodies of equal masses require different increments of heat to raise them to the same sensible temperature—a doctrine now known as the law of *specific heat*.

His theory of latent heat he corroborated by numerous experiments, but he never published a detailed account of it, an omission which enabled others to lay claim to his great discovery. Thus M. Deluc, in 1788, declared himself its author. In 1766 Black was elected to succeed Cullen in the chair of chemistry at Edinburgh University. In this office he bestowed great care on his lectures, striving to give a lucid exposition of ascertained facts rather than to effect new discoveries; and such an interest did he communicate to his subject, that chemistry was for a time, it is said, regarded as a fashionable accomplishment in the Scottish capital.

He was intimate with the great men who adorned Edinburgh society during the second half of the eighteenth century, counting among his friends Watt, Hume, Robertson, Hutton, Adam Smith, and, at a later period, Robison, Playfair, and Dugald Stewart. His constitution had always been feeble, and he was ultimately reduced to the condition of a valetudinarian, which may account for the indifference he manifested during his latter years to original research. He retired from his professorship in 1796, and on the 26th November 1799 passed away so quietly that a cup of water, which he had held in his hand, remained unspilled after he had breathed his last. At the instance of Lavoisier he had been elected a member of the Paris Academy of Sciences.

Black was singularly modest, gentle, and sincere; his philosophic tranquillity was seldom ruffled; and his sagacious diffidence was equally conspicuous in his scientific inquiries and in his social relations. He has been called the founder of modern chemistry. When he began his career that branch of knowledge had only recently been raised to the rank of a true science through the efforts of Hermann Boerhaave, and was in many quarters even regarded with suspicion as being akin to alchemy on the one hand, and to humble trades on the other. But after Black's discoveries its scope and capabilities were immensely extended, and no one could then question its claim to rank with the most important sciences. The only works of his which appeared in print during his lifetime were *Experiments on Magnesia*, &c., *Observations on the more ready Freezing of Water that has been boiled*, and *Analysis of the Waters of some Boiling Springs in Iceland*. His lectures on chemistry were issued after his death. (*Cf.* Prof. Robison's *Life of Black*.)

BLACK FOREST (German, SCHWARZWALD), an extensive upland district on the right bank of the upper Rhine, stretching from that river to the Neckar and upper Danube. See BADEN and WÜRTEMBERG.

BLACK SEA, or EUXINE, the *Pontus Euxinus* of the ancients, is a large inland sea, bounded on the W. by the Turkish provinces of Rumilia, Bulgaria, and Moldavia; on the N. by South Russia, including Bessarabia, Kherson, and Taurida; on the E. by the Russian provinces of Circassia and Transcaucasia; and on the S. by the Turkish provinces of Asia Minor. It is entered from the Mediterranean through the channel of the Dardanelles or *Hellespontus*, the Sea of Marmora or *Propontis*, and the channel of Constantinople or *Thracian Bosphorus*; and it is connected with the Sea of Azoff, or *Palus Mœotis*, by the strait between the Crimea and the isle of Taman, anciently the *Cimmerian Bosphorus*, and known by the various modern names of the Strait of Kertch, of Yenikale, and of Taman.

The first navigators of Greece who ventured into this sea having been repulsed or massacred by some of the fierce tribes inhabiting its coasts, their countrymen gave it the name of *Pontus Axenos*, or "sea unfriendly to strangers." But when the repeated visits of the Greeks had rendered these tribes more familiar with strangers, and commercial intercourse had softened down the original ferocity of their character, Grecian colonies were established at different points on the shores of this sea, and the epithet *Axenus* was changed into *Euxinus*, which has the opposite import, and means "friendly to strangers." The modern name seems to have been given to it by the Turks, who being accustomed to the navigation of the Ægean, the islands of which furnish numerous harbours of refuge, were appalled by the dangers of a far wider expanse of water without any shelter, subject to sudden and violent storms, and often covered with dense fogs.

The basin of the Black Sea is of an irregular ovate form, its long diameter lying nearly E. and W. Its greatest length, from the head of the Bay of Burghaz in Rumilia on the west to the boundary between Transcaucasia and Asiatic Turkey near Batum on the east, is about 720 miles. Its greatest breadth is in its western portion, between the estuary of the Dnieper on the north and the mouth of the Sakaria on the south, where it is 380 miles; its middle portion is narrowed, by the projection of the Crimean peninsula on the north and of the coast line of Anatolia between Cape Kerempe and Sinope on the south, to 160 miles; but further east it widens out again between the Strait of Kertch on the north and the mouth of the Kizil Irmak (the ancient *Halys*) on the south, to 260 miles. Its total area, including the Sea of Azoff, is about 172,500 square miles. The western coast line of the Black Sea, for some distance northwards from the Bosphorus, is high and rocky, having ranges of hills at its back; and the water rapidly deepens to from 30 to 40 fathoms. Between their northern extremity and the range of the Balkans (the ancient *Hæmus*), which extends east and west, terminating in Cape Emineh, there is a large bay, named after the town of Burghaz at the head of it, which affords a safe anchorage for large ships, the only one on this coast. Between Cape Emineh and Varna the coast line is again low and the shore shallow; and the same condition extends, with but little interruption, along the low-lying region called the Dobrudscha, which extends to the mouth of the Danube. This great river discharges itself by seven mouths, among swampy islands and shifting banks; and the quantity of *detritus* brought down by it is so large as not only to form a very extensive bar, but also to require the con-

tinual use of artificial means for its removal from the bed of the navigable channels. The same low coast-line continues along the southern boundary of the Russian steppes, to the shallow inlet which forms the estuary of the Dniester, and of which the mouth is nearly closed by a bar; beyond which, towards Odessa, the coast-line is more lofty, and the waters deepen more rapidly, so that it has been possible to construct a harbour in which ships of considerable tonnage can lie securely. Between Odessa and the mouth of the Dniester the shore again becomes low, and the water shallow; and the outlet of that river, which also receives the River Bog or Bug, is a long shallow bay bordered by shifting sand banks, which is called the Gulf of Leman or the Bay of Kherson. Only ships of light draught of water can navigate these rivers, of which the Bug is the deeper; and vessels of war, which are built and repaired at the arsenals of Kherson and Nicolaieff, are artificially floated up and down. The Crimean peninsula is separated from the mainland on the western side by the Gulf of Perekop, the northern boundary of which is formed by a narrow belt of sand that runs nearly straight for a distance of 80 miles, and was celebrated by ancient geographers as the δρόμος Ἀχιλλέως. The inner portion of this gulf is so shallow that only vessels of very light draught can make their way to Perekop, which is situated on the narrow isthmus that divides it from the Sea of Azoff. Along the western coast of the Crimea, however, the coast-line gradually rises, and the shore deepens more rapidly; and at Eupatoria there is a good harbour for ships of moderate size. South of Eupatoria, the coast is formed by cliffs, sometimes of considerable height; and the water is deep almost to their base. The harbour of Sebastopol somewhat resembles that of Valetta in being a deep inlet, subdividing into several branches, in any one of which the largest vessels may find good anchorage, and lie within a cable's length of the shore. Between Sebastopol and Cape Chersonese are six other bays running inland parallel to each other; and on rounding this we arrive at the harbour of Balaclava, which is a remarkable inlet, having a very narrow entrance, and almost entirely surrounded by lofty heights. Eastward from Balaclava there commences an almost continuous chain of lofty cliffs, with mountains behind them, whose height ranges from 4000 to 5800 feet; the commencement of this chain is formed by Cape Aia or Tarchanskoi, probably the *Parthenium* of Strabo, the most remarkable headland in the Crimea. Along the whole south-east coast of the Crimean peninsula the water is deep; but there is no good harbour between Balaclava and the Bay of Kaffa, which furnishes an excellent and sheltered anchorage for large vessels, and was formerly much frequented when Kaffa or *Theodosia* (an ancient Greek colony) was a port of considerable importance. The peninsula of Kertch and the island of Taman, which separate the Sea of Azoff from the Black Sea, are for the most part low and sandy, the most elevated land in each being near the border of the Strait of Yenikale. On the western side of this strait the town of Kertch is situated, upon what was formerly known as the Hill of Mithridates.

The Sea of Azoff may be considered as the wide shallow estuary of the River Don, which discharges its waters into the north-eastern prolongation of the sea, sometimes distinguished as the Gulf of Taganrog; its area is estimated at about 14,000 square miles; and its depth, which is nowhere more than 7½ fathoms, diminishes near the shores to 4½ fathoms, and is less than 2 fathoms opposite the town of Taganrog. These depths show a tendency to yet further diminution through the deposit of river *detritus*,—vessels which could formerly pass up the gulf as far as Taganrog being no longer able to do so, whilst during certain winds the bottom becomes dry enough to be crossed between Taganrog and Azoff. The western portion of this basin is separated from the rest by a long narrow strip of low sandy land, enclosing what was named by the Greeks the Putrid Sea,—into which, when the wind is easterly, the water of the Sea of Azoff passes through a narrow opening at the northern extremity of the bar, but which at other times consists of a series of swamps and quagmires, equally impassable to men and animals, and giving forth noxious exhalations that render the adjacent country nearly uninhabitable. The water of the Sea of Azoff is always less salt than that of the Black Sea; and when the Don is at its fullest, the large quantity of fresh water which is mingled with the water of the sea renders the latter nearly drinkable, and tends to empty the basin of its salt. When, on the other hand, the river brings down but little water, and the wind is from the south, there is a considerable reflux of the more saline water outside; and thus the average salinity of the water of the Sea of Azoff is maintained,—just as is seen to be the case on a larger scale with the Baltic. See BALTIC, p. 297.

The whole of the portion of South Russia that lies between the Dnieper and the Don is an almost unbroken *steppe*, but very little elevated above the sea-level; and there are abundant indications of its having been at no remote period covered by salt water. For not only are there numerous salt lakes and marshes at a long distance inland from the present coast-line, but extensive beds of sea-shells, which have become mineralized into strata of solid limestone, sometimes 30 or 40 feet in thickness. The like features prevail over the plain which lies between the Don and the Kuban, and which forms the eastern boundary of the Sea of Azoff; this plain, inhabited by nomade Kalmucks and Cossacks, extends eastward to the desert of Astrakhan; and as salt marshes and beds of sea-shells are found there also, it is evident not only that both the Black Sea and the Caspian extended farther north than they do at present, but that they were then in continuity with each other over the plain of South Russia, though separated towards the south by the Caucasian Highlands. It is interesting to note that Pliny expressly stated that the Tauric Chersonese was not only surrounded by the sea, but that the sea covered all that northern portion of it which is now an alluvial level.

The island or peninsula of Taman, which forms the eastern border of the Strait of Yenikale, is for the most part an expanse of salt-marshes and lagoons, into which the River Kuban discharges itself,—one portion of its water passing into the Sea of Azoff and the rest into the Black Sea. At Anapa, a little to the east, the Caucasian range comes down to the sea; and thence around the shore of Circassia, the coast-line is high with a mountainous back-ground, and the water rapidly deepens. As the great mountain range trends inland, however, the coast becomes lower; and the region now termed Mingrelia, the ancient *Colchis*, is a fertile plain, through which run the River Rion (the ancient *Phasis*) having the important port of Poti at its mouth, and the Khopi, at the mouth of which is Redout Kale. Through these channels the merchants of Tiflis export the produce of the interior, and import European goods. Passing the boundary between Russia and Turkey, the coast-line begins to trend westwards, to the outlet of the large river Chouruk (the ancient *Batys*), where the fortified town of Batoum is situate at the base of the northern mountain range of Asia Minor. This range extends, with occasional interruptions, along the whole southern coast of the Black Sea, sending down spurs that form headlands and promontories, sometimes of considerable height. Owing to the steepness of the shores, there are few good anchorages here, except in the Bay of Samsoun, which receives the River Yeshil, and the Bay of Sinope, which receives the Kizil-Irmak,—at the mouths of which rivers there are plains formed by their alluvial deposit. From Cape Injeh westward to the Bosphorus, the coast-line of Anatolia is continuously elevated, with high mountains in the back-ground, occasionally projecting seawards as lofty promontories, of which Cape Kerempe is the most noteworthy; numerous rivulets come down from the mountains, and discharge themselves into

little coves; but excepting the Sakaria (the ancient *Sangarius*), there is no considerable river, and the water deepens very rapidly to 20 fathoms or more.

Although it is known that the depth of the central part of the basin of the Euxine reaches 1070 fathoms, the extent of this deep depression is not known. The increase of depth off the low-lying western and north-western shores is very gradual and regular, the lines of 20, 30, and 60 fathoms maintaining a general parallelism to the coast,—so that within this range the distance of a ship from land can be approximately ascertained by sounding. But outside the 60 fathom line the bottom deepens more rapidly and less regularly, depths of from 600 to 700 fathoms being met with in some parts within a few miles of it. The depth of the eastern portion of the basin has not been ascertained, but it is probably considerable.

The basin of the Euxine communicates with that of the Sea of Marmora by the Bosphorus, a strait about 20 miles long, from ¾ to 2¼ miles wide, and a depth of from 30 to 40 fathoms, resembling a broad river with high banks, which maintain a general parallelism, although the strait has seven distinct reaches. The region on either side presents distinct evidence of recent volcanic action.

The Sea of Marmora lies in the course of the channel that connects the Black Sea with the Ægean. Its bottom is depressed to a depth far greater than that of the channel of which it is an expansion. Its length from strait to strait is 110 geographical miles, and its greatest breadth is 43 miles. Round the shores, the depth generally ranges from 10 to 30 fathoms; but it rapidly increases in most parts; and depths of 100, 133, 266, and even 355 fathoms have been met with, chiefly near the line connecting the two straits.

The channel which connects the Sea of Marmora with the Ægean is properly termed the Hellespont,—the name Dardanelles, by which it is commonly known, being really that of the fortifications erected on the two sides of the strait by which its passage is guarded. The Sea of Marmora narrows to a breadth of ten miles towards the north-eastern entrance of the channel; at Gallipoli, the distance between the two shores suddenly contracts to about two miles; and between this and the Ægean end of the strait, that distance is further diminished at certain points to even less than a mile. The depth of the channel is considerable, being for the most part between 30 and 50 fathoms.

Climate.—The climate of the Black Sea is very peculiar,—the *range* of temperature between the summer and winter extremes being remarkably great. The *summer* isotherm of 70° runs a little way inland, nearly parallel to its north-western coast-line, whilst the summer isotherm of 80° passes along its southern coast-line, which is as warm as the southern coast-line of the Mediterranean, nearly 10° nearer the equator. Thus the whole area of the Black Sea lies, like that of the Mediterranean, between these two summer isotherms; and the evaporation from its surface during the warmer part of the year will consequently be enormous. During the winter months, on the other hand, the Black Sea is exposed to the chilling winds which come down to it from the Arctic regions, sweeping over the snow-covered plains of Russia, without any interruption from high mountain ranges; and nearly the whole of its area lies between the *winter* isotherms of 30° and 40°, the former passing round its northern coast, while the latter passes from the Bosphorus to Poti in Mingrelia. Thus it happens that, notwithstanding their high summer temperature, the northern shores of the Black Sea are more or less blockaded with ice during the winter,—this being most the case where the water is shallowest, and has its salinity lowered by the entrance of rivers. Thus the Sea of Azoff and the Strait of Yenekale are always frozen over, as are also the northern ports between the Crimea and Odessa; while, on the other hand, the harbours of Kaffa and Sebastopol are never closed, and that of Odessa but seldom. It is recorded, however, that in 401 A.D. the surface of the Euxine was almost entirely frozen over, and that when the ice broke up enormous masses were seen floating in the Sea of Marmora for thirty days. In 762 A.D., again, the sea is said to have been frozen from the terminal cliffs of the Caucasus to the mouths of the Dniester, Dnieper, and Danube; and contemporary writers assert that the quantity of snow which fell on the ice rose to the height of from 30 to 40 feet, completely hiding the contour of the shores, and that on the breaking up of the ice in the month of February, the masses of it carried by the current into the Sea of Marmora reunited in one immense sheet across the Hellespont between Sestos and Abydos. No similar occurrence has been subsequently recorded.

The *winds* of the Black Sea are variable, except during summer, when they generally blow from the north-east, while at other seasons southerly or south-westerly winds often prevail. The area is very subject to fogs, which appear to proceed from the precipitation by a cold northerly current of the moisture which has been raised by evaporation from its surface, or has been brought thither by S. or S.W. winds. This sea is remarkable for the rapidity with which violent storms not unfrequently arise, often to subside again with like rapidity.

Drainage Area.—The drainage area of the Black Sea is one of the largest in the world, being estimated at 939,000 square miles, of which 825,000 lie in Europe and 114,000 in Asia. The largest of its rivers is the Danube, which has a total length of 1560 miles, and drains the immense area of 306,000 square miles in the southern portion of Central Europe; its western tributaries lie so near the southern tributaries of the Rhine and the Elbe, that a canal-communication has been established between them, by which small vessels can pass between the North Sea and the Black Sea. The Dnieper has a total length of 1050 miles, and drains an area of 195,500 square miles, chiefly in Western Russia and Russian Poland; its northern tributaries approach the southern tributaries of the Niemen; and a canal-communication has thus been established between the Black Sea and the Baltic. The Don, with a length of 1000 miles, drains an area of 176,500 square miles in South-Eastern Russia, which is conterminous with the basin of the Volga, being separated from it by the Sarpa Hills. Between the Dnieper and Danube, the two smaller rivers, the Bug and the Dniester, traverse respectively 440 and 660 miles in their course, and drain an area of more than 50,000 square miles (ten times greater than that of the Thames). Passing eastwards, we come to the Kuban, which drains the northern slopes of the Caucasus and the plains inhabited by the Black Sea Cossacks, and debouches near the entrance to the Sea of Azoff. But there is no other important river on the eastern coast, most of the water flowing from the mountainous region that separates the Black Sea from the Caspian passing into the latter. The northern slopes of the Armenian mountains furnish tributaries of the River Chouruk, a stream of moderate size, which enters the Black Sea to the east of Trebizond. On the southern coast the principal river is the Kizil Irmak (the *Halys* of the ancients), which drains the large central area of the northern portion of Asia Minor, while towards the western side the River Sakaria drains a large area in the province of Anatolia. Along the whole western coast of the Black Sea, from the Bosphorus to the Danube, no large stream empties itself into the basin,—most of the drainage of Rumilia being carried off by the River Maritza into the Ægean, whilst that of Bulgaria contributes to swell the Danube.

The greater part of the drainage area of the Black Sea, like that of the Baltic, is covered with snow during the winter months, and comparatively little water is then brought down by the rivers. With the return of spring, however, the melting of the snow increases the volume of fresh water poured into the sea, its rivers being at their highest in early summer. By far the larger part of this water is discharged at its north-western border; and the elevation of level thus produced establishes a current that sets along its western shore towards the outlet of the Bosphorus. But as the narrowness of this channel does

not allow it to give immediate passage to the overflow, a portion of the current continues to pass onwards along the southern shore, and, when more than usually strong, even completes the entire circuit of the sea. There are no perceptible tides in this basin.

As might be expected from the foregoing, the salinity of Black Sea water varies (like that of the Baltic) at different periods of the year; but in consequence of the much greater total mass of water contained in the deeper part of this basin, the variation of its salinity is by no means so great as that of Baltic waters,—the usual range of its sp. gr. being from about 1·012 to 1·014, which corresponds to a little less or a little more than half the salinity of ordinary sea water.

The most contradictory notions have prevailed as to the influence of the Euxine waters on those of the Mediterranean,—some writers having represented the rivers of the former as important contributors to the maintenance of the level of the Mediterranean, which the enormous evaporation from that area is always tending to reduce; whilst others assert that the Bosphorus and Dardanelles' currents are entirely due to the agency of wind. A valuable *datum* is afforded by the condition of the Caspian, in the closed basin of which, contracted by a reduction of its level to 80 feet below that of the Black Sea, an equality is now established between the amount of water lost by evaporation and that which is restored by its rivers and by the rainfall on its own surface. The areas of the Caspian and of the Euxine are not very different; and though the axis of the former basin lies north and south, while that of the latter lies east and west,—so that the northern portion of the Caspian is colder, and the southern portion warmer, than the northern and southern portions of the Black Sea,—the annual average temperatures, and consequently the total evaporation, of the two areas cannot differ much. Now, the drainage area of the Volga is equal to that of the Danube, the Dnieper, and the Dniester taken together; the Ural, with the two Transcaucasian rivers, Kur and Araxes, may be considered as equalling the Don; and thus the Bug and the rivers of the Caucasus and Asia Minor may be regarded as furnishing the excess of water discharged into the Black Sea above that which is received by the Caspian. Hence, as the whole of the river and rain water annually discharged into the basin of the Caspian is only sufficient to replace that which is lost by evaporation during the same period, it follows that we may in like manner regard the principal rivers of the Black Sea as only fulfilling the same function; consequently, if the Bosphorus were closed, the water which they pour into the Euxine basin would not produce any elevation of its level, being entirely dissipated by evaporation. Thus the water which the Black Sea has to spare for the Mediterranean only represents the *excess* of its river supply above the total river supply of the Caspian; and that this excess is small in amount appears from the fact that the salinity of the water of the Ægean is not sensibly reduced by it below that of the Mediterranean. But that there is some excess is evident from the consideration that if the evaporation of the Black Sea were merely neutralized by the return of fresh water, its water would have the salinity of that of the great basin with which it is in free communication, instead of containing only about half its proportion. It is further evident, on the other hand, that a continual efflux of the half-salt water of the Black Sea, to be replaced only by the fresh water discharged into its basin by rain and rivers, would in time completely drain that basin of its salt; and as its proportion, though liable to seasonal variation, undergoes no sensible diminution from year to year, it is obvious that the salt which passes out must be replaced by a re-entry of Ægean water. The mode in which this displacement is effected has been recently elucidated by a careful examination of the currents of the Black Sea straits, of which an account will be presently given.

It is during the winter months, when a large proportion of the drainage area of the Black Sea rivers is covered with snow, that the supply of water is at its minimum; but it is then that the evaporation from its surface is also at its minimum; so that there is no reason to suppose that the level of the Black Sea ever falls below that of the Ægean. There can be no reasonable doubt that during the spring and early summer, when the melting of the snows causes the rivers to swell to their highest, the quantity of fresh water thus brought into the basin, being greater than that which is lost by evaporation (as is shown by the general reduction which then takes place in the salinity of its contents), would cause a considerable rise of level, if this were not kept down by the outflow through the straits.

Dardanelles and Bosphorus Currents.—It has been known from very early times that a current, usually of considerable strength, sets outwards through the Black Sea straits during a large part of the year,—its rate being subject, however, to considerable variation in accordance with the breadth of the channel, and also with the force and direction of the wind. Thus, when the N.E. wind is of average strength, the rate of the current at Gallipoli is about 1 knot per hour; whilst in the "Narrows" at Chanak Kaleski it is about 3 knots, increasing with a strong wind to about 4½ knots. In calm weather the out-current of the Dardanelles is usually slack; and if, as sometimes happens even during the general prevalence of N.E. winds, the wind should suddenly blow strongly from the S.W., the surface outflow may be entirely checked. It requires a continuance of strong S.W. wind, however, to reverse its direction; and its rate, when thus reversed, never equals that of the out-current. The Bosphorus current has not been as carefully studied as that of the Dardanelles; but its rate is greater, in accordance with the limitation of its channel, which is scarcely wider at any point than the "Narrows" of the Dardanelles. It continues to run, though at a reduced rate, when there is no wind, and is not known to be ever reversed except in winter after a S.W. gale of long duration. Even then it appears that the reversal is confined to the superficial stratum,—the direction of the sub-surface water-weeds proving that there is still an outflow from the Black Sea into the Ægean. Hence it cannot be reasonably maintained that it is by this occasional and superficial reversal that the immense mass of salt continually being carried outwards by the Bosphorus and Dardanelles currents is restored to the Black Sea basin.

The existence of an inward under-current (although controverted by an authority of weight) has been clearly demonstrated by the recent experimental researches of Captain Wharton, R.N., of H.M. surveying ship "Shearwater." By the use of a "current-drag," so constructed and suspended as always to present a large vertical surface, it was found that when the outward surface-current was at its strongest there was an inward under-current sufficiently strong and rapid to carry inwards the suspending buoy.

The difference in specific gravity of water obtained from different depths was found, in Captain Wharton's investigations (as in those previously made by Dr. Carpenter, in conjunction with Captains Calver and Nares, in the Strait of Gibraltar), to afford, under ordinary circumstances, a very sure indication of the direction of the movement of each stratum,—the heavy water of the Ægean, as a rule, flowing inwards, and the lighter water of the Black Sea flowing outwards. And it was indicated alike by both modes of inquiry that the two strata move in opposite directions, one over the other, with very little intermixture

or retardation,—the transition between them being usually very abrupt. The anomalies occasionally met with seemed due to the prevalence of opposite winds at the two ends of the straits.

Putting aside for the time the influence of wind, the double current of the Black Sea straits may be accounted for as follows :—The excess of fresh water discharged into the basin of the Black Sea is always tending to raise its level; and this produces an outward surface-current, which as regularly tends to keep it down. On the other hand, the reduced salinity of the Euxine column gives to the Ægean column an excess of lateral pressure, which causes its lower stratum to flow back into the Black Sea basin; and as the equality in the amount of salt thus carried back by the under-current to that which escapes by the surface-current is indicated by the maintenance of the standard salinity of Black Sea water, it follows that, as the water which escapes contains about half as much salt in equal measures as the water that enters, the volume of the latter must be about half that of the former.

Now, when the rate of the surface current is augmented by a N.E. wind, there will be not only a more rapid lowering of the Black Sea level, but a tendency to elevation at the Ægean end of the strait; and as this will augment the difference between the downward, and therefore the lateral, pressures of the two columns, the force and volume of the inward under-current will be augmented. When, on the other hand, the S.W. direction of the wind reverses the surface-current, it tends, by piling up the water at the N.E. end of the strait, to augment the weight of the Black Sea column,—the excess of which (notwithstanding its lower salinity) over that of the Ægean column, will then produce a reversal of the under-current also. When the S.W. wind is moderate enough to check the surface outflow without reversing it, the inward under-current will likewise be brought to a stand; for a slight rise in the level of the Black Sea column will cause its greater height to compensate for the greater salinity of the Ægean column, so that their lateral pressures will be equalized.—We have here a "pregnant instance" of the potency of slight differences in level and in salinity to produce even rapid movements of considerable bodies of water; and a strong confirmation is thus afforded by direct observation to the doctrine that differences in density produced by temperature are adequate to give rise to still larger, though slower, movements of the same kind in the great ocean basins.

Zoology.—The basin of the Black Sea is frequented by seals, dolphins, and porpoises; and it is said that in the neighbourhood of the mouths of the Danube the porpoise is perfectly white, so that the Greek mariners, when they catch sight of it, know that they are in the current of that river, although in 30 fathoms water, and many leagues from land. The fish of the Black Sea appear to be for the most part the same as those of the Caspian and the Sea of Aral. Its northern rivers bring into it the sturgeon, sterlet, and other fresh-water fish, which can live in and near their estuaries. On the other hand, its waters are elsewhere salt enough for the mackerel, whiting, mullet, turbot, and sole. The *pelamys* spoken of by Strabo as issuing from the *Mæotis* (Sea of Azoff) in shoals, and as following the coast of Asia, is still abundant; though commonly spoken of as the herring, it seems to be a large sprat. The principal fish that enters this basin from the Mediterranean is the tunny, which comes into the Black Sea in large numbers at the spawning season. The other inhabitants of the Black Sea have not been especially studied; but it may be noted that a species of *Teredo* is very common and destructive both to ships and to wooden harbour-works, and that it is not confined to the salter waters of the basin, but frequents the estuaries where the water is almost fresh. (W. B. C.)

BLACKBIRD (*Turdus merula*), belongs to the *Turdidæ* or Thrushes, a family of Dentirostral Birds. The plumage of the male is of a uniform black colour, that of the female various shades of brown, while the bill of the male, especially during the breeding season, is of a bright gamboge yellow. The blackbird is of a shy and restless disposition, courting concealment, and rarely seen in flocks, or otherwise than singly or in pairs, and taking flight when startled with a sharp shrill cry. It builds its nest in March, or early in April, in thick bushes or in ivy-clad trees, and usually rears two broods each season. The nest is a neat structure of coarse grass and moss, mixed with earth, and plastered internally with mud, and here the female lays from four to six eggs of a blue colour speckled with black. The blackbird feeds chiefly on fruits, worms, the larvæ of insects, and snails, extracting the latter from their shells by dexterously chipping them on stones; and though it is generally regarded as an enemy of the garden, it is probable that the amount of damage done by it to the fruit is amply compensated for by its undoubted services as a vermin-killer. The notes of the blackbird are rich and full, but monotonous as compared with those of the song-thrush. Like many other singing birds it is, in the wild state, a mocking-bird, having been heard to imitate the song of the nightingale, the crowing of a cock, and even the cackling of a hen. In confinement it can be taught to whistle a variety of tunes, and even to imitate the human voice. It is found throughout Europe, Palestine, and the northern parts of Africa; and Darwin states that he observed it as far west as the Azores. Individuals reared in Britain, it is said, do not migrate; but annually great flocks arrive on the eastern shores of England from more northern countries, remaining for a few days only, and then proceeding southward.

BLACKBURN, a large manufacturing town and municipal borough of England, situated on a stream called, in *Domesday Book*, the Blackeburn, but now only known as "The Brook," in the north-eastern division of the county of Lancaster, 209 miles from London by railway, 15 E. of Preston, and 30 N.N.W. of Manchester. Besides its numerous churches and chapels, the public buildings of Blackburn comprise a large town-hall, finished in 1856, a market-house, an exchange, built in 1865, a county court (1863), public baths (1864), and, outside the town, an infirmary (1862). A public park of about 50 acres was opened in 1857. Since about 1865 a variety of extensive and important improvements have been effected in the general condition of the town, which is now well paved and lighted, has an elaborate system of drainage, and receives an abundant supply of water. Previous to that date the so-called streets were, over a large area, almost useless for purposes of traffic. The staple trade of Blackburn has long been the manufacture of cotton, for the development of which a great deal was done by some natives of the town, such as Peel and Hargreaves, in the last century. The subordinate branches include woollen factories, engineering works, iron foundries, and breweries. In 1871 there were employed in the cotton factories 14,220 men and 17,075 women, of twenty years of age and upwards; the engineering works gave employment to 356 men, and the iron manufacture to 794. Coal, and lime, and building stone are abundant in the neighbouring district, which is, however, very far from fertile. The Leeds and Liverpool Canal passes the town, which has also extensive railway communication. Blackburn is a place of some antiquity, and its parish church of St Mary's (for the most part taken down in 1813), dated from before the Norman Conquest. In was for a time the chief town of a district known as Blackburnshire, and as early as the reign of Elizabeth ranked as a flourishing market town. About

the middle of the 17th century it became famous for its "checks," which were afterwards superseded by a similar linen-and-cotton fabric known as "Blackburn greys." A charter of incorporation was obtained in 1851, when W. H. Hornby, one of the largest cotton manufacturers of the place, was elected first mayor. The population of the town, which was only about 5000 in 1790, had increased by 1801 to 11,980. In 1861 there were 11,306 inhabited houses in the municipal borough; and by the census of 1871 the number had increased to 14,690. In the former year the population of the municipal borough was 63,126, and in 1871 it amounted to 76,339 (males 36,099, females 40,240), while the parliamentary burgh with its extended boundaries contained 82,928 inhabitants. Blackburn returns two members to parliament.

BLACKCOCK (*Tetrao tetrix*), a Gallinaceous Bird belonging to the family *Tetraonidæ* or Grouse, the female of which is known as the Grey Hen and the young as Poults. In size and plumage the two sexes offer a striking contrast, the male weighing about 4 lb, its plumage for the most part of a rich glossy black shot with blue and purple, the lateral tail feathers curved outwards so as to form, when raised, a fan-like crescent, and the eyebrows destitute of feathers and of a bright vermilion red. The female, on the other hand, weighs only 2 lb, its plumage is of a russet brown colour irregularly barred with black, and its tail feathers are of the ordinary form or but slightly forked. The males are polygamous, and during autumn and winter associate together, feeding in flocks apart from the females; but with the approach of spring they separate, each selecting a locality for itself, from which it drives off all intruders, and where morning and evening it seeks to attract the other sex by a display of its beautiful plumage, which at this season attains its greatest perfection, and by a peculiar cry, which Selby describes as "a crowing note, and another similar to the noise made by the whetting of a scythe." Its nest, composed of a few stalks of grass, is built on the ground, usually beneath the shadow of a low bush or a tuft of tall grass, and here the female lays from six to ten eggs of a dirty-yellow colour speckled with dark brown. The blackcock then rejoins his male associates, and the female is left to perform the labours of hatching and rearing her young brood. The plumage of both sexes is at first like that of the female, but after moulting the young males gradually assume the more brilliant plumage of their sex. There are also many cases on record, and specimens may be seen in the principal museums, of old female birds assuming, to a greater or less extent, the plumage of the male. The blackcock is very generally distributed over the highland districts of Northern and Central Europe, and in some parts of Asia. It is found on the principal heaths in the south of England, but is specially abundant in the Highlands of Scotland, where great numbers are killed annually during the statutory shooting season, which commences on August 20 and extends to December 10. The bird does not occur in Ireland, and all attempts that have hitherto been made to naturalize it there have failed, although it now thrives and breeds in the south-west of Scotland within 21 miles of the Irish coast. During summer, blackcock reside chiefly on the ground, feeding on seeds, the young shoots of heath, and insects; in autumn they regularly frequent the stubble fields; but in winter they perch on trees, especially the birch and fir, the tender shoots of which then form their principal food.

BLACKLOCK, Thomas, a Scottish poet and divine, was born of humble but respectable parents at Annan, in Dumfriesshire, in 1721. When not quite six months old he lost his sight by the smallpox. Under this misfortune, his father and friends endeavoured to amuse him as he grew up by reading to him various books,—among others, the works of Milton, Spenser, Prior, Pope, and Addison. Shortly after the death of his father, which took place in 1740, some of Blacklock's poems began to be handed about among his acquaintances and friends, and a few specimens were brought under the notice of Dr Stevenson of Edinburgh, who was struck by their merits, and formed the design of giving the author a classical education. Blacklock, in consequence, was enrolled a student of divinity in the university of Edinburgh in 1741, and continued his studies under the patronage of Dr Stevenson till 1745, when he retired to Dumfries, and resided there until the close of the civil war. When peace had been restored, he returned to the university, and during this residence in Edinburgh he made the acquaintance of several literary men, in particular of Hume, who was extremely useful to him in the publication by subscription of the 4to edition of his poems in 1756. Two editions in 8vo had previously been published at Edinburgh, in 1746 and in 1754. After applying closely for a considerable time to the study of theology, he was in 1762 ordained minister of the church of Kirkcudbright; but owing to an opposition to the appointment on the part of the parishioners, he resigned his right to the living, and accepted a moderate annuity in its stead. In 1767 the degree of doctor in divinity was conferred on him by Marischal College, Aberdeen. He died on the 7th of July 1791. His poems are pleasing but weak effusions, and there is nothing remarkable about them save that they were written by one who laboured under the misfortune of blindness.

BLACKMORE, Sir Richard, a physician, and voluminous writer of theological and poetical works, was born in Wiltshire about 1650. He was educated at Westminster and Oxford, graduated in medicine at Padua, and settled in practice as a physician in London. Having early declared in favour of the Revolution, he was in 1697 chosen one of King William's physicians in ordinary, and received the honour of knighthood. On Queen Anne's accession, Sir Richard was also appointed one of her physicians, which office he held for some time. He died on the 9th October 1729. Blackmore had a passion for writing epics. No fewer than seven long poems were published by him between 1695 and 1723. The first was *Prince Arthur*, in 10 books; then followed *King Arthur*, in 12 books; *Eliza*, in 10; *Creation*, in 7; *Redemption*, in 6; *Nature of Man*, in 3; and *Alfred*, in 12. Of these *Creation*, a philosophic poem directed against the atomic theories of Epicurus and Lucretius, and intended to refute the atheism of Vanini, Hobbes, and Spinosa, and to unfold the intellectual philosophy of Locke, has been the most favourably received. Addison and Johnson praised it highly, the latter anticipating that this poem would transmit the author to posterity "among the first favourites of the English muse." It would be hard to find grounds for this expectation, which has certainly not been realized. The poem, like everything else that Blackmore wrote, is dull and tedious, and exhibits in every part the author's want of true poetic sensibility and taste.

BLACKPOOL, a seaside town of England, in Lancashire, situated on the coast to the north of the estuary of the Ribble, about 20 miles W. of Preston by rail. It is largely frequented as a bathing-place. A good sandy beach, bracing air, and a fine view, are its chief attractions. In the end of last century it was a mere hamlet, but since then it has gradually increased. It has two churches, two market-halls, a court-house, and assembly rooms. The parade affords a fine promenade. A new pier was built in 1866. Population in 1871, 6100.

BLACKSTONE, Sir William, an eminent English jurist, was born at London, July 10, 1723. He was a posthumous child, and his mother died before he was twelve

years old. From his birth the care of his education was undertaken by his maternal uncle Thomas Bigg, an eminent surgeon in London. When about seven years old he was sent to the Charterhouse School, and in 1735 he was admitted upon the foundation there by the nomination of Sir Robert Walpole. His progress was so rapid that at the age of fifteen he was at the head of the school, and qualified to be removed to the university, and he was accordingly entered a commoner at Pembroke College, Oxford, on the 30th of November 1738. At the time of entering he held an exhibition from his school, and in February following he was elected by his college to one of Lady Holford's exhibitions for Charterhouse scholars. He was a diligent student, devoting himself specially though not exclusively to the Greek and Roman poets. At the early age of twenty he compiled a treatise, entitled *Elements of Architecture*, intended for his own use only and not for publication, which was highly spoken of by those who were permitted to read it.

Having made choice of the profession of the law, he was entered in the Middle Temple, November 20, 1741. In a copy of verses of considerable merit, afterwards published by Dodsley in the fourth volume of his Miscellanies, entitled *The Lawyer's Farewell to his Muse*, he gave utterance to the regret with which he abandoned the pleasing pursuits of his youth for severer studies. Besides this, several fugitive pieces were at times communicated by him to his friends; and he left, but not with a view to publication, a small collection of juvenile pieces, consisting of both original poems and translations. Some notes which just before his death he communicated to Steevens, and which were inserted by the latter in his last edition of Shakespeare's works, show how well he understood the meaning and relished the beauties of his favourite English poet.

In November 1743 he was elected into the society of All Souls' College. In the November following he spoke the anniversary speech in commemoration of Archbishop Chichele, the founder, and the other benefactors to that house of learning, and was at the same time admitted actual fellow. From this period he divided his time between the university and the Temple, where he took chambers in order to attend the courts. In the former he pursued his academical studies, and on the 12th of June 1745 took the degree of bachelor of civil law; in the latter he applied himself closely to his profession, both in the hall and in his private studies; and on the 28th of November 1746 he was called to the bar. Though but little known or distinguished in Westminster Hall, he was actively employed, during his occasional residences at the university, in taking part in the internal management of his college. In May 1749, as a small reward for his services, and to give him further opportunities of advancing the interests of the college, Blackstone was appointed steward of its manors. In the same year, on the resignation of his uncle, Seymour Richmond, he was elected recorder of the borough of Wallingford in Berkshire. On the 26th of April 1750 he commenced doctor of civil law, and thereby became a member of the convocation, which enabled him to extend his views beyond the narrow circle of his own society, to the benefit of the university at large. In the summer of 1753 he took the resolution of wholly retiring to his fellowship and an academical life, still continuing the practice of his profession as a provincial counsel.

His lectures on the laws of England appear to have been an early and favourite idea; for in the Michaelmas term immediately after he quitted Westminster Hall, he entered on the duty of reading them at Oxford; and we are told by the author of his *Life*, that even at their commencement, the high expectations formed from the acknowledged abilities of the lecturer attracted to these lectures a very crowded class of young men of the first families, characters, and hopes. Bentham, however, declares that he was a "formal, precise, and affected lecturer—just what you would expect from the character of his writings—cold, reserved, and wary, exhibiting a frigid pride." It was not till the year 1758 that the lectures in the form they now bear were read in the university. Mr Viner having by his will left not only the copyright of his abridgment, but other property to a considerable amount, to the University of Oxford, in order to found a professorship, fellowships, and scholarships of common law, Blackstone was on the 20th of October 1758 unanimously elected Vinerian professor; and on the 25th of the same month he read his first introductory lecture, which he published at the request of the vice-chancellor and heads of houses, and afterwards prefixed to the first volume of his celebrated *Commentaries*. It is doubtful whether the *Commentaries* were originally intended for the press; but many imperfect and incorrect copies having got into circulation, and a pirated edition of them being either published or preparing for publication in Ireland, the author thought proper to print a correct edition himself, and in November 1765 published the first volume, under the title of *Commentaries on the Laws of England*. The remaining parts of the work were given to the world in the course of the four succeeding years. It ought to be remarked, that before this period the reputation which his lectures had deservedly acquired for him had induced him to resume his practice in Westminster Hall; and, contrary to the general order of the profession, he who had quitted the bar for an academic life was sent back from the college to the bar with a considerable increase of business. He was likewise elected to parliament, first for Hindon, and afterwards for Westbury in Wilts; but in neither of these departments did he equal the expectations which his writings had raised. The part he took in the Middlesex election drew upon him the attacks of some persons of ability in the senate, and likewise a severe animadversion from the caustic pen of *Junius*. This circumstance probably strengthened the aversion he professed to parliamentary attendance, "where," he said, "amidst the rage of contending parties, a man of moderation must expect to meet with no quarter from any side." In 1770 he declined the place of solicitor-general; but shortly afterwards, on the promotion of Sir Joseph Yates to a seat in the court of Common Pleas, he accepted a seat on the bench, and on the death of Sir Joseph succeeded him there also. Blackstone died on the 14th February 1780, in the fifty-seventh year of his age.

The design of the *Commentaries* is exhibited in his first Vinerian lecture printed in the introduction to them. The author there dwells on the importance of noblemen, gentlemen, and educated persons generally being well acquainted with the laws of the country; and his treatise, accordingly, is as far as possible a popular exposition of the laws of England. Falling into the common error of identifying the various meanings of the word law, he advances from the law of nature (being either the revealed or the inferred will of God) to municipal law, which he defines to be a rule of civil conduct prescribed by the supreme power in a state commanding what is right and prohibiting what is wrong. On this definition he founds the division observed in the *Commentaries*. The objects of law are rights and wrongs. Rights are either rights of persons or rights of things. Wrongs are either public or private. These four headings form respectively the subjects of the four books of the *Commentaries*.

Blackstone was by no means what would now be called a scientific jurist. He has only the vaguest possible grasp of the elementary conceptions of law. He evidently regards the law of gravitation, the law of nature, and the law of

England, as different examples of the same principle—as rules of action or conduct imposed by a superior power on its subjects. He propounds in terms a fallacy which is perhaps not yet quite expelled from courts of law, viz., that municipal or positive laws derive their validity from their conformity to the so-called law of nature or law of God. "No human laws," he says, "are of any validity if contrary to this." His distinction between rights of persons and rights of things, implying, as it would appear, that things as well as persons have rights, is attributable to a misunderstanding of the technical terms of the Roman law. In distinguishing between private and public wrongs (civil injuries and crimes) he fails to seize the true principle of the division. Austin, who accused him of following slavishly the method of Hale's *Analysis of the Law*, declares that he "blindly adopts the mistakes of his rude and compendious model; missing invariably, with a nice and surprising infelicity, the pregnant but obscure suggestions which it proffered to his attention, and which would have guided a discerning and inventive writer to an arrangement comparatively just." By the want of precise and closely-defined terms, and his tendency to substitute loose literary phrases, he falls occasionally into irreconcilable contradictions. Even in discussing a subject of such immense importance as equity, he hardly takes pains to discriminate between the legal and popular senses of the word, and, from the small place which equity jurisprudence occupies in his arrangement, he would scarcely seem to have realized its true position in the law of England. Subject, however, to these strictures the completeness of the treatise, its serviceable if not scientific order, and the power of lucid exposition possessed by the author demand emphatic recognition. Blackstone's defects as a jurist are more conspicuous in his treatment of the underlying principles and fundamental divisions of the law than in his account of its substantive principles.

Blackstone by no means confines himself to the work of a legal commentator. It is his business, especially when he touches on the framework of society, to find a basis in history and reason for all our most characteristic institutions. There is not much either of philosophy or fairness in this part of his work. Whether through the natural conservatism of a lawyer, or through his own timidity and subserviency as a man and a politician, he is always found to be a specious defender of the existing order of things. Bentham accuses him of being the enemy of all reform, and the unscrupulous champion of every form of professional chicanery. Austin says that he truckled to the sinister interests and mischievous prejudices of power, and that he flattered the overweening conceit of the English in their own institutions. He displays much ingenuity in giving a plausible form to common prejudices and fallacies; but it is by no means clear that he was not imposed upon himself. More undeniable than the political fairness of the treatise is its merit as a work of literature. It is written in a most graceful and attractive style, and although no opportunity of embellishment has been lost, the language is always simple and clear. Whether it is owing to its literary graces, or to its success in flattering the prejudices of the public to which it was addressed, the influence of the book in England has been extraordinary. Not lawyers only, and lawyers perhaps even less than others, accepted it as an authoritative revelation of the law. It performed for educated society in England much the same service as was rendered to the people of Rome by the publication of their previously unknown laws. It is more correct to regard it as a handbook of the law for laymen than as a legal treatise; and as the first and only book of the kind in England it has been received with somewhat indiscriminating reverence. It is certain that a vast amount of the constitutional sentiment of the country has been inspired by its pages. To this day Blackstone's criticism of the English constitution would probably express the most profound political convictions of the majority of the English people. Long after it has ceased to be of much practical value as an authority in the courts, it remains the arbiter of all public discussions on the law or the constitution. On such occasions the *Commentaries* are apt to be construed as strictly as if they were a code. It is amusing to observe how much importance is attached to the *ipsissima verba* of a writer who aimed more at presenting a picture intelligible to laymen than at recording the principles of the law with technical accuracy of detail. (E. R.)

BLAINVILLE, Henri-Marie Ducrotay de, a distinguished naturalist, was born at Arques, near Dieppe, Sept. 12, 1777. About the year 1795 he entered the school of design at Rouen, but after a very short time he went to Paris, where he became a pupil of Vincent the painter. Attracted by the lectures of Cuvier and other eminent professors in the College of France, he commenced the study of anatomy, and in 1808 he took the degree of M.D. He now devoted himself to the study of natural history, particularly the department of myology, and he soon attracted the attention of Cuvier, who engaged him to draw some figures for one of his works, and to carry out some of the practical work of anatomy. He was also chosen by that illustrious professor to supply his place on occasions at the College of France and at the Athenæum, and in 1812 he obtained the vacant chair of anatomy and zoology in the Faculty of Sciences at Paris. His somewhat irascible disposition was probably one cause of the subsequent estrangement between him and Cuvier, which ended in an open and irreconcilable enmity. In 1825 Blainville was admitted a member of the Academy of Sciences; and in 1830 he was appointed to succeed Lamarck in the chair of natural history at the museum. This he resigned in 1832, being appointed on the death of Cuvier to the chair of comparative anatomy, which he continued to occupy for the space of eighteen years, and in the conduct of which he proved himself no unworthy successor to his great teacher. Blainville was found dead in a railway carriage while travelling between Rouen and Caen, May 1, 1850.

Besides a great variety of separate memoirs, he was the author of *Prodrome d'une Nouvelle Distribution Methodique du Regne Animal*, 1816; *Osteographie ou Description Iconographique Comparée du Squelette*, &c; *Faune Française*, 1821 1830; *Cours de Physiologie Générale et Comparée*, 1833; *Manuel de Malacologie et de Conchyliologie*, 1825-1827; *Histoire des Sciences Naturelles au Moyen Age*, 1845.

BLAIR, or Port-Blair, the chief place in the convict settlement of the Andaman Islands in the Indian Ocean, is situated on the south-east shore of the South Andaman Island, in 11° 42′ N. lat. and 93° E. long. In 1789 it was selected as a convict settlement, under orders of the Indian Government, by Lieutenant Blair, R.N., whose name the port bears. It possesses one of the best harbours in Asia, while its central position in the Bay of Bengal gives it immense advantage as a place of naval rendezvous for military operations in this part of the world. For further particulars see Andaman Islands.

BLAIR, Dr Hugh, was born April 7, 1718, at Edinburgh, where his father was a merchant. He entered Edinburgh University in 1730 and won the favourable notice of Professor Stevenson by an essay on the Beautiful, written for the logic class in his sixteenth year. On taking the degree of M.A. in 1739, he printed a thesis *De Fundamentis et Obligatione Legis Naturæ*, which contains an outline of the moral principles afterwards unfolded in his sermons. He was licensed to preach in 1741, and in a few months the earl of Leven, hearing of his eloquence,

presented him to the parish of Collessie in Fife. In 1743 he was elected to the second charge of the Canongate Church, Edinburgh, where he performed the pastoral duties with great success, until removed to Lady Yester's, one of the city churches, in 1754. He married his cousin, Katherine Bannatyne, in 1748, and by her had a son, who died in infancy, and a daughter who lived to her twenty-first year. In 1757 the University of St Andrews conferred on him the degree of D.D., and in the following year he was promoted to the High Church, Edinburgh, the most important charge in Scotland. In 1759 he commenced, under the patronage of Lord Kames, to deliver a course of lectures on composition, the success of which led to the foundation of a chair of rhetoric and belles lettres in the Edinburgh University. To this chair he was appointed in 1762, with a salary of £70 a year. Having long taken interest in the Celtic poetry of the Highlands, he published in 1763 a laudatory *Dissertation* on Macpherson's *Ossian*, of which he maintained the authenticity. This critique, after being greatly overrated at the time, has now fallen into neglect. In 1777 the first volume of his *Sermons* appeared. It was succeeded by other four volumes, all of which met with the greatest success. Dr Samuel Johnson praised them warmly. "I love Blair's *Sermons*," Johnson said, "his doctrine is the best limited, the best expressed; there is the most warmth without fanaticism, the most rational transport." The *Sermons* were translated into almost every language of Europe, and in 1780, to signify the royal approbation, George III. conferred upon him a pension of £200 a year. In 1783 he retired from his professorship and published his *Lectures on Rhetoric* which he had carefully revised, and which have been frequently reprinted. He died, after a brief illness, on the 27th December 1801. In the church Blair belonged to the "moderate" or latitudinarian party, and his *Sermons* have been objected to as deficient in doctrinal definiteness. His once brilliant reputation is now becoming forgotten. His works display little originality, but are written in a flowing and elaborate style; and his *Rhetoric*, although inferior to Campbell's, and wanting in research and depth of thought, is unworthy of the neglect it has met with.

BLAIR, ROBERT, author of the well-known poem entitled *The Grave*, was the eldest son of the Rev. Robert Blair, of Edinburgh. He was probably born at Edinburgh about the year 1700, and at the university of that city he received the elements of a classical education. He afterwards spent some time on the Continent. Upon his return he took orders, and in 1731 was ordained minister of Athelstaneford, in East Lothian, where he spent the remainder of his life. He died of fever, February 4, 1746, and was succeeded in his living by John Home, the author of *Douglas*. His fourth son became lord-president of the Court of Session. Blair wrote several other pieces besides *The Grave*; but that poem alone constitutes his title to rank as a poet. It consists of a succession of descriptions and reflections, which have no other connection except what they may derive from their relation to a common subject, but these are interspersed with striking allusions, picturesque imagery, touches of a rude though effective pathos, and a vein of sentiment at once natural and just. The rhythm is often harsh, and the versification frequently devoid of correctness, harmony, and grace; but it has nevertheless a masculine vigour and freshness about it, which more than atone for the defects in the finishing; while, in certain moods of the mind, the air of deep and almost misanthropical melancholy diffused over the whole proves highly touching and impressive. Campbell, in the *Pleasures of Hope*, has borrowed, with a slight variation, a line from this poem—

> "Its visits,
> Like those of angels, short and far between."

The vigorous, though occasionally rather forced, poetic conceptions of the author of *The Grave*, were finely illustrated in Cromek's edition, published in 1808, by the grandly wild designs of William Blake, engraved by the delicate burin of Schiavonetti. *The Grave* was first printed at London in 1743.

BLAKE, ROBERT, the famous English admiral of the Commonwealth, was born at Bridgwater in Somersetshire, in August 1598. His birth thus falls in the year before that of Cromwell; their lives ran parallel in the service of their country; their characters present many points of likeness; and they died within a few months of each other. Blake was the eldest son of a well-to-do merchant, and received his early education at the grammar school of Bridgwater. At the age of sixteen he was sent to Oxford, entering at first St Alban's Hall, but removing afterwards to Wadham College, then recently founded by his father's friend, Nicholas Wadham. He remained at the university till 1623, and though certainly not wanting in ability or in diligence, he missed, for some reason not clearly ascertained, such college preferment as he naturally aimed at. From Oxford, after taking his degree of M.A., he returned to his father's house, where, through the memorable and troubled years which followed, he led a quiet and retired life. His thorough honesty, his public spirit and disinterestedness, his courageous utterance of what he thought of the court and the church, of shipmoney and the High Commission Court and the licence of the times, made him a man of mark among his neighbours. And when, after eleven years of kingship without parliaments, a parliament was summoned to meet in April 1640, Blake was elected by the Presbyterian party to represent his native borough. This parliament, named "the Short," was dissolved in three weeks, and the career of Blake as a politician was suspended. Two years later the inevitable conflict began. Blake declared for the Parliament; and thinking, says Johnson, a bare declaration for right not all the duty of a good man, he raised a troop of horse in his county, and rendered such efficient service, that in 1643 he was entrusted with the command of one of the forts of Bristol. This he stoutly held during the siege of the town by Prince Rupert, and was near being hung for continuing his resistance after the governor had capitulated. In the following year Colonel Blake took Taunton by surprise, and notwithstanding its imperfect defences and inadequate supplies, held the town for the Parliament against two sieges by the Royalists, until July 1645, when it was relieved by Fairfax. Blake did not approve of the trial and execution of Charles I.; but he adhered to the Parliamentary party after the king's death, and within a month (February 1649) was appointed, with Colonels Dean and Popham, to the command of the fleet, under the title of General of the Sea. In April he was sent in pursuit of Prince Rupert, who with the Royalist fleet had entered the harbour of Kinsale in Ireland. There he blockaded the Prince for six months; and when the latter, in want of provisions, and hopeless of relief, succeeded in making his escape with the fleet and in reaching the Tagus, Blake followed him thither, and again blockaded him for some months. The king of Portugal refusing permission for Blake to attack his enemy, the latter made reprisals by falling on the Portuguese fleet, richly laden, returning from Brazil. He captured seventeen ships and burnt three, bringing his prizes home without molestation. After revictualling his fleet, he sailed again, captured a French man-of-war, and then pursued Prince Rupert once more to the harbour of Carthagena. The Spanish governor would not allow him to violate the peace of a neutral port, and he therefore withdrew. In January 1651 he at last attacked the Royalist fleet in Malaga harbour, and destroyed the whole

with the exception of two ships. In consequence of the Portuguese protest against his proceedings, a formal investigation was instituted in England, which resulted in the approval of the home authorities. The thanks of Parliament were voted to Blake, and he was appointed warden of the Cinque Ports. He was continued in his office of admiral and general of the sea; and in May following he took, in conjunction with Ayscue, the Scilly Islands. For this service the thanks of Parliament were again awarded him, and he was soon after made a member of the Council of State. In 1652 war broke out with the Dutch, who had made great preparations for the conflict. In March the command of the fleet was given to Blake for nine months; and in the middle of May the Dutch fleet of forty-five ships, led by their great admiral Van Tromp, appeared in the Downs. Blake, who had only twenty ships, sailed to meet them, and the battle took place off Dover on May 19. The Dutch were defeated in an engagement of four or five hours, lost two ships, and withdrew under cover of darkness. Attempts at accommodation were made by the States, but they failed. Early in July war was formally declared, and in the same month Blake captured a large part of the Dutch fishery-fleet and the twelve men-of-war that formed their convoy. On September 28, Blake and Penn again encountered the Dutch fleet, now commanded by De Ruyter and De Witt, in the Downs, defeated it, and chased it for two days. The Dutch took refuge in Goree. A third battle was fought near the end of November. By this time the ships under Blake's command had been reduced in number to forty, and nearly the half of these were useless for want of seamen. Van Tromp, who had been reinstated in command, appeared in the Downs, with a fleet of eighty ships besides ten fire-ships. Blake, nevertheless, risked a battle, but was defeated, and withdrew into the Thames. It was in his first elation at this victory that Van Tromp carried the broom at his mast-head in his passage through the Channel, as a pledge of his determination to sweep the English off the seas. His bravado was speedily avenged. The English fleet having been refitted, put to sea again in February 1653; and on the 18th, Blake, at the head of eighty ships, encountered Van Tromp in the Channel. The Dutch force, according to Clarendon, numbered 100 ships of war, but according to the official reports of the Dutch, only seventy. The battle was severe, and continued through three days, the Dutch however retreating, and taking refuge in the shallow waters off the French coast. In this action Blake was severely wounded. In the change of Government introduced by the dismissal of the Long Parliament by Cromwell (April 1653) Blake did not interfere. "It is not," he said, "the business of a seaman to mind state affairs, but to hinder foreigners from fooling us." The three English admirals put to sea again in May; and on June 3d and 4th another battle was fought near the North Foreland. On the first day Dean and Monk were repulsed by Van Tromp; but on the second day the scales were turned by the arrival of Blake, and the Dutch retreated to the Texel. Ill health now compelled Blake to retire from the service for a time, and he did not appear again on the seas for about eighteen months; meanwhile he sat as a member of the Little Parliament (Barebones's). In November 1654 he was selected by Cromwell to conduct a fleet to the Mediterranean to exact compensation from the Duke of Tuscany, the knights of Malta, and the piratical states of North Africa, for wrongs done to English merchants. This mission he executed with his accustomed spirit and with complete success. Tunis alone dared to resist his demands, and Tunis paid the penalty of the destruction of its two fortresses by English guns. In the winter of 1655–56, war being declared against Spain, Blake was sent to cruise off Cadiz and the neighbouring coasts, to intercept the Spanish shipping. One of his captains captured a part of the Plate fleet in September 1656. In April 1657 Blake, then in very ill health, suffering from dropsy and scurvy, and anxious to have assistance in his arduous duties, heard that the Plate fleet lay at anchor in the bay of Santa Cruz, in the island of Teneriffe. The position was a very strong one, defended by a castle and several forts with guns. Under the shelter of these lay a fleet of sixteen ships drawn up in crescent order. Captain Stayner was ordered to enter the bay and fall on the fleet. This he did. Blake followed him. Broadsides were poured into the castle and the forts at the same time; and soon nothing was left but ruined walls and charred fragments of burnt ships. The wind was blowing hard into the bay; but suddenly, and fortunately for the heroic Blake, it shifted, and carried him safely out to sea. "The whole action," says Clarendon, "was so incredible that all men who knew the place wondered that any sober man, with what courage soever endowed, would ever have undertaken it; and they could hardly persuade themselves to believe what they had done; while the Spaniards comforted themselves with the belief that they were devils and not men who had destroyed them in such a manner." The English lost one ship and 200 men killed and wounded. The thanks of Parliament were voted to officers and men; and a very costly jewel (diamond ring) was presented to Blake, "as a testimony," says Cromwell in his letter of June 10th, "of our own and the Parliament's good acceptance of your carriage in this action." "This was the last action of the brave Blake." After again cruising for a time off Cadiz, his health failing more and more, he was compelled to make homewards before the summer was over. He died at sea, but within sight of Plymouth, August 17, 1657. His body was brought to London and embalmed, and after lying in state at Greenwich House was interred with great pomp and solemnity in Westminster Abbey. In 1661 Charles II. disgraced himself by ordering the exhumation of Blake's body, with those of the mother and daughter of Cromwell and several others. They were cast out of the abbey, and were reburied in the churchyard of St Margaret's. "But that regard," says Johnson, "which was denied his body had been paid to his better remains, his name and his memory. Nor has any writer dared to deny him the praise of intrepidity, honesty, contempt of wealth, and love of his country." Clarendon bears the following testimony to his excellence as a commander:—"He was the first man that declined the old track, and made it apparent that the science might be attained in less time than was imagined. He was the first man who brought ships to contemn castles on the shore, which had ever been thought very formidable, but were discovered by him to make a noise only, and to fright those who could be rarely hurt by them." A life of Blake is included in the work entitled *Lives, English and Foreign.* Dr Johnson wrote a short life of him, and in 1852 appeared Mr Hepworth Dixon's fuller narrative, *Robert Blake, Admiral and General at Se* (W. L. R. C.)

BLAKE, WILLIAM, poet and painter, was born in London, on 28th November 1757. His father, James Blake, kept a hosier's shop in Broad Street, Golden Square; and from the scanty education which the young artist received, it may be judged that the circumstances of the family were not very prosperous. For the facts of William Blake's early life the world is indebted to a little book, called *A Father's Memoirs on a Child*, written by Dr Malkin, and published in 1806. Here we learn that young Blake quickly developed a taste for design, which his father appears to have had sufficient intelligence to recognize and assist by every means in his power. At the age of ten the boy was sent to a drawing school kept by Mr Pars

in the Strand, and at the same time he was already cultivating his own taste by constant attendance at the different art sale rooms, where he was known as the "little connoisseur." Here he began to collect prints after Michel Angelo, and Raphael, Durer, and Hemskerk, while at the school in the Strand he had the opportunity of drawing from the antique. After four years of this preliminary instruction Blake entered upon another branch of art study. In 1777 he was apprenticed to James Basire, an engraver of repute, and with him he remained seven years. His apprenticeship had an important bearing on Blake's artistic education, and marks the department of art in which he was made technically proficient. In 1778, at the end of his apprenticeship, he proceeded to the school of the Royal Academy, where he continued his early study from the antique, and had for the first time an opportunity of drawing from the living model.

This is in brief all that is known of Blake's artistic education. That he ever, at the academy or elsewhere, systematically studied painting we do not know; but that he had already begun the practice of water colour for himself is ascertained. So far, however, the course of his training in art schools, and under Basire, was calculated to render him proficient only as a draughtsman and an engraver. He had learned how to draw, and he had mastered besides the practical difficulties of engraving, and with these qualifications he entered upon his career. In 1780 he exhibited a picture in the Royal Academy Exhibition, conjectured to have been executed in water colours, and he continued to contribute to the annual exhibitions up to the year 1808. In 1782 he married Catherine Boucher, the daughter of a market-gardener at Battersea, with whom he lived always on affectionate terms, and the young couple after their marriage established themselves in Green Street, Leicester Fields. Blake had already become acquainted with some of the rising artists of his time, amongst them Stothard, Flaxman, and Fuseli, and he now began to see something of literary society. At the house of the Rev. Henry Mathew, in Rathbone Place, he used to recite and sometimes to sing poems of his own composition, and it was through the influence of this gentleman, combined with that of Flaxman, that Blake's first volume of poetry was printed and published in 1783. From this time forward the artist came before the world in a double capacity. By education as well as native talent, he was pledged to the life of a painter, and these *Poetical Sketches*, though they are often no more than the utterances of a boy, are no less decisive in marking Blake as a future poet.

For a while the two gifts are exhibited in association. To the close of his life Blake continued to print and publish, after a manner of his own, the inventions of his verse illustrated by original designs, but there is a certain period in his career when the union of the two gifts is peculiarly close, and when their service to one another is unquestionable. In 1784 Blake, moving from Green Street, set up in company with a fellow-pupil, Parker, as print-seller and engraver next to his father's house in Broad Street, Golden Square, but in 1787 this partnership was severed, and he established an independent business in Poland Street. It was from this house, and in 1787, that the *Songs of Innocence* were published, a work that must always be remarkable for beauty both of verse and of design, as well as for the singular method by which the two were combined and expressed by the artist. Blake became in fact his own printer and publisher. He engraved upon copper, by a process devised by himself, both the text of his poems and the surrounding decorative design, and to the pages printed from the copper plates an appropriate colouring was afterwards added by hand. The poetic genius already discernible in the first volume of *Poetical Sketches* is here more decisively expressed, and some of the songs in this volume deserve to take rank with the best things of their kind in our literature. In an age of enfeebled poetic style, when Wordsworth, with more weighty apparatus, had as yet scarcely begun his reform of English versification, Blake, unaided by any contemporary influence, produced a work of fresh and living beauty; and if the *Songs of Innocence* established Blake's claim to the title of poet, the setting in which they were given to the world proved that he was also something more. For the full development of his artistic powers we have to wait till a later date, but here at least he exhibits a just and original understanding of the sources of decorative beauty. Each page of these poems is a study of design, full of invention, and often wrought with the utmost delicacy of workmanship. The artist retained to the end this feeling for decorative effect; but as time went on, he considerably enlarged the imaginative scope of his work, and decoration then became the condition rather than the aim of his labour.

Notwithstanding the distinct and precious qualities of this volume, it attracted but slight attention, a fact perhaps not very wonderful, when the system of publication is taken into account. Blake, however, proceeded with other work of the same kind. The same year he published *The Book of Thel*, more decidedly mystic in its poetry, but scarcely less beautiful as a piece of illumination; *The Marriage of Heaven and Hell* followed in 1790; and in 1793 there are added *The Gates of Paradise*, *The Vision of the Daughters of Albion*, and some other "Prophetic Books." It becomes abundantly clear on reaching this point in his career, that Blake's utterances cannot be judged by ordinary rules. The *Songs of Experience*, put forth in 1794 as a companion to the earlier *Songs of Innocence*, are for the most part intelligible and coherent, but in these intervening works of prophecy, as they were called by the author, we get the first public expression of that phase of his character and of his genius upon which a charge of insanity has been founded. The question whether Blake was or was not mad seems likely to remain in dispute, but there can be no doubt whatever that he was at different periods of his life under the influence of illusions for which there are no outward facts to account, and that much of what he wrote is so far wanting in the quality of sanity as to be without a logical coherence. On the other hand, it is equally clear that no madness imputed to Blake could equal that which would be involved in the rejection of his work on this ground. The greatness of Blake's mind is even better established than its frailty, and in considering the work that he has left we must remember that it is by the sublimity of his genius, and not by any mental defect, that he is most clearly distinguished from his fellows. With the publication of the *Songs of Experience* Blake's poetic career, so far at least as ordinary readers are concerned, may be said to close. A writer of prophecy he continued for many years, but the work by which he is best known in poetry are those earlier and simpler efforts, supplemented by a few pieces taken from various sources, some of which were of later production. The body of Blake's intelligible verse is now made accessible to the public, in Mr W. Rossetti's edition of his works, published in the Aldine series, and to this volume those readers may be referred who desire to know the foundation upon which the poet's fame has been built. But although Blake the poet ceases in a general sense at this date, Blake the artist is only just entering upon his career. In the *Songs of Innocence* and *Experience*, and even in some of the earlier *Books of Prophecy*, the two gifts worked together in perfect balance and harmony; but at this point the supremacy of the artistic faculty

asserts itself, and for the remainder of his life Blake was pre-eminently a designer and engraver. The labour of poetical composition continues, but the product passes beyond the range of general comprehension; while, with apparent inconsistency, the work of the artist gains steadily in strength and coherence, and never to the last loses its hold upon the understanding. It may almost be said without exaggeration that his earliest poetic work, *The Songs of Innocence*, and nearly his latest effort in design, the illustrations to *The Book of Job*, take rank among the sanest and most admirable products of his genius. Nor is the fact, astonishing enough at first sight, quite beyond a possible explanation. As Blake advanced in his poetic career, he was gradually hindered and finally overpowered by a tendency that was most serviceable to him in design. His inclination to substitute a symbol for a conception, to make an image do duty for an idea, became an insuperable obstacle to literary success. He endeavoured constantly to treat the intellectual material of verse as if it could be moulded into sensuous form, with the inevitable result that as the ideas to be expressed advanced in complexity and depth of meaning, his poetic gifts became gradually more inadequate to the task of interpretation. The earlier poems dealing with simpler themes, and put forward at a time when the bent of the artist's mind was not strictly determined, do not suffer from this difficulty; the symbolism then only enriches an idea of no intellectual intricacy; but when Blake began to concern himself with profounder problems the want of a more logical understanding of language made itself strikingly apparent. If his ways of thought and modes of workmanship had not been developed with an intensity almost morbid, he would probably have been able to distinguish and keep separate the double functions of art and literature. As it is, however, he remains as an extreme illustration of the ascendency of the artistic faculty. For this tendency to translate ideas into image, and to find for every thought, however simple or sublime, a precise and sensuous form, is of the essence of pure artistic invention. If this be accepted as the dominant bent of Blake's genius, it is not so wonderful that his work in art should have strengthened in proportion as his poetic powers waned; but whether the explanation satisfies all the requirements of the case or not, the fact remains, and cannot be overlooked by any student of Blake's career.

In 1796 Blake was actively employed in the work of illustration. Edwards, a bookseller of New Bond Street, projected a new edition of Young's *Night Thoughts*, and Blake was chosen to illustrate the work. It was to have been issued in parts, but for some reason not very clear the enterprise failed, and only a first part, including forty-three designs, was given to the world. These designs were engraved by Blake himself, and they are interesting not only for their own merit but for the peculiar system by which the illustration has been associated with the text. Quite recently it has been discovered that the artist had executed original designs in water colour for the whole series, and these drawings, 537 in number, form one of the most interesting records of Blake's genius. Mr Gilchrist, the painter's careful and sympathetic biographer, in commenting upon the engraved plates, regrets the absence of colour, "the use of which Blake so well understood, to relieve his simple design and give it significance," and an examination of the original water colour drawings fully supports the justice of his criticism. Soon after the publication of this work Blake was introduced by Flaxman to the poet Hayley, and in the year 1801 he accepted the suggestion of the latter, that he should take up his residence at Felpham in Sussex. The mild and amiable poet had planned to write a life of Cowper, and for the illustration of this and other works he sought Blake's help and companionship. The residence at Felpham continued for three years, partly pleasant and partly irksome to Blake, but apparently not very profitable to the progress of his art. One of the annoyances of his stay was a malicious prosecution for treason set on foot by a common soldier whom Blake had summarily ejected from his garden; but a more serious drawback was the increasing irritation which the painter seems to have experienced from association with Hayley. In 1804 Blake returned to London, to take up his residence in South Moulton Street, and as the fruit of his residence in Felpham, he published, in the manner already described, the prophetic books called the *Jerusalem, The Emanation of the Giant Albion*, and *Milton*. The first of these is a very notable performance in regard to artistic invention. Many of the designs stand out from the text in complete independence, and are now and then of the very finest quality.

In the years 1804–1805 Blake executed a series of designs in illustration of Blair's *Grave*, of much beauty and grandeur, though showing stronger traces of imitation of Italian art than any earlier production. These designs were purchased from the artist by an adventurous and unscrupulous publisher, Cromek, for the paltry sum of £21, and afterwards published in a series of engravings by Schiavonetti. Despite the ill treatment Blake received in the matter, and the other evils, including a quarrel with his friend Stothard as to priority of invention of a design illustrating the Canterbury Pilgrims, which his association with Cromek involved, the book gained for him a larger amount of popularity than he at any other time secured. Stothard's picture of the Canterbury Pilgrims was exhibited in 1807, and in 1809 Blake, in emulation of his rival's success, having himself painted in water colour a picture of the same subject, opened an exhibition, and drew up a *Descriptive Catalogue*, curious and interesting, and containing a very valuable criticism of Chaucer.

The remainder of the artist's life is not outwardly eventful. In 1813 he formed, through the introduction of George Cumberland of Bristol, a valuable friendship with Mr John Linnell and other rising water colour painters. Amongst the group Blake seems to have found special sympathy in the society of Varley, who, himself addicted to astrology, encouraged Blake to cultivate his gift of inspired vision; and it is probably to this influence that we are indebted for several curious drawings made from visions, especially the celebrated "ghost of a flea" and the very humorous portrait of the builder of the Pyramids. In 1821 Blake removed to Fountain Court, in the Strand, where he died 1827. The chief work of these last years was the splendid series of engraved designs in illustration of the book of Job. Here we find the highest imaginative qualities of Blake's art united to the technical means of expression which he best understood. Both the invention and the engraving are in all ways remarkable, and the series may fairly be cited in support of a very high estimate of his genius. None of his works are without the trace of that peculiar artistic instinct and power which seizes the pictorial element of ideas, simple or sublime, and translates them into the appropriate language of sense; but here the double faculty finds the happiest exercise. The grandeur of the theme is duly reflected in the simple and sublime images of the artist's design, and in the presence of these plates we are made to feel the power of the artist over the expressional resources of human form, as well as his sympathy with the imaginative significance of his subject.

A life of Blake, with selections from his works by Alexander Gilchrist, was published in 1863; in 1868 Mr Swinburne published a critical essay on his genius re-

markable for a full examination of the Prophetic Books, and still more recently Mr William Rossetti has published a memoir prefixed to an edition of the poems. (J. C. C.)

BLANC, Mont, the highest, and in other respects one of the most remarkable mountains in Europe, is situated in that division of the great Alpine system known as the Pennine Alps, in 45° 49′ 58″ N. lat. and 6° 51′ 54″ E. long. It rises almost in the shape of a pyramid to the height of 15,780 feet, and is visible at a distance of 130 miles to the west. The mass of the mountain is composed of granite, covered with strata of schists and limestones. To the N.E. lies the beautiful vale of Chamouni, and on the S.W. the Allée Blanche. Of the numerous glaciers that send their ice-streams down its sides the most remarkable is the Mer de Glace, which winds down its northern slope towards Chamouni, and gives birth to the River Arve. The ascent of Mont Blanc was first accomplished in 1786 by a guide named Jacques Balmat, who shortly afterwards led Dr Paccard, a local physician, to the summit, and thus gave him the honour of being the first person of scientific education to make known the possibility of the undertaking. De Saussure, the naturalist, ascended in the following year, and when the Italian naturalist Imperiale de Sant-Angelo made the ascent in 1840 he had been preceded by thirty-three known travellers. The whole journey to the top and back can now be accomplished in 50 or 60 hours; but in general the view can hardly be said to be worth the fatigue, the extreme height of the position, even when the outlook is unclouded, rendering the prospect indistinct. For authorities and maps, see Alps, vol. i. pp. 635–6.

BLANE, Sir Gilbert, a distinguished physician, was born at Blanefield in Aryshire, in 1749, and died in London in 1834. He was educated at Edinburgh University, and shortly after his removal to London became private physician to Lord Rodney, whom he accompanied to the West Indies. Through his skill and exertions the health of the seamen on board the fleet remained comparatively unaffected by the climate; and on his return home he embodied the results of his experience in a treatise *On the Diseases of Seamen*, 1783. He rose rapidly to fame, acquired an extensive practice, and in 1812 was appointed physician in ordinary to the Prince of Wales, with the rank of baronet. When at the head of the Navy Board of Health, an office he held for some years, he introduced many useful measures for securing the health of seamen during long voyages. Of his numerous works the most important is the *Elements of Medical Logic*, 1819.

BLAÑES, a city of the province of Gerona in Spain, at the mouth of the River Tordera, defended by a castle. The population, 5900 in number, are principally employed in the fisheries and navigation. Lace is manufactured by the women. Long. 2° 51′ E., lat. 41° 42′ N.

BLARNEY, a small village of Ireland, in the county of Cork, about 5 miles from that city, chiefly celebrated as giving name to a peculiar kind of eloquence, alleged to be characteristic of the natives of Ireland. The "Blarney Stone," the kissing of which is said to confer this faculty, is pointed out within the castle.

BLASPHEMY means literally defamation or evil speaking, but is more peculiarly restricted to an indignity offered to the Deity by words or writing. The common law of England treats blasphemy as an indictable offence. All blasphemies against God, as denying his being, or providence, all contumelious reproaches of Jesus Christ, all profane scoffing at the Holy Scriptures, or exposing any part thereof to contempt or ridicule, are punishable by the temporal courts with fine, imprisonment, and also infamous corporal punishment. The Act 1 Edw. VI. c. 1 (repealed 1 Mary, c. 2, and revived 1 Eliz. c. 1), enacts that persons reviling the sacrament of the Lord's supper, by contemptuous words or otherwise, shall suffer imprisonment. Persons denying the Trinity were deprived of the benefit of the Act of Toleration by 1 Will. III. c. 18. The 9 and 10 Will. III. c. 32, enacts that if any person, educated in or having made profession of the Christian religion, should by writing, preaching, teaching, or advised speaking, deny any one of the persons of the Holy Trinity to be God, or should assert or maintain that there are more gods than one, or should deny the Christian religion to be true, or the Holy Scriptures to be of divine authority, he should, upon the first offence, be rendered incapable of holding any office or place of trust, and for the second incapable of bringing any action, of being guardian or executor, or of taking a legacy or deed of gift, and should suffer three years' imprisonment without bail. It has been held that a person offending under the statute is also indictable at common law (Rex *v.* Carlisle, where Mr Justice Best remarks, "In the age of toleration, when that statute passed, neither churchmen nor sectarians wished to protect in their infidelity those who disbelieved the Holy Scriptures"). The 53 Geo. III. c. 160, excepts from these enactments "persons denying as therein mentioned respecting the Holy Trinity," but otherwise the common and statute law on the subject remains as stated. In the case of Rex *v.* Woolston (2 Geo. II.) the court declared that they would not suffer it to be debated whether to write against Christianity in *general* was not an offence punishable in the temporal courts at common law, but they did not intend to include disputes between learned men on *particular* controverted points. The law against blasphemy has not recently been in active operation. In 1841, Moxon was found guilty of the publication of a blasphemous libel (Shelley's *Queen Mab*), the prosecution having been instituted by Hetherington, who had previously been condemned to four months' imprisonment for a similar offence, and wished to test the law under which he was punished. In the case of Cowan *v.* Milbourn, in 1867, the defendant had broken his contract to let a lecture-room to the plaintiff, on discovering that the intended lectures were to maintain that "the character of Christ is defective, and his teaching misleading, and that the Bible is no more inspired than any other book," and the Court of Exchequer held that the publication of such doctrine was blasphemy, and the contract therefore illegal On that occasion the court reaffirmed the dictum of C. J. Hale, that Christianity is part of the laws of England. The Commissioners on Criminal Law (sixth report) remark, that "although the law forbids *all* denial of the being and providence of God or the Christian religion, it is only when irreligion assumes the form of an insult to God and man that the interference of the criminal law has taken place."

Profane cursing and swearing is made punishable by 19 Geo. II. c. 21, which directs the offender to be brought before a justice of the peace, and fined 5 shillings, 2 shillings, or 1 shilling, according as he is a gentleman, below the rank of gentleman, or a common labourer, soldier, &c.

By the law of Scotland, as it origionally stood, the punishment of blasphemy was death. By an Act passed in the first parliament of Charles II., whoever, "not being distracted in his wits," should curse God or any person of the blessed Trinity was punishable with death; and by a statute of King William's reign (1695, c. 11), any person reasoning against the being of God, or any person of the Trinity, or the authority of the Holy Scriptures, or the providence of God in the government of the world, was to be imprisoned for the first offence until he should give public satisfaction in sackcloth to the congregation, to be punished more severely for the second offence, and for the third doomed to death; but by 6 Geo. IV. c. 47, amended by 7 Will. IV. and 1 Vict. c. 5, blasphemy was made punishable by fine or imprisonment or both. (E. R.)

BLASTING is the process by which portions of rock, or other hard substances, are disintegrated by means of an explosive agent, such as gunpowder. It is largely resorted to in quarrying, tunnelling, and mining operations.

Of late years there has been rapid advance in the art, through the discovery of new explosives, through improvements in appliances for firing, &c.; so that the older method of blasting has, in many instances, given place to a more complex system, with which much better results are obtained. The simpler process may be described thus. When a blast is to be made, a hole to receive powder is first bored in the rock; such holes vary in diameter from ½ inch to 2½ inches, in depth from a few inches to many feet, and in direction from the vertical to the horizontal. The borer, or jumper, with which the hole is made is a steel pointed drill; it is struck by a hammer, and is turned partly round after each blow, to make the hole cylindrical. One man may do all this alone, but generally, in the case of larger holes, a man, in sitting posture, directs the jumper, supplies the hole with water, and clears out the powdered stone at intervals with a scraper, while another man, or two, or three, are engaged in striking. A small rope of straw or hemp is twisted round the jumper at the orifice of the hole to prevent squirting up of the water. In the case of soft rock a loaded drill is sometimes used, which acts merely by its own weight. On the other hand, in substances like pyrites, or compact magnetic iron ore, which cannot be penetrated with steel drills, holes for blasting may be made by the gradual action of an acid (commonly muriatic) admitted through a vertical glass tube. When a sufficient depth is reached, the whole is cleaned and dried, and a charge of powder put in. A small taper rod of copper, the needle or nail, is inserted so as to reach to the bottom of the charge; then the rest of the hole is filled up with some such material as dry sand or tough clay, which forms the "tamping" or wadding, and which is firmly rammed down in small quantities successively by means of the tamping bar, a copper-faced punch of such thickness that it nearly fills the hole, and having a groove in it to receive the nail. This operation requires great care, because of the danger of eliciting sparks through collision. The hole being now fully charged, the nail is withdrawn, leaving a small vent hole, into which is then introduced an oaten straw filled with powder (or a series of such). To this is attached a slow match of paper steeped in saltpetre. The match is touched with fire; the alarm is given to retire to a safe distance; and presently the explosion takes place, the rock opening with a sharp report, and fragments of stones being often shot into the air in all directions. An improvement on this method of firing consists in the employment of Bickford's patent fuse, which may be described as a perforated rope or hose containing an inflammable composition. A suitable length of fuse is placed in contact with the charge before tamping, and carried up to the mouth of the hole. On being lighted it burns at the rate of 2 to 3 feet per minute, giving the miners an opportunity to escape before explosion. A water-tight form of the fuse is often used in submarine blasting,—the shot or charge being then made up in cartridge form.

Blasting, however, is often done on a much larger scale than that just indicated. As an example of the large blasts, or "mines," where great blocks of rock have to be removed at once, we might take some of the operations carried on at the Holyhead quarries a number of years ago for the harbour works. An entrance gallery, 5 feet 6 inches by 3 feet 6 inches was first driven from the face of the rock (hard quartzose schist), an extent of 34 feet, where a shaft, 3 feet 6 inches by 3 feet 6 inches, was sunk to a depth of 14 feet. From this, level galleries were driven some distance right and left, with four short headings, at intervals, returning towards the face of the rock and terminating in chambers for the charges. The four charges, amounting in all to 12,000 ℔ of powder, were enclosed in canvas bags coated with tar. They were calculated at the rate of 1 ℔ of powder to 3 tons of rock. For tamping a stiff red clay was used; it was well rammed up close to the bags of powder (leaving a small air space round these), and continued to the mouth of the gallery. The charges were fired simultaneously by means of platinum wire heated by a Grove's battery. The total quantity of rock removed was about 40,000 tons; it was separated into various sized blocks. Similarly, the Rounddown Cliff at Dover was overthrown in 1843 for railway purposes by 18,500 ℔ of powder, in three separate charges, fired simultaneously from a Voltaic battery; a saving of £7000 was thus effected by the South-Eastern Railway Company.

In reviewing recent developments of the art of blasting, the application of machinery in the boring of rocks naturally claims some attention. A good rock-boring machine, at least where used in connection with simultaneous firing by electricity, ensures considerable economy in time and labour over the old method of hand-boring. Of such machines, in which the jumper is repeatedly driven against the rock by compressed air or steam, being also made to rotate slightly at each blow, there are several varieties; the Burleigh rock drill is one of the best. It was used in the Hoosac tunnel in Massachusetts from 1869; and the last 5220 yards were completed with only eight of these machines. The rock was gneiss alternating with quartz. With hand-boring, the progress per minute was about 16 yards; with the Burleigh drill it was 48 yards, and the work was about one-third cheaper. According to *Engineering*, the cost of the Mont Cenis tunnel was £195 per linear yard; that of the Hoosac tunnel, notwithstanding much harder rock, only £180. In the recent large blastings at Hellgate, New York, the Burleigh machines also established their superiority, and came to be used exclusively. Among other boring-machines may be mentioned the "Diamond" drill, and the systems of Law, Ingersoll, M'Kean, Bergstroem, Sachs, Doering.

The general properties of ordinary blasting-powder are well known; it requires to be kept dry, and when dry, a spark of fire will cause it to explode. Various efforts have of late years been made towards the employment of more powerful explosive agents for blasting purposes. The violent oxidizing power of chlorate of potash marked it out as available for explosive mixtures; and sundry preparations containing this substance have been made (some of them highly dangerous). *Horsley's Blasting-Powder*, consisting of powdered nut galls and chlorate, may be taken as a type of these mixtures, and as the safest of them. It is both more violent and more rapid in explosion than ordinary blasting-powder, and does not give off any smoke or unpleasant smell when it explodes. It must be kept dry, and it is liable to explode through friction; the expensiveness of its ingredients is also a drawback. *Gun-cotton* was discovered by Schönbein in 1846, but owing to disastrous accidents occurring in the three years which followed, it was abandoned in this country and in France for sixteen years. Through the researches, meanwhile, of an Austrian, Baron von Lenk, it again came into notice in 1864, and a Government committee investigated the merits of the gun-cotton twist or rope made according to the Austrian system. For blasting hard rock its general superiority in effect to powder was recognized; and the absence of smoke, where the resistance opposed to the gun-cotton was sufficient to develop its full explosive force, was specially remarked upon. The want of rigidity of the material was objectionable; and several accidents

occurred, through violent friction of the twist, when miners had attempted to drive home a jammed charge. A considerable gain was secured by the invention of *compressed gun-cotton* by Professor Abel in 1868. In this form the explosive occupied less than half the space of the rope charges, and the smooth, hard exterior of the cylindrical charges rendered the operation of loading comparatively easy. The compressed charges, moreover, did not burn with the explosive violence of spun gun-cotton even when confined in the ordinary packing-cases. Among further improvements may be noted the cheapening of the material by use of cotton waste, instead of the long staple cotton of high quality that was used in the Austrian manufacture. In 1868 Mr E. O. Brown discovered that (like nitroglycerine)[1] compressed gun-cotton was susceptible of violent explosion through the agency of a detonation, as well as in the ordinary way. This was important, especially for submarine operations and works of demolition; for the strong confinement which was always necessary in the other case could be dispensed with; indeed, with some waste of power, the substance might be exploded completely unconfined. Gun-cotton is not affected in its explosiveness by cold; and it can be kept any length of time without deterioration in the damp and perfectly unignitable state. The formula that has been assigned for the most explosive gun-cotton is $C_6H_7N_3O_{11}$.

In 1864 Mr Nobel's researches called attention to the application of *nitroglycerine* (discovered by Sobrero in 1846) as an explosive agent. He first showed that the effect of gunpowder was considerably increased through impregnation with it; and later, that the liquid itself, which burns slowly in the air on application of a flame with a common fuse, could be exploded by an initiative detonation,—confinement by tamping being then unnecessary. In its pure state it was soon proved to be the most powerful explosive yet known; its destructive force is about ten times that of gunpowder. Its liquid form, high specific gravity, and insolubility in water, are valuable properties in some cases, as in blasting under water or in wet holes. It freezes at a comparatively high temperature (40° Fahr.); but the opinion, formed from several grave accidents, that it was more susceptible of detonation in the frozen than in the liquid state, has been shown to be contrary to fact. When frozen it is more liable to recklessly rough usage. The liquid state of nitroglycerine, on the other hand, constitutes a very serious defect, owing to its tendency to leak from vessels in which it is carried, or from the blast-hole, through fissures in the rock,—resulting in unexpected explosions, it may be, through some slight concussion. Mr Nobel's ingenious device for rendering nitroglycerine temporarily inexplosive, by dissolving it, viz., in wood spirit, is only partially successful. Nitroglycerine has been extensively used in various mining districts, especially in California. After some terrible accidents, which occurred in 1866–7, its use in England was placed under severe restrictions.

Impressed with the serious disadvantages of this explosive, Mr Nobel was led to the important observation that its readiness to explode by detonation is not diminished, but rather favoured, by mixture with solid substances, in themselves quite inert; and the dilution did not materially detract from the great superiority of nitroglycerine over gunpowder. In 1867 he brought before the public the substance appropriately called *dynamite*, which is one of the safest, most powerful, and most convenient explosives for industrial purposes. It consisted of seventy-five parts of nitroglycerine held absorbed by twenty-five parts of a porous, infusorial, silicious earth, known in Germany as "Kieselguhr." Other absorbents have been employed (precipitated kaolin, tripoli, precipitated alumina, sugar, &c.), but none of them are equal to kieselguhr in power of retaining oil. Dynamite is furnished to the trade in the form of small cylindrical cartridges, in which the material, consolidated by pressure, is enclosed in a single wrapping of parchment paper. It requires no tamping, and can be exploded by detonation under water. It is slow to catch fire, but burns rather fiercely when fired; and if the quantities are large, or under confinement, an explosion may finally ensue. The trade in it has developed rapidly; thus, while only 11 tons of it were sold in 1867, the quantity rose to 3120 tons in 1874.

In the preparation known as *lithofracteur*, which came into notice during the Franco-German War, nitroglycerine is used in considerably smaller proportions than in dynamite; and the kieselguhr of the latter is partly replaced by materials forming of themselves a feebly explosive mixture. Its properties are very similar to those of dynamite, but it is less powerful.

The less known ammonia powder, invented by Ohlson and Norbin, is much stronger than lithofracteur, and even surpasses dynamite. Its only drawback is the hygroscopic nature of its chief ingredient, which is nitrate of ammonium; but otherwise it is a very superior blasting agent. Numerous other explosives have been tried in blasting, but those we have named are amongst the most important.

In a recent paper to the Society of Arts, Mr Nobel has discussed the relative power of several blasting agents. He finds that when their ballistic power is compared bulk for bulk, the substances experimented with rank as follows:—Nitroglycerine, 100; ammonia powder, 80; dynamite (No. 1), 74; lithofracteur, 53; gun-cotton, 45; Curtis and Harvey's blasting-powder (fired by detonator), 17·5. While these figures show the great superiority of nitroglycerine, there are practical circumstances which bring it and dynamite nearly on an equality. Thus, to get the full benefit of a blast there should be no air-space round the charge. Now, from the danger (as we have seen) of nitroglycerine leaking through imperceptible fissures in a rock, rigid cartridges are required for it, and these always involve a considerable air chamber, whereas dynamite, being highly plastic, can be easily compressed so as to exclude all empty space. The cartridges of compressed gun-cotton are also liable, of course, to the objection just noticed.

Where rapid destruction is to be accomplished there is a saving of labour, of tools, and of time by use of the new explosive agents (such as dynamite or gun-cotton). Their shattering and splitting effect in hard rock is much greater; but in quarrying, the rock is generally not thrown out by them to the same extent. Where a moderate cleaving or splitting effect is desired, with as little local action as possible, gunpowder is best, as in raising large blocks of slate; also where great displacing action is required. In submarine blasting of soft rocks the violent explosives disintegrate the rock into a plastic mass within a limited area, but do not shatter or rend it to any great distance.

As regards comparative safety, there is no doubt that modern explosives offer a relative immunity from the danger arising from fire, to which gunpowder is subject. Neither dynamite nor gun-cotton can be fired by a spark, and if accidentally fired by a flame, they allow reasonable chances of escape. On the other hand, accidents have often happened in the thawing of nitroglycerine preparations when frozen,—a process that requires great care, and for which suitable warming-pans are provided. But miners are slow to understand that a cartridge which firing does not set off cannot be slowly heated with the same impunity; hence they will roast the preparations near a

[1] It was found, in the course of these inquiries, that all explosive compounds, even including gunpowder, are susceptible of explosion through a detonation, though the nature and force of the detonation vary considerably with different explosive substances.

fire, or on hot cinders, or in other ways really dangerous. Gun-cotton and dynamite prove much safer than nitroglycerine as regards exploding through concussion. There is not, however (Mr Nobel thinks), that amount of difference between the sensitiveness of nitroglycerine and dynamite which the latter substance generally receives credit for. The main danger of nitroglycerine arose from the sensitiveness to concussion which it acquired through contact with a hard, metallic, strongly vibrating substance, such as the tin canisters in which it was contained. The main safety of dynamite is derived from the absence of any hard vibrating material in immediate contact with the nitroglycerine it contains.

As regards danger from concussion in manufacture and transit, gun-cotton ranks first; but in the hands of miners, the case is reversed, through the rough usage of gun-cotton charges, where, *e.g.*, they are found too large for a bore-hole, for gun-cotton is well known to explode with a blow. The danger most dreaded in modern explosives is from their supposed liability to chemical decomposition productive of heat, which sometimes leads to ignition and explosion. This decomposition is generally due to the presence of acid (chiefly nitric and hyponitric), which every nitrated compound has a strong tendency to retain. From the ease with which the acid can be washed out from nitroglycerine, both it and dynamite show much greater chemical stability than gun-cotton. Most cases of spontaneous combustion of the latter have probably arisen either from imperfect washing, or from drying at too high a temperature (by which hyponitric acid is set free).

Complaints have often been made of the poisonous fumes given off by the new explosives. Where this occurs, it is probably due to an injudicious use of the substance, resulting in imperfect explosion. If a dynamite cartridge partly burns instead of exploding, the temperature is much lower, and fumes of hyponitric acid are given off, which could not escape decomposition at the higher temperature of perfect explosion. The general mistake consists in not securing carefully the detonator cap to the fuse, and especially the fuse to the cartridge.

Blasting by Electricity.—It is known that electricity has a thermal effect on wire through which it passes; and the amount of heat produced in any part of the circuit is proportional to the resistance in that part. Thus a piece of wire of small section and conductivity may be made incandescent by a current. On this principal platinum is sometimes employed to fire blasting charges. In making a fuse of this sort, two insulated copper wires are twisted together for a length of about 6 inches, leaving the extremities free for about half an inch, and separated the same distance. A fine platinum (or iron) wire is stretched across this interval, metallic contact being established with the copper. The other ends of the fuse are connected with a battery. Platinum fuses are not much to be relied on for simultaneous blasting of several charges by one battery; for some of the fuses may take a little more time to reach the exploding temperature than others, and thus, as soon as one explodes, the connection between the others and the battery is broken. The batteries to be used with them are such as generate electricity of great quantity. The Bunsen and Leclanché batteries, in some of their varieties, are well suited for this. Twelve cells of Highton's battery will melt a piece of platinum wire over an inch long.

There is, however, another class of fuses, offering certain advantages over those just referred to, in which the spark produced by electricity of tension is the means used to effect the explosion. It might naturally be thought that an electric spark must inevitably cause explosion in a mass of powder or like substance through which it is made to pass; but this is not the case. The heating power of the spark is often insufficient for explosion. The duration of an induction spark is about the *millionth* of a second; whereas, to ignite powder, it is necessary that a spark should exist for at least the *three hundredth* part of a second. By interposing, however, a suitable priming composition in the interval which the spark is to cross, and in contact with the charge, explosion may be thus effected. In preparing such a composition, the properties of the ingredients as regards conductivity, inflammability, and explosiveness have to be nicely adjusted, according to the degree of tension of the electricity employed. The composition selected by Professor Abel for his fuses is an intimate mixture of subsulphide of copper, subphosphide of copper, and chlorate of potassium. It is a mixture which conducts, but conducts with difficulty, and the fuses made with it are very effective. There are several other varieties *e.g.*, Ebner's fuse, where the priming consists of a mixture of sulphuret of antimony, chlorate of potash, and graphite.[1]

For generating electricity of tension with the Voltaic battery, Leclanché's battery is, again, one of the most suitable. The elements of this battery consist of a rod of carbon placed in a porous cell and tightly packed round with a mixture of peroxide of manganese and coke; the porous cell is placed in a vessel containing a plate of zinc, which forms the electro-positive element, and a solution of sal-ammoniac is used as the exciting liquid. There are some forms of battery for the same purpose so arranged that the contact of the elements with the liquid takes place only at the time of firing; such are those of Wollaston, Ruhmkorff, and Trouvé.

Frictional electricity is the kind generally adopted by military authorities in firing charges,—the machines for generating it being easily made, simple, portable, and powerful. Bornhardt's frictional machine has found extensive use in Austria in ordinary blasting operations. It is contained in a small metallic case, and consists of a disc of ebonite, which can be rotated between two cushions, charging a small Leyden jar placed near it. On pressing a little button from the outside, connection is made between the two coatings of the jar in such a way that the charge is sent through two wires by which the box is connected with the fuse, or fuses, at a distance. Some absorbent of moisture is kept within the box, and it is necessary to see that the machine be kept as warm and dry as possible.

Experiments were made by Messrs Wheatstone and Abel, a number of years ago, with Armstrong's hydroelectric machine, as a source of electricity for exploding charges of powder. They state that in very extensive mining operations, where a great many charges have to be fired simultaneously, and provided all the necessary appliances for success are at hand, the machine could be used very effectively. It is a powerful source of electricity of high tension. There are serious objections, however, to its general use.

Electro-magnetic induction currents (such as are developed in Ruhmkorff's coil) were first applied, and successfully, by Colonel Verdu, a Spanish officer, in 1853. The induction discharge, unlike that of a Leyden battery, is much enfeebled by successive solutions of continuity, so that not more than four mines in a single circuit could certainly be exploded on this system. But M. Savare made an improvement by interposing the fuses in branches of the principal circuit. The mine nearest the apparatus explodes first; and, owing to the abrupt separation of the wires, the current can no longer pass through this branch; thus the electric action is augmented in the other branches, and in a similar manner the explosions necessarily take

[1] In one form of fuse employed with dynamite, there is connected with the priming just mentioned some mercuric fulminate and loose gun-cotton.

place in them, and that with a rapidity almost instantaneous. This is also a more efficient plan than that of employing a rheotome for changing the direction of the current, so as to bring wires connected with one or more charges successively into the circuit. The Ruhmkorff coil is, however, objectionable for its delicacy and the maintenance of batteries in connection with it. In experiments made by Messrs Wheatstone and Abel, a powerful magneto-electric machine was found very limited in its power of igniting several charges arranged in succession in one circuit (it only ignited three at most, with certainty); but on M. Savare's plan of arranging the charges in divided circuits, the simultaneous ignition of twenty-five charges was repeatedly effected; on several occasions as many as forty. By this plan each charge was connected with a separate branch attached to the main line, and their connection with earth established by means of uncovered copper wire wound round an iron stake driven in the ground. Another form of instrument, devised by Wheatstone, consists of six small magnets, to the poles of which are fixed soft iron bars surrounded by coils of insulated wire; the coils of all the magnets are united together, so as to form, with the external conducting wire and the earth, a single circuit. An axis carries six soft iron armatures, in succession, before each of the coils. With this apparatus twenty-five charges were frequently fired in divided circuit, so rapidly that the effect on the ear was as of one explosion, only of slightly longer duration than when the large magnet was employed. The Markus apparatus, largely used in Germany, is on the same principle.

Siemens's dynamo-electric machine, in which electro-magnets are employed, is a very useful machine for simultaneous firing. It is found that the residual magnetism left in the coils of electro-magnets, after a current from even a single Voltaic cell has been once sent through them, is always sufficient to have the necessary inductive action on the armature. This inductive action, though very weak at first, generates slight alternating currents in the armature, which are by means of a commutator caused to flow always in one direction through the coils of the electro-magnet, thus increasing the magnetism in the core, which, in its turn, increases the inductive action, causing stronger and stronger currents to be generated in the armature. This action and reaction goes on till the limit of magnetic capacity of the core is reached, and if the coil of the armature be then suddenly connected with the line leading to a fuse, a very powerful current is transmitted. In Breguet's exploder (in which a bar of soft iron is suddenly separated from the armature of a magnet bearing two induction coils) a special arrangement gives rise to an extra-current, and considerably increases the intensity of the current. M. Breguet has lately utilized in this apparatus the new and powerful laminated magnets constructed by M. Jamin. Gramme's machines are also effective in exploding charges, but their volume and high price are against a large use of them industrially.

For more detailed information on the recent developments of blasting, reference may be made to Spon's *Dictionary of Engineering*, art. "Boring and Blasting;" *Professional Papers of the Corps of Royal Engineers*, vols. vii., x., xxii.; *Transactions of the Society of Engineers*, 1869 and 1871; *Proceedings of South Wales Institute of Mining Engineers*, vol. viii., No. 5, vol. ix., Nos. 1 and 2; Dingler's *Polytechnisches Journal*, Oct. 1, 1874; *Annales de Chimie et de Physique*, May 1875; *Journal of the Society of Arts*, May 28, 1875. BLEACHING

BLEACHING is the process of whitening or depriving objects of colour, an operation incessantly in activity in nature by the influence of light, air, and moisture. The art of bleaching, of which we have here to treat, consists in inducing the rapid operation of whitening agencies, and as an industry it is mostly directed to cotton, linen, silk, wool, and other textile fibres, but it is also applied to the whitening of paper-pulp, bees'-wax, and some oils and other substances. The term bleaching is derived from the Anglo-Saxon *blæcan*, to bleach, or to fade, from which also comes the cognate German word *bleichen*, to whiten or render pale. Bleachers, down to the end of last century, were known in England as "whitsters," a name obviously derived from the nature of their calling.

The operation of bleaching must from its very nature be of the same antiquity as the work of washing textures of linen, cotton, or other vegetable fibres. Clothing repeatedly washed, and exposed in the open air to dry, gradually assumes a whiter and whiter hue, and our ancestors cannot have failed to notice and take advantage of this fact. Scarcely anything is known with certainty of the art of bleaching as practised by the nations of antiquity. Egypt in early ages was the great centre of textile manufactures, and her white and coloured linens were in high repute among contemporary nations. As a uniformly well-bleached basis is necessary for the production of a satisfactory dye on cloth, it may be assumed that the Egyptians were fairly proficient in bleaching, and that still more so were the Phœnicians with their brilliant and famous purple dyes. We learn, from Pliny, that different plants, and likewise the ashes of plants, which no doubt contained alkali, were employed as detergents. He mentions particularly the *Struthium* as much used for bleaching in Greece, a plant which has been identified by some with *Gypsophila Struthium*. But as it does not appear from Sibthorp's *Flora Græca*, published by Sir James Smith, that this species is a native of Greece, Dr Sibthorp's conjecture that the *Struthium* of the ancients was the *Saponaria officinalis*, a plant common in Greece, is certainly more probable.

In modern times, down to the middle of the 18th century, the Dutch possessed almost a monopoly of the bleaching trade, although we find mention of bleach-works at Southwark near London as early as the middle of the 17th century. It was customary to send all the brown linen, then largely manufactured in Scotland, to Holland to be bleached. It was sent away in the month of March, and not returned till the end of October, being thus out of the hands of the merchant more than half a year.

The Dutch mode of bleaching, which was mostly conducted in the neighbourhood of Haarlem, was to steep the linen first in a waste lye, and then for about a week in a potash lye poured over it boiling hot. The cloth being taken out of this lye, and washed, was next put into wooden vessels containing butter-milk, in which it lay under a pressure for five or six days. After this it was spread upon the grass, and kept wet for several months, exposed to the sunshine of summer.

In 1728 James Adair from Belfast proposed to the Scotch Board of Manufactures to establish a bleachfield in Galloway; this proposal the board approved of, and in the same year resolved to devote £2000 as premiums for the establishment of bleachfields throughout the country. In 1732 a method of bleaching with kelp, introduced by R. Holden, also from Ireland, was submitted to the board; and with their assistance Holden established a bleachfield for prosecuting his process at Pitkerro, near Dundee.

The bleaching process, as at that time performed, was very tedious, occupying a complete summer. It consisted in steeping the cloth in alkaline lyes for several days, washing it clean, and spreading it upon the grass for some weeks. The steeping in alkaline lyes, called *bucking*, and the bleaching on the grass, called *crofting*, were repeated alternately for five or six times. The cloth was then steeped for some days in sour milk, washed clean, and crofted. These processes were repeated, diminishing every time the strength of the alkaline lye, till the linen had acquired the requisite whiteness.

For the first improvement in this tedious process, which was faithfully copied from the Dutch bleachfields, manufacturers were indebted to Dr Francis Home of Edinburgh, to whom the Board of Trustees paid £100 for his experiments in bleaching. He proposed to substitute water acidulated with sulphuric acid for the sour milk previously employed, a suggestion made in consequence of the new mode of preparing sulphuric acid, contrived some time before by Dr Roebuck, which reduced the price of that acid to less than one-third of what it had formerly been. When this change was first adopted by the bleachers, there was the same outcry against its corrosive effects as arose when chlorine was substituted for crofting. A great advantage was found to result from the use of sulphuric acid, which was that a souring with sulphuric acid required at the longest only twenty-four hours, and often not more than twelve; whereas, when sour milk was employed, six weeks, or even two months, were requisite, according to the state of the weather. In consequence of this improvement, the process of bleaching was shortened from eight months to four, which enabled the merchant to dispose of his goods so much the sooner, and consequently to trade with less capital.

No further modification of consequence was introduced in the art till the year 1787, when a most important change was initiated by the use of chlorine, an element which had been discovered by Scheele in Sweden about thirteen years before. Berthollet repeated the experiments of Scheele in 1785, and by the prosecution of further investigations he added considerably to the facts already known. He showed that this substance (called by Scheele *dephlogisticated muriatic acid*) is a gas soluble in water, to which it gives a yellowish green colour, an astringent taste, and the peculiar smell by which the body is distinguished.

The property which this gas possesses of destroying vegetable colours, led Berthollet to suspect that it might be introduced with advantage into the art of bleaching, and that it would enable practical bleachers greatly to shorten their processes. In a paper on dephlogisticated muriatic acid, read before the Academy of Sciences at Paris in April 1785, and published in the *Journal de Physique* for May of the same year (vol. xxvi. p. 325), he mentions that he had tried the effect of the gas in bleaching cloth, and found that it answered perfectly. This idea is still further developed in a paper on the same substance, published in the *Journal de Physique* for 1786. In 1786 he exhibited the experiment to Mr James Watt, who, immediately upon his return to England, commenced a practical examination of the subject, and was accordingly the person who first introduced the new method of bleaching into Great Britain. We find from Mr Watt's own testimony that chlorine was practically employed in the bleachfield of his father-in-law, Mr Macgregor, in the neighbourhood of Glasgow in March 1787. Shortly thereafter the method was introduced at Aberdeen by Messrs Gordon, Barron, and Co., on information received from M. de Saussure through Professor Copland of Aberdeen. Mr Thomas Henry of Manchester was the first to bleach with chlorine in the Lancashire district, and to his independent investigations several of the early improvements in the application of the material were due.

No very great amount of success, however, attended the efforts to utilize chlorine in bleaching operations till the subject was taken up by Mr Tennant of Glasgow. He, after a great deal of most laborious and acute investigation, hit upon a method of making a saturated liquid of chloride of lime, which was found to answer perfectly all the purposes of the bleacher. This was certainly a most important improvement, without which, the prodigious extent of business carried on by some bleachers could not possibly have been transacted. Such was the acceleration of processes effected by the new method that, it is stated, a bleacher in Lancashire received 1400 pieces of gray muslin on a Tuesday, which on the Thursday immediately following were returned bleached to the manufacturers, at the distance of sixteen miles, and were packed up and sent off on that very day to a foreign market.

In the year 1798 Mr Tennant took out a patent for his new invention, and offered the use of it to practical bleachers, for a fair and reasonable portion of the savings made by its substitution for potash, then in general use. Many of the bleachers, however, used it without paying him, and a combination was formed to resist the right of the patentee. In December 1802, an action for damages was brought against Messrs Slater and Varley, nominally the defendants, but who, in fact, were backed and supported by a combination of almost all the bleachers in Lancashire. In consequence of this action, the patent right was set aside by the verdict of a jury and the decision of Lord Ellenborough, who used very strong language against the patentee. The grounds of this decision were, that the patent included a mode of *bucking* with quicklime and water, which was not a new invention. It was decided that, because one part of the patent was not new, therefore the whole must be set aside. Lime was indeed used previous to the patent of Mr Tennant; but it was employed in a quite different manner from his, and he would have allowed the bleachers to continue their peculiar method without any objection, because it would have been productive of no injury to his emolument.

In consequence of this decision the use of liquid chloride of lime in bleaching was thrown open to all, and speedily came to be universally employed by the bleachers in Britain. Mr Tennant, thus deprived of the fruits of several years of anxious and laborious investigation, advanced a step farther, to what may be considered as the completion of the new method. This consisted in impregnating quicklime in a dry state with chlorine, an idea originally suggested by Mr Charles M'Intosh of Cross-Basket, then a partner with Messrs Tennant and Knox. A patent for this was taken out on the 13th of April 1799, and he began his manufacture of solid chloride of lime at first upon a small scale, which has ever since been gradually extending, and the manufactory is now the largest of the kind in Great Britain.

The various processes for the preparation of the so-called chloride of lime, or bleaching-powder, as conducted at the present day, and its other applications in arts, will be found described under the head of CHLORINE.

BLEACHING OF COTTON.

Of the two great staples, cotton and linen, to the whitening of which the art of the bleacher is directed, cotton is the more easily and expeditiously bleached. The basis of all vegetable fibres is cellulose or ligneous tissue, a pure white substance, and it is to obtain this body in a state of purity, free from the resinous matter naturally associated with it as well as from adventitious impurities

imparted in the process of spinning and weaving, that is the object of bleaching. The operations, although apparently complex and numerous, are essentially simple, though frequently repeated, and the greatest variety of detail is connected with the finishing of cloth, which is in reality a separate industry, frequently conducted in distinct establishments under the name of calendering and finishing works. Bleaching proper resolves itself into washing with suitable detergents, and subjecting the washed material to the influence of chlorine, whereby the colouring matter either belonging to the fibre or imparted to it is oxidized and discharged.

The general arrangements of a bleach-house will be made plain from the ground-plan (fig. 1). The various pieces

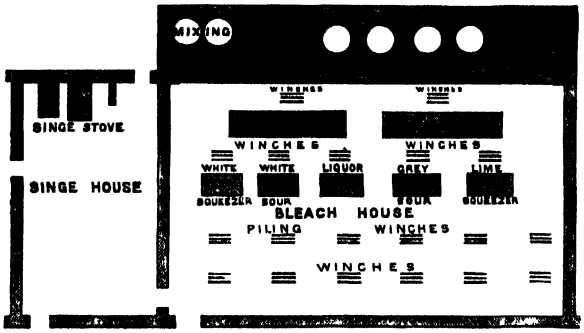

FIG. 1.—Ground-Plan of Bleach-House

of apparatus, the positions of which are there indicated, will be described in connection with the sequence of operations through which the cloth passes in the process of bleaching. In the best arranged works, it should be mentioned, where power is required to work any machine, it is generally supplied by a separate engine attached to the machine itself, instead of by gearing carried from one engine for all the machinery. For this plan, as well as for the greater portion of the illustrations which follow, we are indebted to Mr William Mather, of the eminent firm of Mather and Platt, Salford, to whom we are also under obligation for much valuable practical information. We have also to express our indebtedness to Mr Alexander Crum of Thornliebank, for the fullest access to the important works of his firm, and for the cordial assistance afforded by the managers of its various departments.

The sequence of operations in the bleaching and finishing of calico has undergone no change in its general details since the bleaching-powder process was first introduced; but the mechanical arrangements by which the operations are conducted have been the subject of frequent improvements. The ingenuity of engineers and bleachers has been chiefly directed towards the decreasing of manual labour, economy of fuel and materials, and the rapid completion of the various processes. The application of factory legislation to bleach-works by the Bleaching and Dyeing Works Act of 1860, by imposing a necessity for regular and stated hours of work, still further stimulated the production of apparatus and arrangements for prompt and certain completion of the various operations. Consequently a great part of the old machinery and arrangements of a bleach-house have now disappeared, and the processes are carried on in a continuous series of operations by machinery and appliances to a large extent self-acting. Formerly each piece of goods was separately treated and carried by hand or on barrows from one stage to the next; now the pieces are sewn end to end, as many as 1000 pieces, measuring perhaps 20 miles, being operated on in one stretch.

As various pieces of old machinery are yet in use for certain kinds of work, it has been considered desirable to give descriptions and figures of some of them, and these, at the same time, will serve the further purpose of indicating the nature of the mechanical improvements which have been carried out, in recent years, in bleaching establishments. The important and frequently repeated operation of washing was formerly conducted either at the wash-stocks or washing-mill or in the dash-wheel. The wash-stocks, which are yet in use in many large works, especially where linen is the bleacher's staple, consists of a trough or box for holding the goods to be washed, through which a constant stream of water is passing. A pair or more of heavy hammer-headed wooden beams, hung by long shafts, and playing into the trough, are alternately tilted against the cloth, causing the water by their momentum to work through and squirt out of the mass. This process of washing is rather tedious, occupying on an average about half an hour, and requiring besides a great amount of manual labour. The dash-wheel (fig. 2) is a cylindrical box revolving on its axis. It has four divisions, as shown by the dotted lines, and an opening into each division. A number of pieces are put into each, abundance of water is admitted behind, and the knocking of the pieces as they alternately dash from one side of the division to the other during the revolution of the wheel effects the washing. The process lasts from four to six minutes. The dash-wheel is used to the present day in the bleaching of curtain materials and fine muslins. In nothing have greater improvements been effected than in the arrangement of the kiers or vessels in which the cloth is boiled or "bowked." An old form of kier is seen in fig. 3. It consisted of a cylindrical vessel AA, 9 feet wide, of wood or iron, having a false bottom BB, on which the goods were placed, about 6 inches from the real one. A small pipe E, in the centre of a wider one CC, conveyed the steam from the steam - boiler. When the liquid boiled at the bottom, where the steam issued, the steam forced its way up the pipe CC, carrying with it a quantity of the lye, which was thrown back by the small cover D, spreading itself over the surface of the goods, and filtering through them into the space below the false bottom, where it was again heated by the steam, reascended the pipe CC, and so on in constant succession, till the boiling was completed. FF is a wooden cover which prevented the cooling of the materials below a boiling heat.

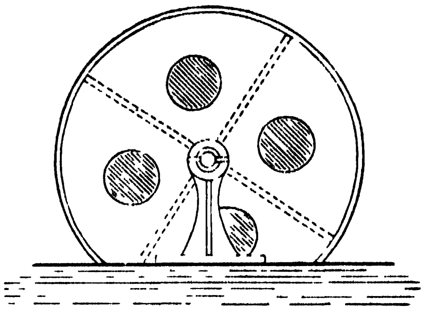

FIG. 2.—Section of a Dash-Wheel

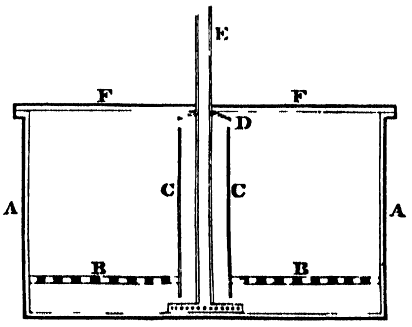

FIG. 3.—Section of Kier (old form).

The bleaching of common calico is divided into two branches—1st, print bleaching, in the case of which the goods are bleached as a preliminary to the process of calico printing; and 2d, white bleaching, which applies to goods to be finished white or unprinted. The processes differ in some of their details, as in white bleaching it is only neces-

sary to satisfy the eye, whereas in print bleaching the material must be rendered chemically pure, otherwise the colours in the subsequent printing process would be dull and blotchy. The print bleaching must therefore be more thoroughly done than the other; but as the processes are generally the same, it will be sufficient to indicate the points of difference in the various stages through which the material in both cases passes. A process preliminary to bleaching is

Singeing.—Gray calico as received from the looms is generally in lengths of 37½ and 50 yards. A large number of these, sometimes as many as 1000, measuring more than 20 miles in length, are sewn into a continuous web. At the extremities of each owner's lengths, the name of the firm, or some distinguishing mark, is either stamped on in tar, or marked by means of coloured threads. These long lengths are then submitted to the operation of singeing, which has for its object the removal of the downy pile and short threads from the surface of the cloth, which would interfere with the appearance of finished white goods, and with the uniformity and sharpness of patterns in the case of prints. Several methods of accomplishing this have been employed, but that most commonly used is the system of plate singeing illustrated in fig. 4. A pair of

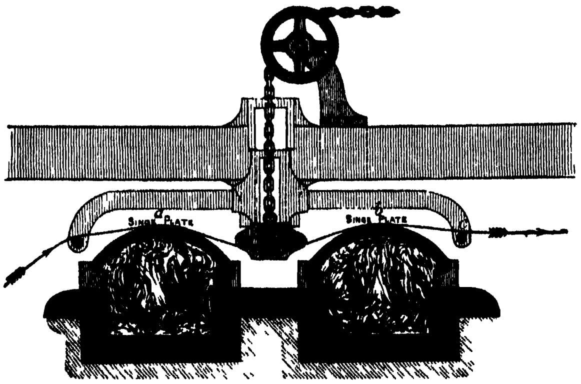

FIG. 4.—Section of Singe-Stove

singe-plates, *a* and *b*, made of thick bent sheets of copper, are mounted over the flues of a fire sufficient to raise a white heat. The plate *b* is most highly heated, *a* being at the end of the flue furthest removed from the fire. The cloth enters over a rail *a*, and in passing over the plate *a* is thoroughly dried and prepared for the singeing it receives when it comes to the highly-heated plate *b*. A block *d*, carrying two rails in the space between the plates, can be raised or lowered at pleasure so as to increase or lessen the pressure of the cloth against the plates, or, if necessary, to lift it quite free of contact with them. The system of plate singeing is found generally sufficient in practice, but the caking of paste and dirt on the plates from the cloth as it passes over them, and variations in the heat of the plates, often lead to irregularities in singeing. A combination of plate and gas singeing is frequently employed to overcome the deficiencies of plate singeing alone. In this case the cloth is passed first over an ordinary plate, and then on to another, along the ridge of which is a long narrow slit, which allows the issue of a gas flame produced from coke burning immediately under it. By this means long loose threads are more effectually burned off than in plate singeing, and a more uniform heat is applied to the gray cloth. Fig. 5 is a sectional view of a very efficient singeing apparatus introduced by Messrs Mather and Platt. The figure represents the first half of the machine, the second portion being precisely similar in arrangement. The singeing in this case is accomplished by the burning of a mixture of coal-gas and atmospheric air admitted by a pipe *a*, and driven by a fan blast to the burners *b*, *b*, which are regulated by stop-cocks. The mixture burns with an

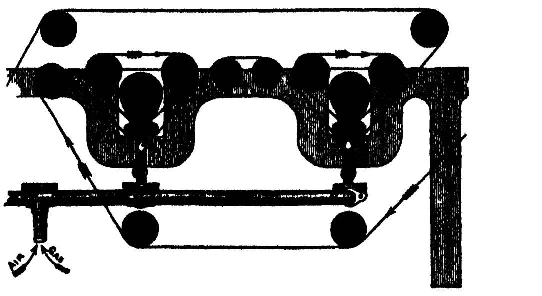

FIG. 5.—Gas Singeing Apparatus

intense heat and a blue smokeless flame. The cloth is carried by a series of rollers to the gas jets, and in passing over the rollers *c*, *c*, *c*, *c* the one side of the cloth impinges laterally four times against the flame, which is never permitted to pass through the fabric, but only shaves its surface. The back is thus singed in the first portion of the apparatus, and being turned over on roller *d* it is carried forward to another pair of jets, where, being thoroughly dry, the face side of the cloth is completely singed by going over exactly the same course through which the back is carried in the first part. By an arrangement not shown in the illustration, the attendant of the machine can instantaneously lower the gas burners by a treadle movement in case of any stoppage or accident, and thus prevent the cloth from being burned. With a proper pressure of gas this machine singes at the rate of 60 yards per minute.

At this stage the cloth has now in addition to the brown coloured incrusting substance and the resinous material proper to the fibre, a dark-coloured carbonized surface, caused by the singeing process, the weaver's paste or dressing, tallow or other fat introduced in the process of weaving, and the accumulation of dirt which the handling of weavers and others may have produced. The object of the subsequent processes is to wash out the mechanical impurities and resinous substances from the cloth, to render soluble by chemical agencies such as are otherwise insoluble in water, and to oxidize the colouring matter of the cotton by the chloride of lime as already explained.

Liming.—In some cases it is the practice immediately after singeing to steep the pieces in water and pile them up wet for a night, in order to loosen and partly ferment the weaver's paste, which is then in large part removed by washing in a machine to be subsequently described. The "gray-backs" which have been used in calico-printing have always to be thus steeped, and at one time it was the practice to leave the cloth so long in this steep that it acquired a most offensive odour. This preliminary steeping and washing facilitates the percolation of the liquor through the fabric in the process of boiling, but notwithstanding this advantage it is generally dispensed with, and the goods pass direct from the singeing to the liming process. The pieces are formed into a loose coil or rope by being passed through circular rings of glass or pottery called "pot-eyes," and worked up and down several times in a strong milk of lime, in order that the whole may be uniformly and thoroughly impregnated. The arrangement for liming will be understood from fig. 6, which is a sectional view of a "squeezer," an apparatus used repeatedly in subsequent operations as well as in this of liming. The cloth passes up and down as indicated by the arrows, dipping several times into the solution, and before passing finally on to the kiers for boiling it is slightly "nipped" between the

"bowls" of the squeezer to extract superfluous moisture. These bowls are thick cylinders of wood, usually in this case made of beech. From the lime squeezer the cloth is carried over winches, and guided through pot-eyes into the kiers.

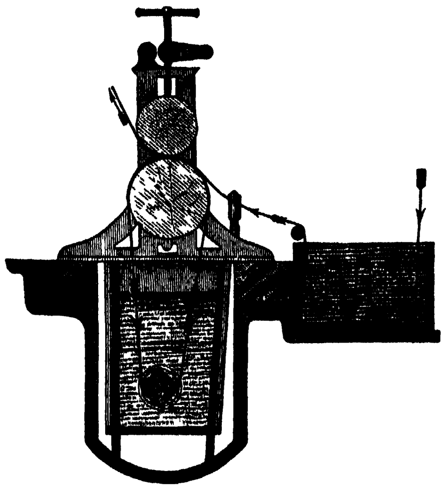

FIG. 6.—Section of Lime Squeezer.

Bowking.—A bowking kier is an apparatus in which the cloth is boiled. To one old form of kier allusion has already been made. Bowking is now mostly accomplished in closed kiers worked up to a considerable pressure of steam. In the boiling for white bleaching about 80 lb of lime are required for 2700 lb of cloth, and the boiling is continued for ten hours at a pressure of about 30 lb. A form of kier very generally employed consists of a strong vessel made of boiler plate, with a man-hole in the upper part, which can be screwed tightly down. The vessel is about 10 feet in depth, and 5 or 6 feet in diameter, and has a false bottom made of a gird of wood or iron, on which the lowest layer of cloth rests. Up the centre of the kier passes a pipe or tube which reaches higher than the cloth can be piled, and is surmounted by an umbrella shaped plate. Steam is admitted at the lower part of the kier,

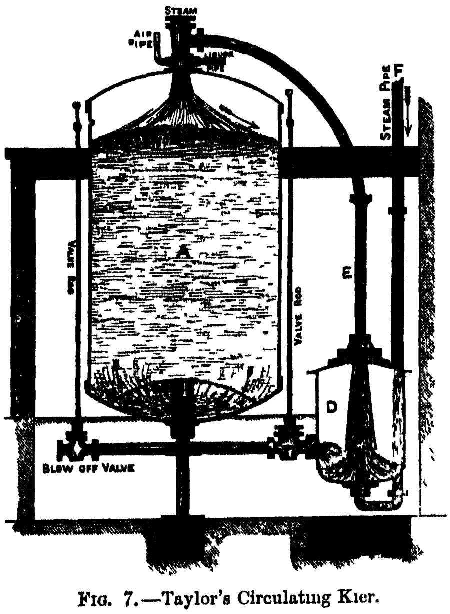

FIG. 7.—Taylor's Circulating Kier.

and as the pressure accumulates it gradually forces the liquor upwards through the central pipe till, by-and-by, it is dashed with great violence against the umbrella-shaped plate, and thrown over the upper surface of the cloth. It gradually percolates down through the cloth to the bottom, where it is again caught and forced up through the central pipe, and thus a constant circulation is maintained. A very efficient circulating kier, the invention of Mr Taylor of Berchvale, has recently been introduced, of which a sectional representation is given in fig. 7. This kier in outline is like the previous, but it has no central distributing pipe. Instead, the liquor is carried by an external pipe to the top of the kier, where it enters and is forcibly thrown against the surface of the cloth. The kier A has a false bottom B as in the previous case, and when filled with cloth and liquor, the liquor percolates by a pipe C into the receiver D, where it finds its own level in the ascending pipe E. Steam is admitted at the lower part of the receiver by the steam-pipe F, and forces the liquor upwards through the pipe E to the top of the kier. The vacuum created in the receiver is supplied from the lower part of the kier, and the flow is facilitated by the pressure of steam from above, and thus a constant steady circulation is maintained. This kier is very useful in cases where a comparatively low pressure is desirable, as in white bleaching, where the coloured headings of the cloth (Turkey red or other coloured threads introduced at the end of a web) have to be preserved.

The bowking apparatus generally used by printers is Barlow's high-pressure kiers, an arrangement in which the kiers are worked in pairs. A pair is shown in fig. 8, one

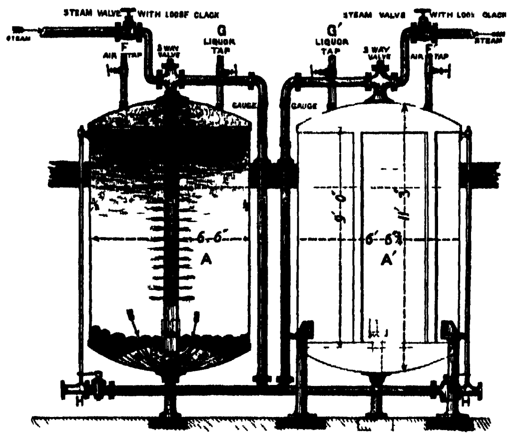

FIG. 8.—Barlow's High-Pressure Kiers.

being seen in section; the dimensions of the vessels are inserted in the figure.

The novelty these kiers introduced when first brought out, was that in using steam of 40 lb instead of 5 lb, a greater economy of time and drugs would be effected. Their world-wide application has proved that the inventor's theory has found ample confirmation. The cloth is carried, or rather drawn by winches, and dropped into the wrought iron boilers or kiers AA′, through the man-holes in the top, two pieces in all cases running side by side. As the pieces are delivered continuously in the kiers, a lad in each spreads a pile of the cloth all round the kier, as equally as possible, so that, when full, the kier shall be packed uniformly to the top. This cloth rests on what is termed a false bottom, simply a grid or plate with holes in it, as shown at B. Upon the grid are generally placed a few smooth stones, through the spaces between which the liquor drains from the cloth.

Down the centre of the kier is a pipe C, perforated with holes, for the purpose of distributing the liquor freely into the mass of cloth. The kiers are connected by a pipe D, leading from the bottom of one to the top of the other, and *vice versa*. The steam is introduced through the valves EE′. After the kiers are filled with cloth, each holding about 6000 lb, the man-hole lids are screwed down and all made steam tight. A little steam is then turned on to discharge the air from the cloth, which escapes through the pipes FF′. This steam, moreover, gradually warms the goods. The alkaline liquor or lime water, having been mixed to the proper strength

is then let into the kier A, through the tap G, until the necessary quantity has been supplied, about 20 gallons of caustic soda at 70° Tw., and 400 lb lime for the full charge being used. The steam is then turned on slowly, and by its pressure the liquor in kier A is made to pass with great force through the cloth, and then up the pipe D, through the 3-way valve, into the kier A'. When all the liquor has passed over, the steam valve E' is reversed, steam is shut off from A, communication is opened to pipe D', and valve E' turned so as to admit steam to A', when the action of forcing the liquor through the cloth up the pipe E' into kier A is performed. This alternate passing of the liquor backwards and forwards, see-saw fashion, through the cloth, constitutes the operation of boiling. The steam also has great effect if left in contact with the cloth for a few minutes in one kier, after the liquor has gone over to the other kier. This process is continued for eight hours (nearly one-third the time formerly required in what are termed low-pressure kiers), with steam of from 30 to 50 lb, during which time the liquor passes about 16 times from one kier to the other; then the valves HH' are opened, and all the liquor expelled by the steam from the cloth into a drain. The steam is then shut off, the man-hole lids removed, and the ends of the two chains of cloth taken out and passed through pot-eyes, which guide the pieces to the washing-machine.[1]

Washing.—The cloth as it issues from the kiers is found to have assumed a very dirty brown aspect. Formerly, the apparatus used for washing was either the wash-stocks or the dash-wheel, to which allusion has already been made. The machine now generally employed is represented in section in fig. 9. It consists of a pair of wooden bowls

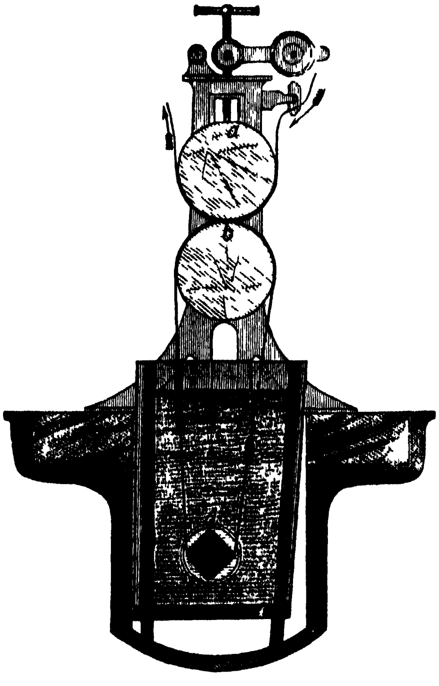

FIG. 9.—Section of Washing Machine.

or cylinders *a* and *b*, about 9 feet long, mounted in a strong framework, and arranged to press against each other in their revolution. Plane tree is the wood most suitable for making these bowls. Running underneath the whole length of the bowl is a box or trough *c* filled with water, near the bottom of which a rectangular roller *d* is fixed. The water in the box is constantly renewed during washing operations by a current flowing in at the middle and escaping at each end. Two chains of cloth are washed in this machine at the same time, one being introduced at each extremity of the roller. The cloth passes down into the water under the roller *d* and up to the wooden bowls, between which it is caught and nipped, and down again into the water, working its way in a spiral manner from the end to the centre of the machine, passing nine times through the water and between the bowls in its progress. Its course inwards is guided by a strong wooden rail, from which pegs project, arranged according to the number of turns to be given to the cloth. In the centre part of the upper bowl there is a lapping of cotton rope, which projects a little above the surface of the wood, and serves to give the cloth, as it finally issues from the machine, a much stronger squeeze than it would obtain between the long even bowls, and thereby expels a large proportion of moisture. As the cloth travels inwards towards the centre of the trough, while the flow of water is outward to escape at each end, the cloth on each revolution is meeting water more nearly pure, till just at the point where it issues from the trough for the last time, the clean water entering the trough is powerfully spurted upon it, thus giving it a thorough rinse before it is finally squeezed. It is usual to pass the cloth from the lime boil either through a pair of such washing-machines, or twice through the same, in order to expel the last trace of calcareous soap and uncombined lime from the texture.

In addition to this machine various other devices have from time to time been proposed and introduced to perform the important operations of washing. Among these the continuous washer of Mr Henry Bridson of Bolton-le-Moors, Lancashire, patented in 1852, is deserving of notice as a simple and efficient washing-machine. Mr Bridson's washer consists of an oblong tank or trough of cast-iron which, in use, is kept about half filled with water. Within this tank, just dipping into the water, two cross shafts are fixed, which are geared to revolve in the same direction by spur-gearing mounted outside the trough. Each shaft carries a pair of discs of large diameter, and between the discs of the two shafts a pair of bars placed diametrically opposite each other are mounted. These bars form flat winces or revolving frames, by the revolution of which the fabric is not only carried forward, but is in its progress caused to strike with great violence against the surface of the water. The intermittent flapping and shaking motion thus communicated to the material has a powerful effect in detaching adhering impurities from the cloth. Another form of washing-machine in use in Lancashire consists of a row of eight vats or troughs arranged in an ascending series, so that the overflow of water from the highest or last runs into the second highest, and so downwards till it escapes from the lowest or first. The cloth enters at the lowest trough, and is carried by guide-rollers up and down through the entire series, issuing at the top between a pair of squeezing rollers.

Gray Sour.—From the washing-machine the chain of cloth is passed through a pair of squeezers, by which a large proportion of moisture is expelled. The operation of souring, which comes next, is performed in an apparatus of the same construction as the washing-machine, the trough under which contains the souring liquor. For white bleaching a solution of hydrochloric acid of a strength of 2° Twaddle (sp. gr. 1010) is used, and for print bleaching the solution is made up to 4° Tw. Through this the cloth is passed up and down twice by the revolution of the bowls, and piled up in the sour in stillages for some hours. The object of the souring is to dissolve any traces of free lime which may have been left in the washing, and to decompose the calcareous soap.

Second Boil.—After having lain in the sour for a sufficient length of time the cloth is passed through squeezers to expel as much as possible of the acid, and again washed in the machine. It is next passed into a kier or set of kiers, precisely as after liming, for the second boil, which in the

[1] For this description of the Barlow kiers we are indebted to Mr William Mather.

case of print bleaching is done with a solution of soda-ash and rosin. For a pair of Barlow kiers boiling 12,000 ℔ of loth, the quantities used are 350 ℔ of soda-ash and 200 ℔ of rosin dissolved with 30 gallons of caustic soda at 70° Tw. The boiling is carried on for ten hours, in a like manner and at the same pressure as in the case of the lime boiling. The soda-ash and rosin form a soap, which dissolves out the free fatty acid in the cloth, and acts on the calcareous soap remaining by forming carbonate of lime and a soluble soda soap. In the white bleaching of 2700 ℔ of cloth, the boiling solution is 8 gallons of caustic soda at 70° Tw., but by some bleachers soda-ash is employed in the proportion of 80 ℔ to 2700 ℔ of cloth. From this boil the cloth is passed on to the washing-machine, and then squeezed, when it is ready for "chemicking" with the bleaching-powder solution.

Chemicking.—When the previous processes have been efficiently carried out, the cloth will, at this point, have attained a considerable appearance of whiteness and purity. The "chemicking" or liquoring with bleaching-powder which it now undergoes is conducted in a similar manner to the souring already described. The chemick is used as weak as possible, the solution varying from $\frac{1}{8}$° to $\frac{1}{4}$° Tw. (sp. gr. 1·000625 to 1·00125) according to the weight and condition of the cloth under treatment. It is run through this liquor, gently squeezed, and piled up for four or six hours. It is then squeezed and washed; and at this stage the bleacher has to judge whether the cloth requires to be chemicked a second time, which, in the case of heavy goods, is frequently necessary. If a repetition of the process is required, the cloth is again passed into the kiers, boiled with a solution of soda-ash, and the other processes repeated as before.

White Sour.—After lying in the chemick the goods are again washed and squeezed, and afterwards soured in machine with sulphuric acid, used at a strength of about 4° Tw. (sp. gr. 1·020), and piled up for a period of at least three hours. Thereafter, in order thoroughly to expel all acid the goods are twice washed, and finally squeezed, which concludes the operation of bleaching proper. The calico should now present a snow-white aspect, and should be fit to take the most delicate shades of colour when it is to be used for printing purposes.

Opening.—In passing through the numerous processes detailed in the foregoing statement, the cloth has been always in the form of a coil or loose rope. In the drawing from one machine to another it has been also pulled somewhat to the length at the expense of breadth, and in places it is likely to have become a little twisted. The pieces have therefore now to be opened out to their full width, and, if necessary, evened. The opening out is effected by passing the pieces to a winch placed at a considerable height when the weight of the cloth itself in passing upwards unfolds it, and the selvedges are caught and extended by a boy just before it passes on to the winch. When necessary it is caught beyond the winch by an opening-machine, such as that patented in 1871 by Mr Wm. Birch of Salford. It is a complex apparatus, working by endless bands, on which are toothed projections, and these, travelling from the centre to the sides in opposite directions, open and spread out the cloth before it passes over the roller which is mounted on the machine. From the opener the cloth passes at once to the drying-machine (hereafter described), after passing over which cloth intended for printing is folded or batched on rollers, and its further treatment belongs to the art of calico-printing.

Finishing.—So far as regards bleaching proper the process is now at an end, and the further operations which white calicoes undergo have only for their object the improvement of their appearance for the market. But although the finishing adds in no way to the quality of the material, it is regarded as of great value by the merchants, and the finish of a bleacher is of more importance than his bleaching. A great variety of finishing operations have to be employed, according to the different qualities of textiles, and the purposes to which they are devoted. Finishes are "beetled," "calendered" (either "stiff," "medium," or "soft," or "glazed,") and, for dress muslins, &c., "elastic." As the processes and appliances for these finishing operations are very numerous and varied, they cannot here be described in detail. In most cases they are the same as used in the finishing of calico prints, and more information will be found under that head. We shall here confine our remarks chiefly to the finishing of ordinary white beetled calicoes.

Water Mangle.—The cloth, when brought into the finishing-room, is passed over a stretching rail into a trough of boiling water and between a series of calender rollers, in which it is powerfully pressed. A common arrangement of the cylinders of the water mangle is to have a series of four, two of small diameter being made of copper, and two larger of condensed cotton; but wooden bowls are also sometimes employed with only a single intermediate copper cylinder. By this mangling process the water is equalized throughout the whole piece, the threads are flattened, and the cloth stretched, smoothed, and wound upon a roller, and thus rendered fit for receiving the starch.

Starching.—It is in this stage that so much is done by some bleachers to give cloth a factitious appearance of weight and bulk by filling up the interstices between the fibres with compounds which have no other object than to please or deceive the eye, and some of which have a decidedly deleterious influence on the tissue they are intended to improve in appearance. A great variety of mixtures, both cheap and nasty, are used by some finishers in place of starch with a view to produce weight and appearance, but, naturally, as little information as possible on this point is permitted to leak out to the public. What ought to be, and by reputable bleachers really is, used is pure starch, either of Indian corn or wheat, or both, made up into a stiff mucilage and blued with ultramarine or indigo. The cloth passes over a stretching rail into a trough of this starch, in which a roller is mounted. As it comes out of the starch it is caught between a pair of bowls, by which the superfluous starch is squeezed out and thrown back into the trough, the cloth passing on to the drying-machine. The starching mangle and drying-machine are seen together in fig. 10.

Drying.—The drying-machine (fig. 10) consists of a

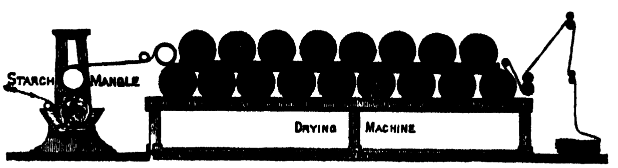

FIG. 10.—Starching Mangle and Drying Cans.

number of cylinders made of tinned iron or copper, and filled with steam of low pressure. The cloth passes alternately back and face over one and the other, and emerges to be placed down at the end perfectly dry. This system of drying was introduced among the first mechanical appliances used in calico-printing, and has not as yet been superseded by any other plan. Various improvements in detail, we learn from Mr William Mather, as to the construction of the cylinders and the mode of applying steam to them have been recently introduced, but the machine remains the same. One important defect has been recently

removed by an alteration in the construction of the cylinders, to prevent collapse, in case a vacuum were formed by the rapid condensation of the steam. A spiral rib or stay is made to run from end to end of the body of the cylinder, giving support uniformly the whole length, and serving at the same time as a screw to drive the condensed water, as the cylinder revolves, to one end, where it is ejected through a nozzle. The steam enters at the nozzle, from the framing which is cast hollow, and serves as a pipe to distribute the steam to all the cylinders in the machine, while the framing on the other side serves in like manner to receive and discharge the water.

Damping.—From the drying cans the cloth is passed on to the damping-machine, where it is uniformly moistened by an exceedingly fine spray of water thrown upon it. The spray is thrown up by a circular brush, the tips of which are allowed to dip into water in a trough over which it revolves. Mather and Platt have introduced a manifest improvement on this plan by throwing the water in fine jets on the brush from a pipe which runs parallel with it. By this means the quantity of water and degree of moisture can be regulated with the utmost nicety. Fig. 11 shows the damping-machine in section as modified by

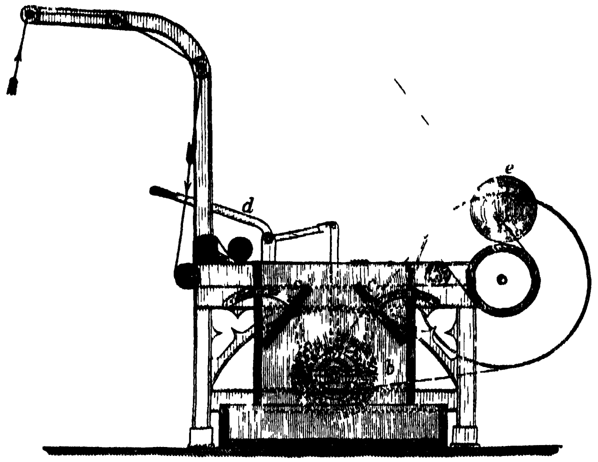

FIG. 11.—Damping-Machine.

Mather and Platt. *a* represents the circular brush revolving in a trough, and *b* is the pipe from which the water is squirted on the brush. The spray from the brush is confined by two sloping boards *c*, *c*, which work on quadrants, and the lever *d* raises or depresses the brush at

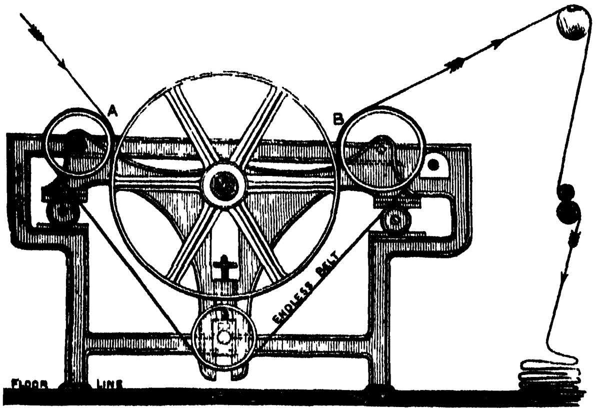

FIG. 12.—Elevation of Belt-Stretching Machine.

pleasure. The course of the cloth over the machine is indicated by arrows, and after damping it is batched on an iron or wooden beam *e*, when it is ready for the process of beetling. When goods are to be finished of any particular width, they are at this stage breadthened by such an apparatus as the belt-stretching machine of Mather and Platt shown in elevation in fig. 12 and in plan in fig. 13. In

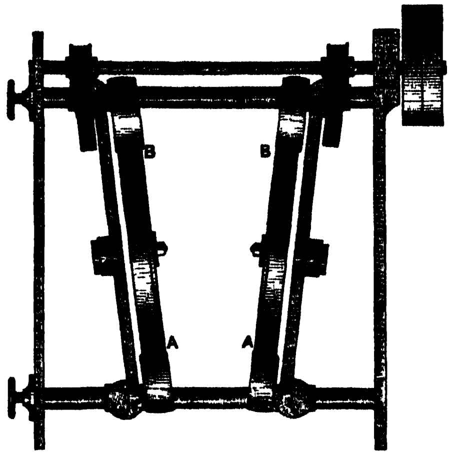

FIG. 13.—Plan of Belt-Stretching Machine.

this machine the full width of the cloth is obtained by the selvedges being held firmly by a belt and pulley on each side, the pulleys revolving at such an angle that the stretch on the cloth has to compensate for the difference in distance between these pulleys at A and B.

Beetling.—The beetles ordinarily employed are a series of long heavy wooden piles arranged in a frame. These piles are alternately raised and allowed to fall with their full weight against the beamed cloth by the revolution of a roller having a spiral series of notches, which catch a corresponding range of projections on the piles. The beam with the cloth is made to revolve gently by a ratchet motion as it is submitted to this hammering, which goes on for two or three hours. Recently Mr John Patterson of Belfast has patented and introduced a form of beetling-machine (fig. 14), which from its highly effective action

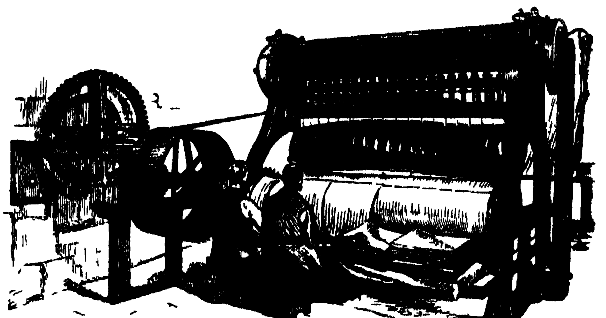

FIG. 14.—Patterson's Patent Beetle.

is likely to come into very extensive use. The advantages claimed for his machine over the common beetle Mr Patterson thus states: "Heretofore, the beetling of textile fabrics has been done by means of beetles, or stampers, falling upon the fabric by the action of gravitation, each stamper or beetle falling 55 or 60 times per minute through a space of 13 to 15 inches. This rate of speed cannot be accelerated by gravitation, and the consequence has been that in order to increase the quantity of work done by the ordinary beetles, very bulky and massive machinery has been employed, requiring large and expensive buildings and driving gear. The new beetling-machine requires not one-tenth of the space, very much lighter gearing, and

instead of making 60 blows per minute, each beetle makes from 420 to 500 blows per minute. The blows are not by the action of gravitation, but are actuated by a series of cranks cut upon a solid steel shaft. There are connecting rods from the steel cranks to semicircular springs. The beetles are attached to, or suspended between, the points of the semicircular springs by means of leather straps. When the crank shaft is set in motion the beetles are snatched up in regular sequence by the upward motion of the cranks, and the springs are compressed by the weight of the beetles, as in fig. 15, and by the combined upward motion of the cranks and the springs the beetle is thrown upwards with great impetus. The upward motion is stopped as the cranks pass the top centres, and the beetles are thus met by the springs and thrown violently into them, causing them to be again compressed, as in fig. 16.

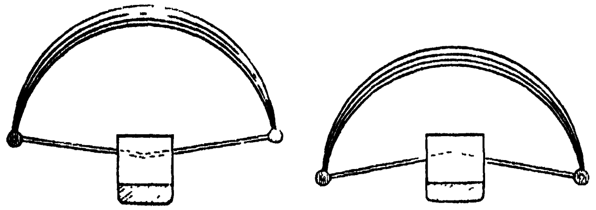

FIG. 15. FIG. 16.
Hammers of Patterson's Beetle.

When by the downward motion of the cranks the springs are allowed to throw the beetles on the cloth beam, a rapid forcible whipping blow is imparted to the cloth, which does not cut or injure it in the manner often done by the slow dropping blows of the ordinary beetles. The weight of the blows can be instantly varied by varying the speed of the crank shaft, from the slightest touch to the heaviest penetrating blow. It is found that twice or thrice the number of folds of cloth can be beetled effectively on the cloth beams more than can be done on ordinary beetles, that is, instead of 200 folds on the beam, 400 or 600 folds can be equally well beetled on the new machine."

Calendering.—When it is desired to finish cloth with a stiff or with a glazed finish, instead of being submitted to the operation of beetling, it is finished in the calender. The calender, as its name κύλινδρος implies, is a series of cylinders mounted above each other in a strong framework. The number of cylinders and the material of which they are constructed vary. In some only three cylinders or bowls are employed, and in others they are four or five. One or two of the bowls are made of metal, and two or three are either of wood, of condensed cotton, or of paper, and they must always be turned with great accuracy and be free from all warping. Cylinders of paper or condensed cotton have a very smooth surface and a considerable amount of elasticity. Between these cylinders the cloth as it comes from the damping-machine is passed, and twice, thrice, or four times, according to the construction of the calender, it is powerfully pressed. The pressure gives the cloth a very even surface, condensing the fibres, and produces a shining lustre. When the cloth is submitted to friction, as well as to pressure in a heated calender, a glazed finish is produced. The frictional effect is produced by the cylinders being geared to move at different rates of rapidity, so that in their revolution they rub over the surfaces of each other in addition to communicating pressure. Fig. 17 shows a finishing or friction calender in section. The metal cylinder *a* is made hollow so that it may be heated by the introduction of steam or gas, *b* and *d* are of compressed cotton or paper of the same diameter as *a*, and *c* is a smaller metal cylinder. The pressure of the cylinders is regulated by means of the screw *e*, and the compound lever *f*, which is adjusted by the double screw on the connecting rod at *g*. The cloth enters over stretching rails and rollers, passes through the calender in the manner indicated by the arrows, and is batched on roller *h*.

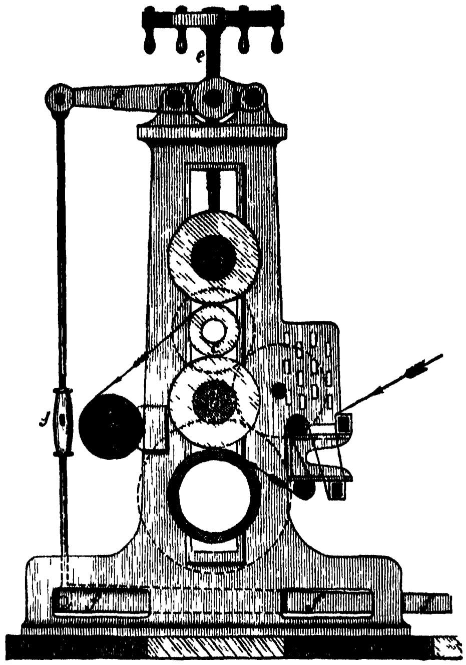

FIG. 17. Section of Calender.

Elastic Finish.—This particular kind of finish is applied to muslins and similar thin fabrics, and has to be done in highly-heated apartments called stentering stoves. Formerly the work was entirely done by manual labour, and consisted in holding the fabric by the selvedges, and pulling it forward and backward while it was drying in the heated air. In this way the threads were made to rub against each other, and the cloth was thus deprived of the hard, stiff board-like appearance it would have possessed if left motionless when drying. Mr Ridgway Bridson was the first who introduced a machine which successfully supplanted hand labour in producing the elastic finish in muslins. His stentering frame is thus described :—Two horizontal rails or frames extend side by side the whole length of the machine, carrying at each end a large wheel or pulley, with small pins fixed at equal distances in its periphery. These pins pass through corresponding holes in an endless band which passes round the pulleys. On the surface of the endless bands are fastened very fine needle or tenter points to hold the selvedges of the fabric as it passes through the machine. The horizontal rails can be moved away from each other laterally, so as to stretch the fabric breadthwise. The rails are of equal length with the fabric to be treated, which is fastened by the selvedges at one end to the centre pins, and the pulleys being set in motion, the entire piece is carried on and stretched out over the machine, and the rails are then moved outwards to breadthen the fabric. The elastic finish is given by communicating alternate vibrating motions to the two rails, by which a diagonal stretching is given to the muslin while in the process of drying.

At the conclusion of any of these various finishing processes, the goods are folded either in a plaiting-machine or by girls hooking plaits of definite length by the selvedges on steel spikes. The end of each separate piece is then stamped with some device or motto intended to serve as a trade mark. After the goods have been regularly folded, they are placed piece by piece, separated by sheets of

pasteboard, in a Bramah press, and after a certain interval an iron plate is substituted for the pasteboard, to prevent any inequality in the pile. Finally, the folded pieces are prepared for the market by fastening a band of gilt and ornamented paper around each end, which with the imprinted device is in some way regarded as a guarantee of good quality.

The whole operations of bleaching and finishing occupy on an average eight days, although goods can be hurried through much quicker if occasion arises. The cost, which of course will vary with the price of fuel and other circumstances, is very small as compared with the value of the material, and does not on an average, for shirting calicoes and the like, exceed 1½d. per ℔ weight of cloth.

Bleaching of Thread.

We have been favoured by Messrs J. and P. Coats of Paisley with the following outline of the processes in the bleaching of thread :—

1. The various Nos. of thread are prepared before boiling.
2. The first boil. The kier used is a common vomiter, into which are put water and a solution of caustic lye,—the proportions being regulated by the number of pounds of thread to be treated.
3. The first bleach. The thread is placed in a box, and a sieve let down upon it. Underneath the box is a well which is filled with water and chlorine. The liquor is drawn up by a pump, and thrown upon the sieve, through which it passes, and filters through the thread into the well.
4. The thread is next moved into a souring-box, also covered with a sieve, where it is washed to take out the chlorine of the previous process.
5. A souring-well under the souring-box is now filled with water and sulphuric acid, and this mixture, called the *sour*, is pumped up on the sieve over the souring-box, through which it runs back into the souring-well, in the same manner as described in process No. 3.
6. Before removing the thread from the souring-box it is washed with water through the sieve.
7. It is next washed in a washing-machine.
8. The scald, or second boil in kier. Various mixtures are used for it. Some prefer black soap and crystals of soda; others use caustic lye.

9–13. Repetition of Nos. 3, 4, 5, 6, and 7.

14. The thread is now extracted, *i.e.*, dried in hydro-extractors.
15. Stocking. The stocks are boxes about 3 ft. long, by 2 ft. wide, and 2 ft. deep, with a large wooden mallet hung in each, similar to those used in bleaching linen. The thread hanks having been properly prepared, so that they will not get loose, are put into the stocks with a mixture of hot soap and water, and beat there till of the proper colour. It is then taken out, and
16. Washed in washing-machine, and
17. Extracted.
18. The blueing process is done in a box filled with a solution of water and extract of indigo. As much thread is put in as the box will contain. It is let stand for a time, after which it is taken out and thrown on a barrow.
19. It is next taken to extractor and dried, and
20. Placed in the stove. After being a sufficient time there it is
21. Removed to cooling shed, where it is hung up to cool.
22. It is now taken to stretching-machine, where it is passed over hot rollers to take out the curl and moisture received in cooling shed.
23. Taken to warehouse, where Nos. are classed and made up in bundles.

Bleaching of Linen.

The bleaching of linen is a much more tedious and difficult operation than the bleaching of cotton. The process of water-retting, or rotting, by which the fibre is separated from the woody portion of the stalk, lodges a large proportion of colouring matter in the fibre, with which it enters into very intimate combination. The amount of colouring matter which has thus to be dealt with in the bleaching of linen is very great, being as much as one-third of the entire weight of the fibre. In the early part of the century a great amount of public attention was given to a plan proposed by Mr James Lee for preparing flax fibre without the process of steeping or retting, by which it was affirmed that, among other advantages, it would only be necessary simply to wash, in soap, linen fabrics made from fibre so prepared, to render them pure and white. Mr Lee obtained a special Act of parliament allowing the specification of his patent to remain sealed for seven years, and his plans were entered into in a most full and laborious manner by the Irish Linen Board. After the expenditure of many thousands of pounds on his machines and experiments, the plan had to be entirely abandoned as a failure. More recently, Chevalier Claussen renewed the attempt to prepare flax without steeping, by breaking it by means of machinery, separating the refuse part of the stalk from it, and then by a chemical process splitting the hollow fibres, so as to reduce them to a soft cottony state fit for spinning by means of the cotton-spinning machinery. The fibre was proposed to be split by steeping the prepared flax in a solution of carbonate of soda, and then plunging it into dilute sulphuric acid. The sudden evolution of carbonic acid gas within the hollow tube of the flax was said to have the effect of splitting up the fibre and reducing it to fine flat threads possessing the felting properties of cotton. Sir Robert Kane, in his Report to the House of Commons, May 20, 1852, states that the whole process failed. The machinery for the beating and cleansing of the flax failed to separate it sufficiently from the refuse part of the stalk; and the chemical process for the splitting of the hollow tube only broke up small portions of the exposed ends, leaving the greater portion untouched. Various other plans of preparing flax fibres without water or dew-retting have from time to time been proposed and patented, but hitherto none of them has stood the test of extended practical operation. Till towards the end of last century the bleaching of linen both in the north of Ireland and Scotland was accomplished by bowking in cow's dung and souring with sour milk. In the year 1764 Dr James Ferguson of Belfast received a premium of £300 from the Irish Linen Board for the application of lime in the bleaching of linen. Notwithstanding this reward the use of lime in the bleaching of linen was for a long time afterwards forbidden in Ireland under statutory penalties, and so late as 1815 "Mr James Barklie, a respectable linen-bleacher of Linen Vale, near Keady, was prosecuted for using lime in the whitening of linens in his bleach-yard." The bleaching of linen to the present day is conducted much more in the primitive fashion of last century than is the practice with cotton-bleaching. Owing to the stiffness and inelasticity of flax fibres, a great part of the machinery used for cotton is not available for linen, and solutions of acid and bleaching-powder require to be used in a very dilute condition for linen fabrics, involving frequent repetitions of the various processes before a satisfactory white is produced. "Crofting," or exposure to the air on grass, is also very largely resorted to in the bleaching of linens, especially for plain shirting and sheeting, which necessitates the possession of very extensive grass parks in connection with works, and renders the process both tedious and subject to the influences of the weather. A large proportion of linen cloth is half-bleached or improved in the yarn before being woven, and it consequently requires less bleaching than that which comes in its original "green" condition. The following is an outline of the two chief methods, with and without crofting, as pursued in the principal Scotch linen bleachfields at the present day :—

I. Without Crofting.

1. Limed.
2. Boiled in open kier for about 6 hours.
3. Washed at washing-mill or stocks.
4. Soured with hydrochloric acid, and piled in sour for some hours.
5. Washed at stocks.

6. Boiled in soda-ash for 8 or 10 hours.
7. Again boiled.
8. Liquored in chlorine solution and piled up.
9. Washed.
10. Boiled in alkali for 6 or 7 hours.
11. Liquored in chlorine solution.
12. Washed.
13. Soured with sulphuric acid.
14. Washed.

When necessary the processes from 10 to 14 are repeated. The whole processes occupy, on an average, four weeks.

II. With Crofting.

1. Boiled in lime.
2. Washed.
3. Soured.
4. Washed.
5. Boiled in alkali and washed.
6. Exposed on grass 3 or 4 days.
7. Boiled in alkali.
8. Washed.
9. Exposed on grass.
10. Liquored.
11. Washed.
12. Soured with sulphuric acid.
13. Washed.
14. Boiled in alkali.
15. Liquored.
16. Washed.
17. Soured with sulphuric acid.
18. Washed, and processes 14 to 18 repeated if required.

With exposure on the grass the bleaching of plain linens usually occupies from 4 to 6 weeks. The finishing processes are essentially the same as in the case of calicoes. The following are the stages in finishing linen damasks:—

1. Nipped in squeezers.
2. Blued in ultramarine in blueing-water mangle.
3. Starched in starching-mangle.
4. Dried on steam cans.
5. Damped with fine spray.
6. Beetled.
7. Calendered.
8. Dried on steam cans.
9. Again calendered.
10. Viewed to detect rust spots and holes.
11. Lapped.
12. Pressed in hydraulic-press.

Charles Tennant of St Rollox made some experiments in 1831 to determine by which parts of the process the chief loss was sustained during bleaching. The result was that in 1000 parts by weight, linen yarn lost—

In the now abandoned fermenting alkaline steep	57 parts.
In 4 boils with caustic soda	70 ,,
In 4 steeps with chloride of lime	170 ,,
In 4 steeps in the sour	18 ,,
Total	615 parts in 1000.

Bleaching of Paper-Making Materials.

In addition to cotton and linen rags, esparto or Spanish grass (*Macrochloa tenacissima*) is now very largely used for the manufacture of the better classes of paper. Wood, especially the wood of the aspen (*Populus tremula*), is also now applied as a paper-making material. Jute has been used for printing paper, and straw is very largely employed, but chiefly for brown and packing papers. These and the numerous other substances used for paper-making are all reduced to the condition of "half-stuff" before they come to undergo the operation of bleaching, and the treatment they receive in this stage varies only in the amount of whitening required, and consequently in the proportions of bleaching solution used. It is therefore unnecessary to notice more than the process followed in the bleaching of the "half-stuff," which in Great Britain is very frequently prepared from a mixture of esparto fibre and rags. The bleaching solution of chloride of lime is either prepared in specially constructed cisterns, fitted with revolving agitators and stored in a reservoir for use, or prepared for immediate use in a wooden vessel. When the solution is made up to the requisite strength, and all insoluble sediment has sunk to the bottom of the vessel, it is ready for pouring into the engine. From 4 to 10 ℔ of ordinary bleaching-powder are used for every 100 ℔ of rag half-stuff, but a much larger proportion is required for esparto. Sulphuric acid in not more than a proportion of 1 ℔ to 4 ℔ of bleaching-powder is thereafter added in a highly dilute condition, and the whole, after mixing in the engine, is turned into the drainer, which is a large tank provided with a false bottom of perforated wood covered with wire-netting or bagging. In some cases the bleaching-liquids are not added to the pulp material till it is deposited in the drainer; and the acid solution may be poured in first, or both solutions may be alternately used in small quantities. The bleaching process is sometimes carried on in separate engines constructed of materials not affected by the corrosive action of acid substances. Drained half-stuff may also be bleached in a suitable apparatus by the direct application of chlorine gas.

It is of the greatest importance to free the pulpy material from the last traces of chlorine before it is made into paper, as it would react upon the manufactured product and render it brittle. To eliminate the free chlorine and acid, &c., the pulp is washed in the beater with pure water till it ceases to redden litmus paper, or give other characteristic indications of the presence of such compounds. The prejudicial effects of chlorine and its combinations are also overcome by the addition of "antichlor," the hyposulphite of soda or of lime, which forms with them compounds that do not affect the colour of the paper, although it is desirable, as far as possible, to remove such compounds also by washing with water.

Bleaching of Straw.

The fine wheat-straw used in Tuscany and elsewhere for straw-plaiting, after being cut, dried, and tied up in bundles, is stacked for a month. It is then spread out in a meadow, and exposed to the action of the sun and air, being frequently turned during that period. The lower joint of the straw is then separated, leaving only the upper joint with the ear attached,—this being the only part of the straw used. It is then steamed, and after that exposed to the action of sulphurous acid gas prepared by burning sulphur, which complete the bleaching. It is then tied up in bundles, in which state it is ready for the market. In the strawplait-making centres of Great Britain—Luton, Dunstable, &c., in Bedfordshire—straw is bleached, chiefly after plaiting, by the influence of sulphurous acid gas.

Whitening and Cleaning Prints, Maps, Books, and other Articles of Paper.

Chlorine was first applied to this purpose by Chaptal, and his method was employed with the greatest success by Vialard and Heudier, who by Chaptal's process restored several of the most valuable books of the French National Library. Chaptal's *modus operandi* is thus described in his own words:—

"They begin by unsewing the book and separating it into leaves, which they place in cases formed in a leaden tub, with very thin slips of wood or glass, so that the leaves, when laid flat, are separated from each other by intervals scarcely sensible. The acid is then poured in, making it fall on the sides of the tub, in order that the leaves may not be deranged by its motion. When the workman judges, by the whiteness of the paper, that it has been sufficiently acted upon by the acid, it is drawn off by a cock at the bottom of the tub, and its place is supplied by clear fresh water, which weakens and carries off the remains of the acid, as well as its strong smell. The leaves are then to be dried, and, after being pressed, may be again bound up.

"The leaves may be placed also vertically in the tub; and this position seems to possess some advantage, as they will then be less liable to be torn. With this view I constructed a wooden frame, which I adjusted to the proper height, according to the size of the leaves which I wished to whiten. This frame supported very thin slips of wood, leaving only the space of half a line between them. I placed two leaves in each of these intervals, and kept them fixed in their place by two small wooden wedges, which I pushed in between the slips. When the paper was whitened, I lifted up the frame with the leaves, and plunged them into cold water, to remove the remains of the acid, as well as the smell. This process I prefer to the other.

"By this operation books are not only cleaned, but the paper acquires a degree of whiteness superior to what it possessed when first made. The use of this acid is attended also with the valuable advantage of destroying ink spots. This liquor has no action upon spots of oil, or animal grease; but it has been long known that a weak solution of potash will effectually remove stains of that kind.

"When I had to repair prints so torn that they exhibited only scraps pasted upon other paper, I was afraid of losing these fragments in the liquid, because the paste became dissolved. In such cases I enclosed the prints in a cylindrical glass vessel, which I inverted on the water in which I had put the mixture proper for extricating the oxygenated muriatic acid gas. This vapour, by filling the whole inside of the jar, acted upon the print, extracted the grease as well as ink spots, and the fragments remained pasted to the paper."

A solution of peroxide of hydrogen (H_2O_2) has been used with great success in the restoration of valuable prints, as well as for cleaning and reviving oil painting darkened by the action of sulphurous vapours.

Bleaching of Wool.

The bleaching of wool and animal fibres generally is a much simpler and less important operation than is the whitening of vegetable fibres. Wool is covered with a peculiar varnish or greasy matter which impairs its qualities, and which it is the object of the bleacher to remove. To this varnish the name of "yolk" or "suint" is given. It is a fatty unctuous matter, chiefly derived from the cutaneous perspiration, but, no doubt, also secreted by the pores of the wool itself; and it imparts that peculiar heavy odour to sheep with which all must be familiar. From the researches of Vauquelin it would appear that this unctuous varnish consists chiefly of a kind of soap, together with a small quantity of waxy matter, a peculiar odorous animal substance, a mixture of potash salts, and a little lime. This varnish, in consequence of its soapy nature, is soluble in water, so that washing in pure water would remove the greater portion of it; but it is found more advantageous to remove it by the process termed "scouring."

Scouring is performed by means of an ammoniacal lye, prepared of river or other soft water mixed with stale purified urine, which is found to contain a large quantity of ammonia, upon which its action probably depends. The mixture is heated by steam to a temperature at which the hand of the workman can be easily held in it for a considerable time. In this bath the wool is left for from half an hour to two hours, according to the quantity of greasy matter it contains. It is then to be taken out and drained into a basket, so that the drainings may drop into the vessel in which it was steeped, that nothing may be lost. It must now be completely rinsed by exposing it in baskets to a continuous stream of clear water, while a workman is perpetually employed in stirring it with a pole, till the water passes off perfectly clear. As a substitute for urine pig's dung is sometimes used, and various other substances have been proposed and introduced, such as ammoniacal salts, soda-ash, phosphate of soda, and soluble glass. Recently a machine, Petrie's wool-washer, has been introduced for scouring wools. It consists of a range of three or four long tanks, clean water entering at one end of the series and flowing through the whole. The wool is introduced at the end of the range where the water escapes, and where it is consequently most highly charged with the impurities of the washing process, and it is carried forward from one tank to another till it is lifted out at the point where the pure water enters.

It is known that the wool is properly scoured by its filaments being smooth, long, slender, white, and perfectly free from foreign substances, and not having lost their natural tenacity. If this scouring be properly done there is no need of further washings in soaps, or otherwise, till the wool is subjected to the process called "sulphuring"; and in point of fact it is very rarely passed through any other process. Some, however, recommend for the finer wools, where a very delicate white is wished, that they should be passed through one, two, or more baths of soft soap. No caustic alkaline lyes can be employed, as they destroy the wool altogether, dissolving it, and forming with it a kind of soap.

The process of sulphuring is applied to yarns and woven goods only when they are intended to be finished white or light bright colours. Formerly, the method of sulphuring woollen goods was to expose them in a close apartment to the vapour of burning sulphur. The goods were hung on poles, and when the chamber was filled, a quantity of sulphur placed in very flat and broad dishes was allowed to burn away gradually in the chamber, while every aperture by which the vapour could escape was carefully closed. After exposure to the sulphurous acid vapours from six to twenty-four hours the bleaching process was complete, and the goods withdrawn from the chamber. The same process is now much more expeditiously performed by Thom's sulphuring process. The goods are passed on a long chain up and down over a series of rollers in a small chamber filled with sulphurous acid vapours, and a few minutes suffice for the operation. Sulphite of soda acidified with hydrochloric acid is also used in France for the bleaching of woollen fabrics.

Cloth which is to be finished white after the sulphuring process is run through a bath containing some indigo carmine, which increases the brilliancy of the white. When it is to be dyed it is treated with dilute sulphuric acid, thoroughly washed, and dried.

Bleaching of Silk.

Raw silk is covered with a kind of varnish, the nature of which was first thoroughly investigated by M. Roard. He showed that this varnish, instead of being a gum, as was usually believed, resembled a mixture of bees' wax and oil, with a resinous colouring matter, and in raw silk constituted 23 or 24 per cent. of the weight. The varnish is soluble in water, and affords a solution which forms a lather like soap. The yellow varnish is of a resinous nature, and is insoluble in water, but is soluble in alcohol. The waxy substance exists in all silks, but the whiter the silk the less wax does it contain.

The comparative composition of yellow and white raw silk is shown by M. Mulder's analysis:—

	Yellow.	White.
Fibroine	53·37	54·04
Gelatine	20·66	19·08
Albumen	24·43	25·47
Wax	1·39	1·11
Colouring matter	0·05	...
Fatty and resinous matter	0·10	0·30

This varnish, or "gum," as it is technically called, gives the silk a stiffness and elasticity which, for many of the purposes to which silk is applied, it is desirable to remove. This is called "ungumming" by the bleachers of silk. Through many different processes have been suggested for this purpose, none seems to answer so well as the old process of scouring in a weak solution of soap. If, however, the silk be kept in the soap too long after the varnish is removed, it begins to lose body, and has its qualities impaired, becoming dull, stiff, and discoloured, in consequence of being partly dissolved. White or yellow silks many be completely scoured in one hour in the soap bath, using about 15 ℔ of water for each pound of silk, and a suitable quantity of the finest soap. The soap and silk should be put into the water half an hour before it is brought to the boiling point, and then be boiled one hour. They are then removed, wrung out, washed in pure water, and either exposed to the vapour of sulphur or passed through a solution of sulphurous acid gas in water.

The following is the process usually followed by the scourer of silks. A quantity of water is put into a boiler over a fire, and for every 100 ℔ of silk to be scoured, 30 ℔

of very fine soap are dissolved. The solution is generally boiled; but before the silk is put into it, the heat must be lowered to about 90° Fahr., and at this temperature it must be kept during the process. The silks are to be hung in the liquor on rods or frames, and left till the gum is sufficiently destroyed,—care being taken to alter their position now and then, so that every part may be exposed to the action of the bath. When perfectly ungummed, they are flexible and of a dull whiteness; in this state they are to be wrung out to clear them of the soapy water, then well shaken, and put into coarse linen bags, in parcels of from 20 to 30 ℔ each.

These bags are now to be steeped in a fresh bath, or, as the workmen say, are to be baked. The bath is prepared in a manner and proportion much as before, except that the quantity of soap may be somewhat diminished as the heat is to be increased; for the silk is now to be boiled for an hour and a half, taking care to keep the bags from sticking to the bottom of the boiler, by frequently stirring them with a stick. For silk that is intended to be dyed, the former steeping in the lukewarm soap-bath is unnecessary, and the boiling only is employed, using a greater quantity of soap in proportion to the fineness of the colour. After boiling the silk is wrung as before, and then washed, and if it is found to be not sufficiently or not uniformly scoured, it must be submitted to a fresh bath.

The white silk usually sold has a bluish shade given it by a bath impregnated with litmus or indigo. This is prepared by dissolving a pound and a half of fine soap in about 90 gallons of water, in which a small quantity of litmus or indigo has been diffused. This process gives to the silk the tints known by the names of "silver white," "azure white," and "thread white," according to the depth of shade which has been imparted. The "China white" tint is given by adding arnotto to the bath instead of indigo.

From these processes the silk acquires a tolerably clear white, but the highest degree is given to it by the action of sulphurous acid, the silk being either, as is usually the case, subjected to the acid in the state of vapour, or immersed in a solution. At Lyons no soap is used in the tinting process; but, after being boiled, the silk is washed, wrung dry, sulphured, and then passed through water properly blued.

Bleaching of Bees'-Wax, &c.

Bees'-wax in its raw condition, as it is first melted up from the comb, is a yellowish coloured substance somewhat greasy to the touch, and having a faint honey-like odour. It often contains mechanical impurities, besides traces of honey, and to remove these and discharge the colour the following process is adopted:—The wax is broken up into small pieces and melted in a copper boiler, with water sufficient to keep it from burning. When melted it is run into a tub containing hot water, and while in the hot fluid condition the mechanical impurities it may have contained subside to the bottom. From this tub the melted wax flows into a vessel, the bottom of which is perforated with small holes. Through these thin streams of wax are received on a cylinder kept revolving in water below; and thus fine threads of solid wax are produced. These are exposed on moistened sheets to the air and light for some days, during which they are occasionally turned and watered. By this exposure the wax loses much of its colour. It is then melted up into solid blocks and left for some time, after which the operations of melting, forming into threads, and bleaching in the light are repeated till it has attained a pure white translucent lustre, is of very firm consistency, and is free from all odour. Yellow wax is also decolorized by treatment with nitric acid; but chlorine, although it bleaches most expeditiously, is not available, as it leaves traces incorporated with the wax, which on burning evolves irritating fumes of hydrochloric acid. Palm oil, used in the manufacture of soap and candles, is bleached by the action of bichromate of potash and acid.

For bleaching generally, but especially for the bleaching of animal fibres and substances, the use of a considerable variety of processes, and of chemicals other than chlorine and sulphur compounds, have from time to time been proposed and to some extent put into operation. To some of these proposals incidental allusion has already been made, and generally their success has not been such as to warrant special notice. Among other substances which have been recommended for scouring wools and silk are feeble solutions of sulphides of sodium and of potassium, or aluminates of these alkalies, the cyanide of potassium, and a mixture of common salt and oxalic acid. The alkaline permanganates have also been frequently regarded as hopeful bleaching chemicals; and a few years ago the permanganate of potash was introduced and used by MM. Tessié du Motay and Maréchal, who, in connection with the permanganate, used a solution of the peroxide of hydrogen. To this latter substance a peculiar bleaching application has recently been given. Under the name of *golden hair water*, or *auricome*, a liquid is sold by hair-dressers which is found to hold in solution a large percentage of peroxide of hydrogen. The use of this solution gives to the hair the brilliant golden yellow tinge which has come to be regarded as a highly fashionable colour. Other applications of this powerful oxidizing and reducing agent have been suggested by its toilet use, and it has been employed for the bleaching of ornamental feathers, hair, &c. Doubtless, if it could be prepared in stable solution at moderate price it would be found extensively useful in bleaching and other industrial applications. It has also long been hoped that a means of applying ozone as a direct bleaching agent might be devised, but hitherto little success has been attained in this direction. In Germany ivory is bleached by steeping it a week in light naphtha or other volatile oil, and exposing it thereafter to the air and sunlight, by which the atmospheric oxygen becomes ozonized in contact with the ivory and thus whitens it. (J. PA.)

BLEEK, Friedrich, one of the greatest Biblical scholars that Germany has produced in modern times, was born on the 4th July 1793, at Ahrensbok, in Holstein, a village near Lübeck. While attending the elementary school there, he gave evidence of such ability that his father sent him, after he had acquired some knowledge of Latin and Greek, in his sixteenth year, to the gymnasium at Lübeck, where he spent three years, and there imbibed so great a love for the languages of antiquity, that he abandoned the idea of a legal career, which he had once entertained, and resolved to devote himself to the study of theology. After spending some time at the University of Kiel, he repaired to Berlin, and there, from 1814 to 1817, enjoyed the instructions of De Wette, Neander, and Schleiermacher. The teaching of these distinguished men, especially of the last named, exercised a decisive influence upon the whole of his after life. So highly were his merits appreciated by his professors—Schleiermacher was accustomed to say of Bleek that he possessed a special *charisma* for the science of "Introduction"—that in 1818, after he had passed the

necessary examinations for entering the church, he was recalled to Berlin to occupy the position of *Repetent* or tutor in theology, a temporary post which the theological faculty had obtained for him, with a view of retaining his services in connection with that department of the university. In this position, besides discharging his duties in the theological seminary, he published, in Schleiermacher's and Lücke's *Journal* (1819, 1820, 1822), two dissertations, one on the "Origin and Composition of the Sibylline Oracles," and another on the "Authorship and Design of the Book of Daniel." These articles attracted much attention, and were distinguished by those qualities of solid learning, thorough investigation, and candour of judgment, which characterized all the productions of his pen. Bleek's merits as a rising scholar were recognized by the minister of public instruction, who continued his stipend as *Repetent* for a third year, and promised further advancement in due time. But the attitude of the political authority underwent a change. The excitement caused in academic circles by the dismissal of De Wette from his professorship in 1819, in consequence of certain injudicious expressions in the letter of sympathy which he had written to the mother of Sands, the murderer of Kotzebue, had not died out, and the odium and punishment which fell upon De Wette were shared in a greater or less degree by his friends. Bleek, who had been a favourite pupil of the banished professor, incurred the suspicion of the Government as one who was believed to hold extreme democratic opinions. Not only was his stipend as *Repetent* discontinued, but his nomination to the office of extraordinary professor, which had already been signed by the minister Altenstein, was withheld for two years. The mystery at last was cleared up. Bleek had been confounded with another individual of a similar name, one Baueleven Blech. Tardy justice was at length done, and in 1823 Bleek received the appointment to which his merits so well entitled him.

During the six years that Bleek remained at Berlin he twice declined a call to the office of ordinary professor of theology, once to Greifswald and once to Königsberg. In 1829, however, he was induced, on the death of Lücke, to accept his chair in the recently-founded university of Bonn, and entered upon his duties there in the summer of the same year. For the space of thirty years he laboured with ever increasing success, attracting students to his lectures, not by any attractions of manner nor by the enunciation of novel or bizarre opinions on theological subjects, but by the soundness and thoroughness of his investigations, the remarkable impartiality of his critical judgments, and the exceeding clearness of his method of presentation. In 1843 he was raised to the office of consistorial councillor, and was selected by the university to hold the office of rector, a distinction which has not since been conferred upon any theologian of the Reformed Church. After a long and honoured academic life he died suddenly of apoplexy on the 27th February 1859, having been able to lecture to his students as usual on the previous day.

Bleek's works belong entirely to the departments of Biblical criticism and exegesis. His great merits as a critic and exegete consist, as has been already observed, in the thoroughness of his investigations, and especially in the candour of his judgment. The latter quality, indeed, he possessed in so remarkable a degree, that, as a recent writer has remarked, it has become "proverbial." His views, indeed, on questions of *Old* Testament criticism would be regarded in this country as those of the "advanced" school; for on all the disputed points concerning the unity and authorship of the books of the Old Covenant he was led to form conclusions opposed to received opinions. But with respect to the *New* Testament, his position was highly conservative. His defence of the genuineness and authenticity of the gospel of St John is still regarded as the ablest that has yet appeared; and although, on some minor points, his views did not altogether coincide with those of the traditional school, his critical labours on the New Testament must nevertheless be regarded as among the most important contributions to the maintenance of orthodox opinions that the present century has produced. Bleek's works were published partly during his lifetime, and partly after his death. His greatest work, his commentary on the epistle to the Hebrews (*Brief an die Hebräer erläutert durch Einleitung, Uebersetzung, und fortlaufenden Commentar*) appeared in three parts, in 1828, 1836, and 1840 respectively. Of it De Wette said that "It was so distinguished for comprehensive learning and thorough, untiring industry, for so pure and transparent a love of truth and so profound a theological feeling, that it was entitled to one of the foremost, if not the very foremost, place among the exegetical works of our time;" and Delitzsch adds that "every one acquainted with the subject will endorse the judgment." This work was abridged by Bleek for his college lectures, and was published in that condensed form after his death by Pfarrer Windrath in 1868. In 1846 he published his contributions to the criticism of the gospels (*Beiträge zur Evangelien Kritik*, pt. i.), which contained his defence of St John's gospel, and which arose out of a review of Ebrard's *Wissenschaftliche Kritik der Evangelischen Geschichte*.

After his death were published—(1), his *Introduction to the Old Testament* (*Einleitung in das Alte Testament*), 3d edition, by his pupil Prof. Kamphausen, 1869, English translation, by Venables (from 2d edition), 1869; (2), his *Introduction to the New Testament*, 3d edition, Mangold, 1875, English translation, by Urwick, 1869, 1870; (3), his *Exposition of the first three Gospels*, by Holtzmann, 1862; (4), his *Lectures on the Apocalypse*, English translation, 1875. Besides these there has also appeared a small volume containing *Lectures on Colossians, Philemon, and Ephesians*, Berlin, 1865. Bleek also contributed many articles to the *Studien und Kritiken*. For further information as to Bleek's life and writings the reader is referred to Kamphausen's article in the *Darmstadt Allgemeine Kirchen-zeitung*, 1859, No. 20; to the same writer's article in Herzog's *Real-Encyklopædie*, vol. xix.; and to Lichtenstein's *Histoire des Idées Religieuses en Allemagne*, vol. iii.; and to Diestel's *Geschichte des Alten Testamentes*, 1869. (F. C.)

BLEEK, Wilhelm Heinrich Immanuel, son of the preceding, distinguished by his researches in African philology, was born in 1827 at Berlin. He studied first at Bonn and afterwards at Berlin, where his attention was directed towards the philological peculiarities of the South African languages. In his doctor's dissertation (Bonn, 1851), *De nominum generibus linguarum Africæ Australis*, he endeavoured to show that the Hottentot language was of North African descent. In 1854 his health prevented him accompanying Baikie in the expedition to the Niger; but in the following year he accompanied Bishop Colenso to Natal, and was enabled to prosecute his researches into the language and customs of the Kaffres. Towards the close of 1856 he settled at Cape Town, and in 1857 was appointed interpreter by Sir George Grey. In 1859 he was compelled by ill-health to visit Europe, and on his return in the following year he was made librarian of the valuable collection of books presented to the colony by Sir George Grey. In 1869 he visited England, where the value of his services was recognized by a pension from the Civil List. He died at Cape Town on the 17th August 1875. His works, which are of the first importance for African and Australian philology, consist of the *Vocabulary of the Mozambique Language*, Lond., 1856; *Handbook of African, Australian, and Polynesian Philology*, Cape Town and Lond., 3 vols., 1858–63; *Comparative Grammar of the South African Languages*, vol. i., Lond., 1869; *Reynard the Fox in South Africa, or Hottentot Fables and Tales*, Lond., 1864; *Origin of Language*, Lond., 1869.

BLENHEIM (German, BLINDHEIM), a small village of Germany, in the kingdom of Bavaria, and circle of Swabia, situated on the left bank of the Danube, a few miles below Hochstädt. It is only remarkable as the scene of the defeat of the French and Bavarians, on the 13th of August 1704, by the English and the Austrians under the duke of Marlborough and Prince Eugene. Population, 751.

BLENHEIM HOUSE, a princely mansion erected by Parliament for the duke of Marlborough at Woodstock, near Oxford, and, with the manor of Woodstock, settled on the duke and his heirs, in consideration of his military services, and especially his decisive victory at Blenheim. The large sum of £500,000 was voted for the purchase of the manor and the erection of the building, which, notwithstanding the strictures of Swift and the criticisms of Evans and Walpole, is a magnificent pile, built by Sir John Vanbrugh, in a massive Italo-Corinthian style. The front from wing to wing extends to 348 feet; and the great hall is a lofty and noble apartment in good proportions. There are a considerable number of fine pictures in the Blenheim collection, the most noted being "The Young St Augustine and Pope Gregory," by Titian; "Europa," "Esther," and "The Massacre of the Innocents," by P. Veronese; "St Jerome," by Tintoretto; "Magdalen," by C. Dolce; many historical subjects, by Rubens; portraits by him and Vandyck; and "The Woman taken in Adultery," and "Isaac blessing Jacob," by Rembrandt.

BLESSINGTON, MARGARET POWER, COUNTESS OF, novelist and miscellaneous writer, was born near Clonmel, Tipperary, Ireland, September 1, 1790. Her childhood was made unhappy by the bad temper, improvidence, and loose living of her father, and by the reduced circumstances of the family. Her early womanhood was made unhappier still by her compulsory marriage at fifteen to one Captain Farmer, whose drunkenness involved him in debt, and whose debts brought him to the King's Bench prison, where he was killed by a fall in one of his drunken fits, in October 1817. His wife had some time before left his house, and in February 1818 she was married a second time to the earl of Blessington. Celebrated for her wit, her literary accomplishments, her generosity, and her social attractions, she was no less distinguished by her passion for pleasure and her craving for show and a high style of living. In the gratification of these tastes debts were accumulated, and the estates of the earl soon became burdened with "incumbrances." In the autumn of 1822 they set out on a Continental tour, and remained abroad till the death of the earl, which took place at Paris in May 1829. Some years earlier they had become acquainted with Count Alfred d'Orsay, a man of fashion and seeker of pleasure, who was then serving in the army, but quitted it for the sake of joining them. In 1827 he had connected himself with the family by his marriage with the only daughter of the earl by a former wife. After Lord Blessington's death Count d'Orsay, who had separated from his wife, came to England with the countess, and they lived together in London till her death. The home of the beautiful and brilliant countess (first Seamore Place, and afterwards Gore House, Kensington) became a centre of attraction for whatever was distinguished in literature, learning, art, science, and fashion. Ambitious of the distinction of authorship, Lady Blessington had published in 1822 her first work entitled *Sketches*, in two volumes. Ten years later she made herself favourably known by a *Journal of Conversations with Lord Byron*, which appeared first in successive numbers of the *New Monthly Magazine*, and soon afterwards as a separate work. This was followed by a long series of works, most of them novels of high life, several of which obtained considerable popularity. Her *Idler in Italy* and *Idler in France* were rendered temporarily attractive by personal gossip and anecdote, descriptions of nature, and sentiment. Lady Blessington was for some years editor of Heath's *Book of Beauty* and the *Keepsake*, the popular annuals of the day, and also contributed largely to magazines and newspapers. Early in 1849, in consequence of failing resources, the splendours of Gore House were extinguished; its furniture and decorations were sold to pay debts, and its presiding genius withdrew to Paris, whither her friend Count d'Orsay had previously gone. She died there, June 4, 1849. Her *Literary Life and Correspondence*, 3 vols., edited by R. R. Madden, appeared in 1855.

BLICHER, STEEN STEENSEN, Danish lyrical poet and novelist, was born at Vium in Viborg, Jutland, on the 11th October 1782. He was extremely delicate in constitution, and after having passed a year or two at the university, which he joined in 1799, was compelled to give up his studies on account of a consumptive complaint. He accepted a situation as tutor in a family at Falster, and by vigorous physical exercise and flute-playing succeeded in restoring himself to health. He afterwards returned to the university, and completed his course in 1809. Several years were then spent at his father's parsonage, preparing for the ministry and managing the farm. In 1819 he was called to the church of Thorning, and in 1825 to a more remunerative charge at Spentrup. Here he died in 1848. Blicher was first known by his translations of Ossian, but his early poems did not attract much attention. He then contributed to a literary journal, the *Nordlyset*, in which appeared the first of his Jutland tales (*Jydske Romanzer*). The popularity of these romances was surpassed by that of the *National Noveller*, which give an admirable picture of country life in Jutland. His collected poems, some of which had appeared as early as 1814, were published in 2 vols., 1835–36; the novels appeared in 5 vols., 1833–36. A short sketch of his own life and character was prefixed by him to the complete collection,—Old and New Novels (*Gamle og nye Noveller*), 7 vols., 1846–47. Blicher also translated Goldsmith's *Vicar of Wakefield*.

BLIDAH, the chief town of an arrondissement in the province of Algiers in Algeria, about 30 miles inland from the capital, on the railway from that city to Oran. It lies at the base of the Algerian Atlas, in the midst of the fertile plain of Metija, and is beautifully surrounded with orchards and gardens, which afford a pleasant contrast to its ramparts and towers. It has well-built modern streets with frequent arcades, and numbers among its buildings several mosques and churches, a Franco-Arabic and a Protestant school, extensive barracks, and a military hospital. Water is abundantly supplied by an aqueduct fed by the Oued-el-Kebir. As the centre of a flourishing district and a post on one of the main routes in the country it enjoys an extensive traffic, and the inhabitants maintain a thriving trade in oranges, raisins, grain, cotton, and tobacco. The products of the neighbouring copper-mines and of the cork-tree and cedar-groves are also of importance. In the vicinity are the two villages of Joinville and Montpensier, which owe their origin to the military camps established by Marshal Valée in 1838; and on the road to Medeah are the tombs of the Marabut Mohammed-el-Kebir and his two sons. Blidah was a town of some importance under the Turks, but in 1825 it was nearly destroyed by an earthquake. It was not till 1838 that it was finally held by the French, though they had been in possession for a short time eight years before. In 1867 it suffered from another earthquake which also nearly ruined the village of Chiffa. Population in 1872, 8113.

BLIGH, WILLIAM, admiral, was born of a good family in the south of England in 1754. He accompanied Captain

Cook in his second expedition as sailing-master of the "Resolution," and in 1787 was despatched to the Pacific in command of H.M.S. "Bounty," for the purpose of introducing into the West Indies the bread-fruit tree from the South Sea Islands. Bligh sailed, in 1787, from Otaheite, where he had remained about six months; but, when near the Friendly Islands, a mutiny broke out on board the "Bounty," headed by Fletcher Christian, the master's mate, and Bligh, with eighteen others, was set adrift in the launch. This mutiny, which forms the subject of Byron's *Island*, did not arise so much from tyranny on the part of Bligh as from attachments contracted between the seamen and the women of Otaheite. After suffering severely from hunger, thirst, and storms, Bligh and his companions landed at Timor in the East Indies, having performed a voyage of about 4000 miles in an open boat. Bligh returned to England in 1790, and he was soon afterwards appointed to the "Providence," in which he effected the purpose of his former appointment by introducing the bread-fruit tree into the West India Islands. He showed great courage at the mutiny of the Nore in 1797, and in the same year took part in the battle of Camperdown, where Admiral Duncan defeated the Dutch under De Winter. In 1801 he commanded the "Glatton" at the battle of Copenhagen, and received the personal commendations of Nelson. He was subsequently made governor of New South Wales, and vice-admiral of the blue. He died at London in 1817. He was an active, persevering, and courageous officer, although, perhaps, somewhat exacting in his manner.

BLIND. The blind, as a class, are limited to such narrow spheres of action that those unacquainted with the subject fail to realize how large a number of the human race are deprived of sight. In the temperate regions of the globe about 1 in every 1000 of the population is blind, but in less favourable climates the percentage is much greater. When we consider what medical skill has already accomplished in Europe and America, not only for the relief but the positive prevention of blindness, we may readily conclude that in warmer and less civilized countries the class is more numerous and their condition more deplorable.

We rejoice that much can still be done by proper care and treatment to prevent blindness; for instance, ophthalmia of infants is a very common cause, and ought not to terminate in loss of sight, which in most cases results from neglect and dirt. Glaucoma is also a fruitful source of blindness, invariably causing loss of sight if left to itself; but, thanks to Professor Gräfe's brilliant discovery, these cases are generally curable if operated on early. Another very common cause of blindness is serious injury to one eye, which is thus lost, and if the injured organ be not at once removed, sympathetic inflammation and destruction of the other is very apt to follow, resulting in total blindness; whereas, if the injured eye be at once removed the other is generally preserved.

Loss of sight from small-pox is now comparatively rare, owing to the general practice of vaccination, but much undoubtedly may still be done towards diminishing the frequency of blindness by further advances in the art of treating eye disease, and especially by spreading among all classes a knowledge of what has already been done in this direction.

It often occurs that children become blind through the most trivial causes by parents consulting unskilful practitioners. The improvement and increase in the number of well-regulated hospitals now makes it possible for every parent, however poor, to have the best medical advice and attendance.

In all ages of the world the blind have been the objects of pity and commiseration, yet it has only been within the past century that Christian civilization in its grand onward march has taken them in its embrace, and shed the influence of its light upon their midnight darkness. During recent years leading philanthropists have given much earnest thought to the best methods of ameliorating and improving the condition of the blind. Nearly all the European Governments and the States of the American Union have made liberal provision for their education and special training. In Great Britain the work has been left thus far to charitable enterprise. Much, however, has been done,—almost every large town having its asylum, workshop, or home teaching society.

The following summary, from *A Guide to Institutions and Charities for the Blind*, prepared by M. Turner and W. Harris in 1871, will show the state of these institutions at a recent date:—

"In the year 1800 there were only four institutions for the blind in the United Kingdom; during the next thirty years six others were added to the list; in the succeeding thirty years seventeen more were opened; while within the last ten years twenty new ones have been established, making a total now of fifty-three, without including societies for visiting the blind at their homes, and other charities.

Scotland with five institutions sold, in the last year of which we have any report, goods of the value of £21,930, while England with forty institutions only sold in the same period goods of the value of £33,598; and Ireland, only £454.

Scotland provides for, on an average, 76 blind in each institution; while England only provides for 43, and Ireland for 60.

The donations and subscriptions in Scotland for the same year amount to more than £20 per head of the number benefited; while in England they amount to about £21, and in Ireland to about £16.

So far as returns have reached us, it appears that Mr. Moon's system of reading for the blind is adopted by 38 institutions and home-teaching societies, while only 22 use the books of other systems—Lucas's, 7; Roman, 4; Alston's, 4; Frere's, 3; Braille, 4. [Since 1871 the use of Braille has been introduced into many other institutions.]

Of the 30,000 blind in the United Kingdom, there are only about 2250 being instructed or assisted to work. The total amount received per annum for the benefit of the blind, according to the answers received, is about £66,000; besides, there are twelve societies from which no return has been made. Of institutions for the blind generally, we may remark that in each institution nearly the same difficulties appear to exist, the principal one being the difficulty of selling the goods manufactured at such prices as will secure a ready sale and cover the cost of production, and consequently in most instances there is a large surplus stock. In cases where the stock is wholly disposed of, our observations lead us to think that sales have been secured by selling at a loss.

The principal trades practised by the blind in the United Kingdom are the making of baskets, brushes, brooms, mattresses, rugs, mats, caning of chairs, with knitting and sewing for women."

Within a few years a great impetus has been given in England to the higher education of the blind, by the formation of the British and Foreign Blind Association, the establishment of the College for the Blind Sons of Gentlemen at Worcester, and the Royal Normal College and Academy of Music for the Blind, Upper Norwood.

British and Foreign Blind Association.

The first-mentioned association "has been formed for the purpose of promoting the education and employment of the blind, by ascertaining what has been done in these respects in this and other countries, by endeavouring to supply deficiencies where these are found to exist, and by attempting to bring about greater harmony of action between the different existing schools and institutions.

"The founders of the association took as an axiom that in all questions which relate to obtaining impressions by touch the blind are the best judges; the council of the association therefore consists entirely of gentlemen who are either blind, or so nearly so that they have to use the finger instead of the eye for the purpose of reading.

"One main difficulty in the way of educating the young blind is the great cost of most of the appliances; this the council have endeavoured to meet by the manufacture of cheaper and better apparatus than any hitherto in use.

No one who has not made the attempt can have any idea of the extreme difficulty of combining great accuracy and durability with cheapness. This has been in a great measure accomplished as regards the Braille writing frames, which are now within the reach of every blind person who wishes to avail himself of the advantages of writing. The fact that a large number of these frames has been already sold speaks for itself, and, as the great majority of the purchasers are poor, the quick sale is evidence not only of the cheapness of the frames, but also of the widespread desire for self-education existing among the blind.

"Another obstacle to the diffusion of the knowledge of the Braille system has been the absence of printed books in English. With the view of meeting this want one of the council has perfected the process of stereotyping used in France, by which the cost of production of stereotype plates is greatly reduced; and as the blind can themselves produce these plates, a new and remunerative means of employment has been discovered. Some school books have already been issued by the association, and will shortly be followed by others. The work on the *Education and Employment of the Blind*, by the honorary secretary, has been published under the sanction and at the expense of the association."

Different types for the Blind. The following extract from an address delivered by the honorary secretary before the Society of Arts on the various types for the blind, shows how thoroughly they are investigating the subject:—

"The happy idea of printing on paper letters recognizable by the touch is due to M. Hauy of Paris, who printed his first book in 1784, and founded the Institut des Jeunes Aveugles, Paris. The type he adopted was the script, or Italic form of the Roman letter. This was introduced into England by the present Sir C. Lowther, who printed the gospel of St Matthew in 1832 with type obtained from Paris, and followed it with other portions of the Bible. In 1827, Gall, of Edinburgh, printed the gospel of St John in Roman capitals, in which, however, all curves were replaced by angular lines, and the lines themselves were serrated, which changes, he believed, gave greater distinctness to the letter.

Alston, of Glasgow, adopted Fry's plan of using ordinary Roman capitals. Dr Howe, of Boston, U.S., makes use of the small Roman letters, giving them angularity according to Gall's idea.

The Philadelphia type does not differ much from Alston's. The combination of capitals with small letters has also been tried, and a society has recently been formed at Worcester with the intention of printing on a large scale in this type. In Germany various modifications of the Roman letter exist, the principal of which, the so-called Stachelschrift of Stuttgart, consists of Roman capitals formed by finely dotted lines. All these modifications are suggestive of the strong tendency among those who have attempted to benefit the blind to retain for them the form of letter to which the seeing are accustomed, while the constant change of form indicates a fact with which most blind persons are familiar from personal experience, viz., that none of these modifications are satisfactory as to the primary condition of being easily felt. A better form than any which has obtained currency was suggested twenty years ago by Mr Welch, a blind man, who has been the pioneer of education amongst the blind of London, and this is almost identical with one independently worked out by Mr Littledale of Cheltenham.

The second great class is made up of alphabets deviating more or less widely from the Roman letter, and consists of a stenographic shorthand invented by Mr Lucas, a phonetic shorthand due to Mr Frere, and a full written system introduced by Mr Moon, in which the Roman letter is retained in a more or less modified form whenever he considered this could be done compatibly with easy recognition, the simple line-signs employed by Mr Frere being used to replace the more complicated of the Roman letters. It will be necessary to examine these systems in detail, and it will facilitate this examination if we compare them with each other in the following particulars:—(*a.*) As respects the shape of the letter; (*b.*) As respects the advantage of conformity with the Roman letter; (*c.*) As regards the reading from right to left and from left to right alternately; (*d.*) Advantage of a shorthand as contrasted with a full written system.

(*a.*) *As respects the shape of the letter.*—Mr Lucas and Mr Frere brought out their systems about the year 1838, Lucas preceding Frere by a few months. They employed at first almost identically the same characters, but unfortunately could not agree to represent the same sound by the same symbol. Mr Frere had the advantage of having his plan carried out by a very ingenious and sensible blind man, who soon discovered that the letters formed by lines and curves upon which dots were placed were too similar to those formed by the corresponding lines and curves without dots; he, therefore, changed all his dotted characters, replacing the dotted curves by angles of 45°, and the dotted lines by lines in which a short line is substituted for the dot.

The result of this change is, that Frere's character is now far superior to Lucas's in the quality of easy recognition. Mr Moon's character, in the large size which is used by him, is quite as easily distinguishable as Frere's, but in the form in which he now prints his characters, his right-angles are not true right-angles, but are rounded. In the size which he uses, this defect is of very little importance, but it effectually prevents any considerable diminution, because, if this is attempted, the rounded right-angles cannot be distinguished from the hooked lines.

The importance of using a character as small as is compatible with easy recognition may be readily understood from the following statement:—The largest type used by Mr Frere is that employed in the gospel of St John. The character is 4½-sixteenths of an inch long, and is about the same size as Moon's character. The pages occupied by the gospel of St John in Frere are 96. In his medium type, in which the length of the letter is 4-sixteenths of an inch, the same matter would go into 67 pages; and in his smallest type, in which the length of the letter is 3½-sixteenths, it would occupy 46 and a third pages. It has been found, by an experience extending over 27 years, and embracing many hundreds of individuals of all ages and conditions, that all those who can read the largest type can read the medium, and almost all can read the smallest.

The medium type is very generally preferred, as being more pleasant to the finger, and many with delicate touch prefer the smallest for the same reason. Thus it will be seen that, by selecting a well-devised character, not only can a very considerable saving be made in the size, and therefore in the cost of books, but by a diminution of size, within certain limits, the character is rendered absolutely more legible. The gospel of St John, in Moon's type, occupies 140 pages.

(*b.*) *As respects the advantage of conformity with the Roman letter.*—Much has been said and written on this subject. A favourite argument with the advocate of the Roman letter is, that by its use a blind man can be assisted in his reading by those around him who are possessed of sight. This, no doubt, would be valid if no simpler character for the blind had been invented, but when we have to choose between a character in the reading of which the blind can be assisted by the seeing, and one which is so simple that no assistance is required, there can hardly be a doubt as to which ought to be used.

Another plea for the use of the Roman letter is, that by its means the blind can write in a character understood by everybody. This writing is, as we shall presently see, a very imperfect process; but this argument is undoubtedly of some weight. These remarks apply simply to the existing systems in which the Roman letter is employed. It is probable that a much more legible alphabet might be constructed, but, after our 96 years of experience and experiments with the Roman letter, another failure may well be feared. The small angularized Roman letter of Dr Howe, of Boston, which is used in most of the schools of the United States, is probably as good a form as any, and if printed in a larger size would not be difficult to feel; in its present size, however, it is far too small, and has signally failed in America. The American schools are all State institutions, and have to furnish accounts to their respective State Legislatures of the work done by them.

Out of 664 pupils in seven schools, where the Roman character of Dr Howe is used, one-third learn to read fluently, one-third by spelling, while none fail; and it must be borne in mind that those who learn to read by this system also acquire an admirable method of writing. Moon's system retains those Roman letters which can be easily distinguished, and thus makes a transition between the systems in which the Roman character is used and those which employ purely arbitrary signs. For this reason, and from its great simplicity of construction, it is more easily learned than any other, and therefore is well suited to the great mass of the poor, who from want of intelligence or of application cannot learn one of the shorthand systems. Its great bulk, however, involving costliness of production and comparative slowness of reading, is a serious obstacle to its general use.

(*c.*) *Reading from left to right, and from right to left, alternately.*—In Frere's system the lines are read from left to right, and from right to left, alternately, an arc of a circle taking the finger from the end of the upper to the beginning of the lower line. The plan may be illustrated by imagining the letters to be fixed on the upper edge of a long string. Let it be supposed that this string is doubled backwards and forwards upon itself in such a way that the letters always occupy its upper edge. This will give a good idea of Frere's method of reversing the line; not only is the line reversed, but every letter in it is also reversed, so that the finger, when

moving forwards, whether towards the right or towards the left, meets the characters in the same position, and is, in fact, never moving backwards, in the same manner that a person may walk to the end of a room, turn and walk back, yet is moving forwards in both directions. Moon, on the other hand, while borrowing the reversal of the line from Frere retains the letters in the returning line in the same position as the advancing, so that the finger in the return line meets the characters in the opposite direction from that in the advancing line; and to those accustomed to Frere's simpler method of reversal an unpleasant feeling is produced, exactly comparable to walking backwards.

The following example of both modes of reversal, in which Roman capitals are used, will make this clear:—

Frere's Method.

I WILL MAKE DARKNESS
LIGHT BEFORE THEM

Moon's Method.

I WILL MAKE DARKNESS
.MEHT EROFEB THGIL

No doubt habit will accustom a reader to either plan, and probably there is not much difference in the difficulty of either, but, as we shall see by-and-by, it is absolutely necessary for writing that the pupil should thoroughly understand that, whichever way he goes, he is moving forwards; it is, therefore, wise to accustom him in reading to a process which he will have to follow in writing. Opinions differ widely among the blind whether it is best to read forwards in one direction and backwards in the other, or forward in both; it seems, however, among those who have had experience of the return line, that there can be no doubt of its great value, as by its use no time is lost by the reading finger having to return from the end of the upper to the beginning of the lower line, and the setting free of the left hand enables it to follow the right in reading, to take its place, or to rest.

(*d.*) *Shorthand.*—By a shorthand system, reading is more rapid, and a nearer approach is made to the way in which the eye takes in a whole word at a glance, than in a full-written system. The books are also more manageable and less costly, but the stereographic method is distinctive of correct spelling, and in the phonetic method this is not even attempted; yet it is advisable, for many reasons, that the blind should be able to spell. The shorthand systems seem therefore to be of the same use to the blind as to the seeing—not being of universal application, but extremely useful to those who have to read much.

In all the systems which we have hitherto considered, the letters, whether Roman or arbitrary, are formed by raised lines. The method employed for writing them is as follows:—Small cubes of wood are used with projecting pin points, so placed as to assume the form of each letter. The paper to be written on being laid on a soft surface, the pin-point letters are pressed into it; each point carries some of the paper before it, forming a little prominence on the reverse side, and as the pin points are very close together, the series of little prominences formed by them feel to the fingers like serrated lines. This plan ought rather to be called printing than writing. It requires great practice, and is at the best very slow and imperfect; yet it has its uses, as by employing Roman capitals the blind can correspond with the seeing. The letters, however, are not sufficiently distinct, and communications from blind correspondents written in this manner, or with pencil, are less satisfactory, both to writer and reader, than if the letter had been written from dictation. Printing from the Roman letter (not embossed) can be effected by the blind, with considerable rapidity, by means of Hughes's typograph or Foucault's writing-machine; but the blind writer cannot read what he has written, and the apparatus is so costly that it is not procurable by the poor.

[A new machine called the 'type-writer,' has lately been invented in America. It is largely manufactured, and is coming into general use for the seeing. It is equally well adapted to the use of the blind, is very simple, and can be manipulated very rapidly. A skilful operator can write at least twice as fast as an expert penman. It is not only a valuable invention, but one superior to all others of the kind.]

Various plans exist to enable the blind to keep their lines when writing with a pencil or with a stile on carbonized paper, but such writing can only be used for correspondence with the seeing, and cannot, of course, be read by touch.

We come now to the third class of systems, viz., those in which the letters are formed by a combination of dots. These are:—

1. The Braille system, universal in France, both for writing and printing, and very much used for both purposes in Switzerland, and employed as the *written* character in almost all countries, with the exception of the United Kingdom.

2. The Carton type, which was introduced into Belgium by the Abbé Carton.

3. Hughes's system consists of large and small dots, and lines placed in different positions. It never obtained much currency, and seems never to have attracted the attention which its ingenuity merited.

4. A modification of the French method has been lately proposed in New York, and seems to have much to recommend it.

To begin with the French method. This was invented in 1834 by M. Braille, a blind pupil of the *Institut des jeunes Aveugles.* It spread with great rapidity, and has, as we have before seen, become almost the universal written language of the blind. Its signs are purely arbitrary and consist of varying combinations of six dots placed in an oblong, of which the vertical side contains three and the horizontal two dots. For writing, a frame is used consisting of a grooved metal bed, containing ten grooves to the inch; over this is fitted a guide whose vertical diameter is $\frac{3}{10}$ inch, while the horizontal diameter is $\frac{2}{10}$. This perforated guide is fixed into a light wooden frame, like the frame of a slate, which is attached to the grooved metal bed by hinges. The paper is introduced between the frame and the grooved bed. The instrument for writing is a blunt awl, which carries a little cap of paper before it into the grooves of the bed, thereby producing a series of little pits on the side next the writer. When taken out and turned over, little prominences are felt, corresponding to the pits on the other side. The reading is performed from left to right, consequently the writing is from right to left; but this reversal presents no practical difficulty as soon as the pupil has caught the idea that in reading and writing alike he has to go *forwards.* The brass guide has a double row of openings, which enables the writer to write two lines; when these are written, he shifts his guide downwards until two little pins, which project from the under surface at its ends, drop into corresponding holes of the frame, when the writer writes two more lines, and this operation is repeated until he arrives at the bottom of the page.

The first ten letters, from 'a' to 'j,' are formed in the upper and middle grooves; the next ten, from 'k' to 't,' are formed by adding one lower dot behind to each letter of the first series; the third row, from 'u' to 'ù,' is formed from the first by adding two lower dots to each letter; the fourth row, from 'â' to 'w,' similarly, by adding one lower front dot.

The first ten letters, when preceded by the prefix for numbers, stand for the nine numbers and the cypher. The same signs, written in the lower and middle grooves, instead of the upper and middle, serve for punctuation. The seven last letters of each series stand for the seven musical notes—the first series representing quavers, the second minims, the third semibreves, the fourth crotchets. Rests, accidentals, and every other sign used in music, can be readily and clearly expressed, without having recourse to the staff of five lines which forms the basis of ordinary musical notation, and which, though it has been reproduced for the blind, can only be considered as serving to give them an idea of the method employed by the seeing, and cannot, of course, be written. By means of this dotted system a blind man is able to keep memoranda or accounts, write his own music, emboss his own books from dictation, and carry on correspondence.

But this French system, though extremely useful, is not perfect. The letter is too small for ready recognition by the unskilful or hard-handed, and if this is sought to be remedied by increasing the size, the reading finger does not cover the whole of the letter, and has to proceed up and down, feeling out each letter, instead of following the even gliding motion essential to good reading. The modification proposed in New York remedies this defect, though this does not appear to have been the intention of its promoters. It proceeds on the principle that the letters occurring most frequently in the English language should be represented by the fewest number of dots, and that the letters should be so spaced that a letter composed of one dot should not, as is the case in the French system, occupy the same room as one with six dots. For this purpose the oblong, consisting of six dots, composing the root-form of the letter, is placed horizontally instead of vertically, the greatest vertical depth of any letter in two dots instead of three. From these two changes results a saving of about one-third in space; this involves a saving of about one-third in the price of printed books; writing is rendered more rapid; and as the size can now be increased, owing to the diminution of the vertical length of the letter, it can be made sufficient for the dullest touch. Ten-word and part-word signs have been introduced, which effect a further saving of nearly one-third, while they do not interfere in the least degree with correct spelling. These advantages make it well worth while to consider whether the modification of the Braille system ought not to be adopted as the written system of all English-speaking blind; but before such a step is recommended, the question should be carefully considered in all its bearings on musical notation as well as on ordinary writing."

Worcester College.

Regarding the Worcester College for Blind Sons of Gentlemen, founded in 1866 by the Rev. R. H. Blair, the Report informs us that—

"It was opened with the view of giving to families of the better class an opportunity of educating their children in a systematic

manner, with a due regard to home comforts, and with surroundings befitting their position.

The course of education projected by Mr Blair was such as would convert the pupils into intelligent home companions, if no other object were desired. But a conviction, based on personal knowledge, that the blind were capable of the highest competition with the seeing, lay at the root of this gentleman's endeavours. Self-helpfulness and usefulness in the ordinary affairs of life is therefore but one of the first results which reward the teaching of the blind; and it appears that blind men can be made reproductive also, not only in the particular instance, but in the bulk, and that the arts of teaching and lecturing, acting as deputations, translating, presiding over blind or other institutions, the law, and in the most favoured cases the church, are fully within the capacity of the well-educated blind. A prejudice has hitherto existed against the employment of blind men, owing to their supposed incapacity, and certain other drawbacks resulting from neglect. Let this impression be removed, and there will be an increase in the number of positions open to them.

For an entrance into these walks of life, the training must be such as to enable its recipients to compete for university distinctions. The objections to this course, if they are entertained, will be removed by a little reflection on the nature and uses of a university; and the difficulties which in the idea of inexperienced persons a blind man has to overcome, are greatly diminished by being met and grappled with in early years, and are actually being materially lessened by the earnest efforts now made by blind instructors and investigators.

It is impossible to rule definitely at what age the school education of a child born blind should begin. Children vary as much in natural quickness as parents in the power of educating. A quick and resolute child will, through the clumsiness of nurses or the carelessness of a parent, early acquire tricks which it takes years to eradicate, and acquire habits and ways of thought and action which may have a profound effect on his after life. The sooner, therefore, a child can consistently with his health and other considerations be admitted to cheerful and active society, where his character can have free play and find sympathy, yet be quietly trained, the more easy will his education be afterwards. For those who have become blind from accident or disease, in childhood or towards the age of adolescence, one word of advice may be given. As soon as it is ascertained that the blindness is past remedy, the child should be sent to school, so that the habit of study may be remitted as little as possible. It is in the highest degree impolitic to allow the faculties to degenerate through several years' disuse, as is often done; and it is in reality kinder to a child or youth to send him away to pick up strength and consolation by the example of his cheerful and patient fellows, and to distract his grief by learning the instruments which he will ultimately need in his education, than to keep him in the indulgences of home, brooding over his misfortune, or buoyed up by a hope which will not be realized.

No claim to exclusiveness is asserted in the use of English types. There are useful works to be found in all; and when a pupil arrives who has been educated in one or other form of type, he is never discouraged from its continued use. But as uniformity of class-books is desirable, and one system must be employed as a basis, the Roman form, in which are printed books suitable for higher education, is adopted for class purposes. Dr Moon's type is read by some for recreation or private study, and the American Bible, which is the most portable yet printed, and is beautifully executed, is read by those whose dexterity, acquired by long practice, enables them to master this somewhat difficult, because small, type. After some years of practice the desire for smaller type seems to become a passion for those possessed of a quick and nimble touch.

Dr Moon's type is large and easy, and comprises the Bible, Prayer Book, and a large number of religious and devotional works, together with numerous stories, biographies, and other works suitable for the young and aged. Dr Moon has also several educational works of a very useful character; but his plan of action has not yet led him to enter largely into the production of higher literature."

Royal Normal College. The Royal Normal College and Academy of Music for the Blind has for its object the affording of a thorough general and musical education to the youthful blind of both sexes who possess the requisite talent, so as to qualify them for self-maintenance. The Report of the institution states that

"As without previous trial it would in many cases be difficult to determine whether an applicant for admission has sufficient capacity for the kind of education given at the college, candidates will first be received as *probationers* for a term of three months, or less. If, at the end of that period, they are found to possess adequate ability, they may become permanent pupils.

With a view to adapting the methods of instruction to pupils of different ages and capacities, the following classification has been adopted, viz.:—A. The elementary section, the instruction in which is designed especially for children from seven to nine years of age; B. The intermediate, for pupils from nine to twelve years of age; C. The junior, for pupils from twelve to fifteen years of age; D. The senior, for pupils from fifteen to twenty-one years of age. Exceptional cases over twenty one years of age can only be admitted by special vote of the committee.

The college embraces three distinct departments—1. General education; 2. The science and practice of music; 3. Pianoforte tuning.

The department of general education embraces all the ordinary branches of a sound English education. Special care is bestowed on the intellectual training of the pupils; for experience has shown that in order to qualify the blind for self-support, it is essential to afford them a thorough *general* as well as musical education.

In the musical department both vocal and instrumental instruction is given, according to the improved methods which have been employed during late years with marked success in the leading institutions of France and America. This department embraces the culture of the voice, the study of the piano, organ, and other solo instruments, harmony, counterpoint, composition, the history of music, and the art of teaching.

In the department for training the pupils in the art of regulating and tuning pianos, pupils are instructed who have passed the age at which they might have become qualified for remunerative employment in other departments. Though a superficial knowledge of the art of tuning may be readily acquired by those deprived of sight, a prolonged course of careful training is necessary in order to enable them to become thoroughly successful.

Experience has shown that the blind can seldom fully support themselves merely by *manual labour*, and the great majority of those who have been trained to industrial trades continue to require charitable assistance during their whole life.

It is well known that many of the blind possess musical talent, yet only a small number in the United Kingdom have ever been qualified to earn their living by the profession of music.

Such was formerly the case in other countries, but during recent years great improvements in the general and musical education of the blind have been effected abroad, particularly in France and America, and large numbers of this class educated in the institutions of those countries have been enabled to maintain themselves fully by various pursuits, especially as skilled organists, teachers, pianists, and pianoforte tuners.

In view of the practical results of the improved education of the blind in other countries, the Normal College and Academy of Music was founded in order to afford similar advantages to the youthful blind of the United Kingdom.

The college was opened in March 1872, under the direction of a committee, including members of the governing bodies of various metropolitan societies and institutions for the blind, with an experienced principal, and a staff of highly-trained teachers.

Upwards of seventy pupils from London and other large towns have been under instruction; a number have already left the college, and are now regularly employed as thoroughly competent pianoforte tuners."

As it will be impossible in this article to give any lengthened account of the institutions on the Continent and in America, we will briefly sketch the plan of working in a few of the most progressive.

The following extracts from addresses delivered at the First European Congress of Teachers of the Blind at Vienna in 1873, will best give an insight into the schools of Saxony:—

Saxony. Herr Reimer, superintendent of the *Preparatory School for the Blind* at Hubertusberg, pointed out that, "even among the families which are not very poor, blind children often grow up without learning to wash or feed themselves, with hands hanging soft and helpless at their sides, and thus become more incapable than the poorest, who are forced to exert themselves by the necessity of the case.

If they are not taught to help themselves at home, it is very difficult to teach them at school, and as the existing blind institutions cannot admit young children without injuring the education of the older ones, they ought to be taught in preparatory schools or Kindergärten separately, which should be established by the State.

In the preparatory school at Hubertusberg in Saxony, the first thing aimed at is the strengthening of the limbs, then to make the children use them properly, to make them help themselves instead of relying on others, to correct their bad habits and to improve their mental condition, arousing in their minds the love of God and of truth as well as conscience. All this must be done methodically, and each lesson must be given separately and repeatedly as well as most patiently.

The change wrought thus is wonderful, if the teachers are experienced. They must be encouraged to move about as directed, and the 'Fröbel play and exercises' will be found useful. Plaiting

strips of leather, and other occupations which combine play with work, are carried on with advantage. A good manager of Kindergarten can do them great good, and gymnastics give them the power of controlling their limbs; but every exercise must be first taught singly.

Object lessons must be given by means of models, stuffed animals, birds, fish, &c., to bring out the powers of memory and reason. Simple hymns and ballads are practised.

Very little technical work can be taught, except making rush baskets, &c., as the children are all under ten. This school has been carried on for eleven years, and the benefits of teaching blind children so early are plainly seen by all who watch the progress which they make when removed to the Blind Institution; they are fit for independent work at an age three years less than the average of those who do not go through it.

As the children pass through the institution more rapidly, there is also more room for those who become blind as adults."

Of the *National Blind Institution* at Dresden, Dr Reinhard, the director, said—"It is organized so that the working school forms an essential part of it, and when children enter it, consideration is at once given, not only to their physical, religious, and intellectual education, but also to their instruction in work. Whilst between the ages of six and eleven they remain in the preparatory school, and find inexhaustible occupation in Frobel's system of play and exercise.

'Playwork' is given them as they become fit for it; for the feeling that they can make something useful rejoices the little workers and excites their activity; it is important that they should learn early to aim at real work. They learn to plait reed mats, which is an excellent means of strengthening the muscles of the arm and hand, and they also make little rush baskets.

The range of their work is extended when they are transferred to the higher class, which is usually during their eleventh year; and from that time till their confirmation, which is generally at the end of their fourteenth year, they have at least three hours' work every day in the shops.

The work of the girls is, unfortunately, much restricted, and it is doubtful whether their learning to make baskets and rope is without injury to their constitution. Besides, we must not lose sight of the evils arising from their working with male overseers and workmen.

Hence, girls learn in general only knitting, plaiting counterpanes, chair-caning, hair-working, and sewing—as much as is required for mending their linen.

Hair-work has already been adopted in another institution, and is the most profitable work for blind girls, as a clever one can earn 7 or 8 groschen (about 9d.) a day by it, whilst the quickest knitter can scarcely make 2 groschen a day.

The boys learn either basket-making or rope-making; they learn in the rope factory various kinds of light work, and, when they have been confirmed, choose for themselves between those two trades, their muscles being strengthened by alternately being employed at both.

It is important to consider the grounds of fitness for these trades. Rope-making requires strength and health of body, for much of the work must be carried on in places exposed to the weather; and besides this it requires a great deal of dexterity which is not indispensable in basket-making. It is also of great importance that each should learn the trade in which he is most likely to succeed after leaving the institution; for the great object is that pupils should be fitted for independent work eventually.

All those who understand the subject are now convinced that the blind cannot be really helped by building asylums. If there were three times as many asylums as there are schools, there would not be room for all, and the inmates would never be satisfied with their condition. Even women prefer an independent life full of care to the sameness of an asylum, where one quarrelsome person often embitters the whole life of the institution.

If there is any possibility of establishing pupils of either sex without exposing them to the risk of losing their health, there can be no doubt that it is to be preferred to placing them in asylums.

"The Dresden Blind Institution is managed on the principle that the pupils, on commencing independent work, require much assistance before they can support themselves by it, and that the institution must give the necessary help. The director of the institution makes known to the manufacturers that a blind worker is coming to settle near them, and induces some of the families around to take an interest in him, and recommend him for employment. He also inserts in the newspapers short notices describing his capacity for work, and his difficulty in finding customers, &c., and requesting people to employ him.

The outfit required for pupils on leaving the institution consists of tools and clothing, and materials must also be provided at first. The cost of these is partly defrayed by the fund established for the purpose, partly by the savings of the pupils, and partly, if necessary, by a grant from the parish.

It is indispensable that the blind worker should have some person near in whom he can fully confide, and from whom he can get advice and help in any time of temporary difficulty, whilst the manager of the institution can rely on his taking an interest in the worker, and seeing that he obeys the rules.

The purchase of raw material causes the greatest difficulty; the blind man has not the means of buying much at a time, and must, consequently, pay highly for it; therefore the institution helps him by buying it at wholesale prices and letting him have it at the same price in small quantities. The number of his applications for materials shows the managers whether the man is industrious.

More than 200 blind support themselves in Saxony by means of the aid afforded by the fund and their own exertions. The fund amounted, in 1873, to 85,000 dollars, subscribed in all parts of the country."

Previous to the Franco-German War, Mr. Liebreich, a celebrated oculist and practical friend of the blind, by order of the empress of the French, prepared a report in regard to the *Institution Impériale des jeunes Aveugles* of Paris, in which he says that the institution— **Paris.**

"Is an establishment of the State, in which children of both sexes deprived of sight receive an intellectual, musical, and industrial training. Children are received at the age of 13 years. They remain in the institution 8 years, and are made professors, musicians, tuners of pianos, workmen and workwomen.

During the last ten years 110 male pupils have left the institution, concerning whom we have received satisfactory information. The workwomen, on the contrary, earn but very little; among 166 blind, 108 have received a very good education, which ensures to them an easy and independent living; 56 have received an elementary training, and have not been put entirely beyond the charge of public charity.

The annual expense for 200 pupils is very nearly 240,000 francs (of which 146,000 francs are given by the State), making an average of 1200 fr. (£48) per pupil,—the workman costing a little less, the artist a little more. This sum is not excessive for the education of a tuner, a professor, or an organist, but it certainly is for the education of a workman, who only receives an elementary training, and is not even qualified to earn his own living.

M. Gaudet, chief instructor of the institution, expresses disapproval of the simultaneous education of artists and workmen. He says, 'Realising from the first the great difference which exists between the future of an organist or a piano tuner on one side, and of a blind workman on the other, the apprentices regard themselves as sacrificed; therefore they do all they can to become tuners, and thus often lose much time in fruitless efforts before they resign themselves to become workmen, and even then toil reluctantly. On quitting the establishment to follow their occupations, they are not habituated to assiduous toil; returning to their indigent families they regret the comfortable life of the institution, and finally become discouraged.'

Tuners begin ordinarily to work with piano manufacturers, and earn easily 1500 francs per year. If a little later they succeed in obtaining a town connection, they have no difficulty in earning double that or more. Some have even succeeded in uniting manufacture with tuning. The organists, by obtaining places in churches and by giving music lessons, very soon earn a good livelihood.

In short, the tuners, organists, and teachers have, in spite of their infirmity, become independent men, exercising honourable and lucrative professions; some have married and reared families, others have come to the aid of their indigent relatives.

Very different is the lot of the blind workmen, who by toiling without relaxation many more hours than sighted workmen, barely succeed in gaining a part of what they need to support themselves. By perfecting as far as possible the industrial training of the institution, a greater number of the male pupils might be enabled to earn 300 or 400 francs, but none far exceed this sum. The workwomen seldom earn more than 100 or 150 francs per year."

The institutions of America are not asylums, but in the truest sense of the word educational establishments, in which the blind, without regard to their future, receive a thorough education. The blind in the United States are socially far above those of any other country; large numbers of them become eminent scholars and musicians, and even their blind workmen enjoy a degree of comfort unknown in England or on the Continent. **America.**

The results achieved by the Perkins Institution at Boston, U.S., are particularly instructive. High-class musical training appears to have been commenced there about 13 years ago, previous to which time the results in this respect were far from being satisfactory. The report of 1867 states that music is now taught to all of both sexes whose natural abilities make it probable that under proper

instruction, they will succeed as organists, teachers of music, or piano tuners, and goes on to say—"The teaching of music and playing is now the largest single field open to the blind as a means of support, and it seems to be growing larger. People are becoming more disposed to employ them; and as they go forth from the school they have more and more ground of hope that they will find opportunities to earn their living in this way." The whole tone of mind among the musical pupils has been changed, for instead of looking forward to the future with fear and anxiety, they now feel a well-grounded confidence in themselves. It seems that in Boston, and in America generally, the blind are able to earn more as teachers of music than as tuners, which is exactly the reverse of the state of things existing in Paris, and may arise either from differences in the condition of the two countries, or from the training for teachers being more thorough at Boston than at Paris; but their experience is identical in one respect, which is, that the blind who have the requisite amount of talent are almost certain to make a good income out of music; but to attain this end they must aim high. It will not do to be equal to the average seeing teacher or tuner; they must be superior; and this involves a good musical notation with first-rate masters, instruments, and appliances, and above all, a determination on the part of managers and teachers to overcome all obstacles.

A few paragraphs from American reports will sufficiently illustrate the enlightened views held in that country in regard to the education of the blind.

"A school for the higher education of the blind should be specially adapted to the condition and wants of the persons to be trained. In it the course of study should be the same as in our best colleges. All instruction should be oral, and the apparatus and modes of illustration be addressed to the touch. It should be supplied with text-books, maps, diagrams, and the like, in raised characters. It should have large collections of models of various kinds, such as weights, measures, tools, machinery, and the like; mannikins and models showing the anatomy of plants and animals, as well as their outward form. It should have collections of shells, crystals, minerals, and the like; models and sections showing geological strata; philosophical apparatus adapted to the touch; in short, everything that can be represented by tangible forms

It would amaze those who have not reflected upon it to know how much can be done in this way. Saunderson, the blind professor of mathematics in Cambridge, not only knew ordinary money well, but he was an expert numismatist, and could detect counterfeits in a collection of antique coins better than ordinary persons could do by the sight.

Such an institute should have able professors and teachers, with special aptness for adapting their lessons to the condition of their scholars. It should furnish special facilities for the study of languages, ancient and modern, of mathematics, of pedagogy, and especially of music. It should also be well provided with everything necessary in a good conservatory of music, and have funds for the payment of competent teachers.

It is evident that there are a large number of persons to whom such an institute would be a source of great happiness, and a means of preparation for great usefulness.

A little reflection will show what a great advantage generous culture would be to a blind man, even if he were to be only a musician. Let him be ever so accomplished in his immediate art, he is under great disadvantages as compared with his competitors who can see. But if he has generous culture in other branches of knowledge, he will have advantages which few of them possess, and of course he will be more nearly on a level with them, and more capable of earning a living and enjoying it. Human effort will in such a case be successful in counteracting the principal evil which flows from the infirmity of blindness."

"The careful observer will see a marked difference between a hundred youths in a blind institution and the same number of boys in an ordinary school. This is especially true of the male sex. He will find among the blind a larger proportion of scrofulous, narrow-chested, angular, pallid, and feeble boys, who move sluggishly and soon tire; and a smaller proportion of those full-chested, chubby, rosy, elastic creatures, whom nothing can keep still, and nothing tire out

Now, if the blind, as a class, have a much smaller *quantum* of life than ordinary persons, it must be either on account of some flaw in the stock whence they sprung, or of some peculiarity in their mode of life, induced by their infirmity, such as bodily inactivity; but it probably results from both causes. At any rate, it is a matter worth considering.

Vitality of the Blind.

The following tables have been calculated from data furnished by *seven* American State Institutions for the Blind namely, those of New York, Ohio, Pennsylvania, Illinois, Missouri, Tennessee, and Massachusetts, and are the results of careful discussion of data, by far the most extensive and trustworthy, it is believed, yet published in any country.

In each of these tables the number of the blind actually surviving in 1859 are compared with the numbers that *should* then be surviving, according to two different Life Tables—first, the Massachusetts Life Table, prepared by Mr Elliott, from the State Census and Registration Returns for the year 1855; and secondly, the English Life Table, prepared by Dr Farr of London, from the returns for the year 1841: –

TABLE I.—*Comparing the relative vitality* (*or ability to resist destructive influences*) *of the Blind, at divers ages of life, according to the combined experience of seven American State Institutions for the Blind, with that of the populations of Massachusetts and of England respectively. Calculated by Mr E. B. Elliott, Consulting Actuary, Boston.*

Ages on Admission.	Number of Persons Admitted (known whether Surviving or Deceased).	Average Age on Admission.	Average Years elapsed, to middle of 1859.	Number Deceased (before the end of 1859).	Number Surviving (in 1859).	According to Elliott's Massachusetts Life Table. Number that should be Surviving (in 1859)	Deficiency of Actual Survivors, relative to the Number that should be Surviving. Number.	Per cent.	According to Farr's English Life Table. Number that should be Surviving (in 1859).	Deficiency of Actual Survivors, relative to the Number that should be Surviving. Number.	Per cent.
0–6	14	4·4	19·1	1	13	12·0	1·0[2]	...	12·0	1·0[2]	...
6–10	210	7·7	14·3	39	171	189·2	18·2	9·6	189·8	18·8	9·9

14–18	209	15·5	13·3	38	171	182·0	11·0	6·1	186·6	15·6	8·4
18–22	177	19·3	14·8	50	127	149·6	22·6	15·1	154·0	27·0	17·5
22–26	101	23·3	14·6	19	82	84·8	2·[illegible]	3·4	86·9	4·9	5·6
26–30	47	27·4	12·6	10	37	40·3	3·[illegible]	8·1	40·8	3·8	9·4
30 and over	38	37·2	12·7	11	27	31·9	4·9	15·4	31·8	4·8	15·2
Age not specified	19	...	12·4	4	15	16·7[1]	1·7	10·4	17·1[1]	2·1	12·4
All ages...	1102	15·4	13·8	224	878	963·7	85·7	8·9	978·5	100·5	10·3

Note.—This table may be read thus:—Between the ages of 6 and 10 the number of persons admitted to the above-mentioned institutions, of whom it is known whether they were living in 1859 or had previously deceased, was 210; their average age on admission was 7·7 years: the average period elapsed since admission, and previous to the middle of the year 1859, was 14·3 years; the number of those who died before the end of the year 1859 was 39,—the number surviving in 1859 being 171. The number that should be surviving, according to the *Massachusetts* Life Table, is 189·2. Hence the number of actual survivors was 18·2 *less* than the number demanded by the Massachusetts Table, which deficiency is 9·6 per cent. of (189·2) the number so demanded. The number that should be surviving, according to the *English* Life Table, is 189·8. Hence the number of actual survivors was 18·8 *less* than the number demanded by the English Table, which deficiency is 9·9 per cent of (189·8) the number so demanded.

[1] Calculated on the assumption that the average age on admission of the persons whose ages were not specified was the same as the average age of those whose ages were specified, to wit, 15·4 years.

[2] Excess.

TABLE II.—*Comparing the relative vitality (or ability to resist destructive influences) of the Blind, at different periods after admission, according to the combined experience of seven American State Institutions for the Blind, with that of the population of Massachusetts and England respectively. Calculated by Mr E. B. Elliott, Consulting Actuary, Boston.*

Years	Number of Persons Admitted (known as Surviving or Deceased)	Number Deceased (previous to the middle of 1859).	Number Surviving in 1859. 1858	23	0	23	18·0	1	22·8	0·2[1]			22·8	0 2[1]		
1859	40	0	40	16·2	0	40·0	0·0			40·0	0·0		

Note.—This table may be read thus:—Of the 68 persons admitted to the before-mentioned institutions during the year 1844, 14 died previous to the middle of the year 1859, and 54 were surviving in that year. The average age on admission of the 68 persons was 13·9 years, and the average number of years elapsed between the time of admission and the middle of the year 1859 was about 15 years. According to the Massachusetts Life Table, the number that should be surviving in 1859 was 58·6, showing the number of actual survivors to have been 4·6 less than the number demanded by such table. The deficiency (4·6 + 5·3 + 2·6 = 12·5) of actual survivors relative to the number that should survive of those admitted during the three years 1844, 1845, and 1846, was, according to the Massachusetts Table, 8·9 per cent. of (58·6 + 37·3 + 44·6 = 140·5) the number demanded; and the deficiency of actual survivors relative to the number that should survive of those admitted during the seven years 1839 to 1845 inclusive, was, according to the same life table, 8·7 per cent. of the number demanded. In like manner may be read the results derived from comparison with the English Life Table.

TABLE III.—*Summary of the results presented in the two preceding Tables, comparing the relative vitality (or ability to resist destructive influences of the Blind, at divers ages of life, and also at divers periods after admission, according to the combined experience of seven American State Institutions for the Blind, with that of the population of Massachusetts and England respectively. Calculated by Mr E. B Elliott, Consulting Actuary, Boston.*

Deficiency in the number of the Blind that survived in 1859, relative to the number that should then be surviving.

All ages.	8·9	10·3								

Note.—This table may be read thus:—Of the number of persons admitted to the above-mentioned institutions, between the ages of 10 and 14, the number that was surviving in 1859 was 8·6 per cent. *less* according to the Massachusetts Life Table, and 9·4 per cent. *less* according to the English Life Table, than the number that should then be surviving. Of the number of persons admitted during the *three* years 1838-40, from which the average time elapsing to the middle of 1859 was 20·0 years, the number that survived in 1859 was 12 3 per cent. *less* according to the Massachusetts Table, and 15·4 per cent. *less* according to the English Table, than the number that should then have been surviving. Of the number of persons admitted during the *seven* years 1839-45, from which the average time elapsing to the middle of 1859 was 16·6 years, the number that survived in 1859 was 8·7 per cent. *less* according to the Massachusetts Table, and 11·1 per cent *less* according to the English Table, than the number that should then have been surviving.

[1] Excess.

According to the first table, it appears that, of the entire 1102 persons admitted whose after-history is known, 878 now survive, whereas the Life Table of Massachusetts calls for about 979 survivors, thereby indicating that the power of the blind, represented by the returns of these institutions, to resist destructive influences is about 9 per cent. (10·3) *less* than that of the population of all England, and that the number of deaths is from 60 to 80 per cent. *greater*, according to the tables employed for the comparison, than the number required by such tables.

If we could draw our statistics from the blind as a whole, and not from the favoured few who have been taught in schools, the average duration of life would be much less. We should probably find the average amount of vital force, or power to resist destructive agencies, to be nearly one-fifth less than that of ordinary persons.

It is well known that the blind as a class are happy, contented, and cheerful. There are exceptions, of course, and it is unfortunate that Milton should have been one of them, because his eminence as a poet and scholar makes his example conspicuous, and his words to be taken as the natural language of a class of unfortunates. There have been others more admirable in this respect, for they set forth in their lives and conversation the sublime moral height to which men may attain by grasping courageously the nettle misfortune, and 'plucking thence the flower' happiness." (F. J. C.)

BLOCH, MARK ELIEZER, a German naturalist, born at Ansbach, of very poor Jewish parents, about the year 1730. Having entered the employment of a surgeon at Hamburg, he was enabled by his own exertions to supply the want of early education, and made great progress in the study of anatomy, as well as in the other departments of medical science. After taking his degree as doctor at Frankfort-on-the-Oder he established himself as a physician at Berlin, and found means to collect there a valuable museum of objects from all the three kingdoms of nature, as well as an extensive library. His first work of importance was an essay on the different species of worms found in the bodies of other animals, which gained the prize offered by the Academy of Copenhagen. Many of his papers on different subjects of natural history, comparative anatomy, and physiology, were published in the collections of the various academies of Germany, Holland, and Russia, particularly in that of the Friendly Society of Naturalists at Berlin. But his greatest work was his *Allgemeine Naturgeschichte der Fische* (12 vols., 1782–95), which occupied the labour of a considerable portion of his life, and is considered to have laid the foundations of the science of ichthyology. The publication was encouraged by a large subscription, and it passed rapidly through five editions in German and in French. Bloch made little or no alteration in the systematic arrangement of Artedi and Linnæus, although he was disposed to introduce into the classification some modifications depending on the structure of the gills, especially on the presence or absence of a fifth gill, without a bony arch. To the number of genera before established he found it necessary to add nineteen new ones; and he described 176 new species, many of them inhabitants of the remotest parts of the ocean, and by the brilliancy of their colours, or the singularity of their forms, as much objects of popular admiration as of scientific curiosity. In 1797 he paid a visit to Paris, in order to examine the large collections of such subjects of natural history as had been inaccessible to him on the shores of the Baltic; and he returned to Berlin by way of Holland. His health, which had hitherto been unimpaired, began now to decline. He went to Carlsbad for its recovery, but his constitution was exhausted, and he died there on the 6th of August 1799.

BLOCK MACHINERY. A block is a case with its contained pulley or pulleys, by means of which weighty objects are hoisted or lowered with facility. There is nothing in the appearance of a block which, to an unpractised eye, would seem to require any stretch of mental ingenuity or of manual dexterity to manufacture. It is a machine apparently so rude in its structure, and so simple in its contrivance, that the name was probably given to it from its general resemblance to a log of wood, as is obviously the case with a butcher's block, a barber's block, the block of the executioner, &c. Of the two constituent parts of a ship's block, the external *shell* and the internal *sheave*, every carpenter might make the one, and every turner the other; but still block-making is a separate branch of trade, and it is necessary that it should be, for the whole efficiency of the block depends upon the proper proportions being observed between the various parts and the accuracy with which they are adjusted.

Mr Walter Taylor of Southampton took out a patent in the year 1781, to secure the benefit of some improvement he had made in the construction of the sheaves. He also shaped the shells, cut the timber, &c., by machinery driven by water, and carried on so extensive a manufacture of blocks as to be able to contract for nearly the whole supply of blocks and blockmakers' wares required for the use of the Royal Navy. Mr Dunsterville of Plymouth had a similar set of machines wrought by horse-power. Both his blocks and Taylor's were said to be superior to those constructed by the hand, though still deficient in many respects.

It would appear that it was the enormous quantity of blocks consumed in the course of a long protracted war that first called the attention of the Admiralty or Navy Board to the possibility of some reduction being made in the expense of so important an article, and to the imprudence of depending entirely on a single contractor. On these considerations, it seems to have been the intention of Government to introduce, among other improvements in Portsmouth Dockyard about 1801, a set of machines for making blocks there. About this time, too, Mr Brunel had completed a working model of certain machines for constructing, by an improved method, the shells and sheaves of blocks. This model was submitted to the inspection of the lords commissioners of the Admiralty, and it was decided to adopt Mr Brunel's more ingenious machinery.

The advantages to be gained were those common to all cases in which machine work supersedes hand labour, and consisted in the fact that, after the proper sizes of each part had been determined by careful calculation and experience, the machine could be made to observe these sizes with unerring accuracy, and so avoid all variations due to the carelessness or ignorance of the workman; these considerations are in blocks, perhaps more than in most things, of the utmost importance. Another advantage was, that the blocks could be made by Brunel's machinery about 30 per cent. cheaper than hand-made blocks had been previously obtained by contract, and the importance of this to the Admiralty in those days, when all ships were so heavily rigged, having no steam to supplement their sail power, will be sufficiently seen when it is stated that the remuneration which Brunel was to receive for his invention was agreed to be the savings of one year, and that these savings were estimated at £16,621; in addition to this he received an allowance of a guinea a day for about six years while engaged on the work, and was paid £1000 for his working model—the total amount paid to Brunel for the invention amounting to about £20,000.

The process may be described as follows:—Pieces of wood are cut roughly to the size of the block, and the first operation is then performed by the *boring-machine*, which bores a hole for the pin, and one, two, or three holes, as the case may be, for single, double, or treble blocks, to receive the first stroke of the mortising chisel; the block is next taken to the *mortising-machine*, where the mortise or mortises for the sheaves are cut; after this, to a *circular saw*, conveniently arranged for cutting off the corners and so preparing the block for the *shaping-machine*, which consists principally of two equal and parallel circular wheels

moving on the same axis, to which one of them is firmly fixed, but on which the other is made to slide; so that these two wheels may be placed at any given distance from each other, and blocks of any size admitted between their two rims or peripheries. For this purpose, both rims are divided into ten equal parts, for the reception of ten blocks, which are firmly fixed between the two wheels. When the double wheel with its ten attached blocks is put in motion, the outer surface of the blocks, or those which are farthest from the centre, strike against the edge of a chisel or gouge fixed in a movable frame, which, being made to slide in a curved direction in the line of the axis, cuts those outward faces of the blocks to their proper curvature. A contrivance is attached to the cutting tool which allows of the curvature being altered in any required way. One side being shaped, the ten blocks are then, by a single operation, each turned one fourth part round, and another side is exposed to the cutting instrument moving in the same direction as before. A third side is then turned outwards, and after that the fourth side, when the whole ten blocks are completely shaped.

The velocity with which the wheels revolve, and the great weight with which their peripheries are loaded, would make it dangerous to the workmen or bystanders, if, by the violence of the centrifugal force, any of the blocks should happen to be thrown off from the rim of the wheels; to prevent the possibility of such an accident, an iron cage or guard is placed between the workman and the machine.

The last operation is performed by the *scoring-machine*, which cuts a groove to receive the binding or strapping of the block. The binding may be of iron or rope, and is very frequently of wire rope.

The Sheaves.—The machinery employed for making this part of the block consists of a *circular saw*, by which the log is cut into plates of the thickness required for the sheaves, according to their several diameters. These plates are next carried to a *crown saw*, which bores the central hole, and at the same time reduces them to a perfect circle of the assigned diameter. The sheave, thus shaped, is next brought to the *coaking-machine*, a piece of mechanism not inferior in ingenuity to the shaping machine for the shells. A small cutter, in traversing round the central hole of the sheave, forms a groove for the insertion of the *coak* or *bush*, the shape of which is that of three semicircles, not concentric with each other, nor with the sheave, but each having a centre equally distant from that of the sheave. The manner in which the cutter traverses from the first to the second, and from this to the third semicircle, after finishing each of them, is exceedingly ingenious. So very exact and accurate is this groove cut for the reception of the metal coak, and so uniform in their shape and size are the latter cast, the casting being made not in sand but in iron moulds, that they are invariably found to fit each other so nicely that the tap of a hammer is sufficient to fix the coak in its place. The coaks are cast with small grooves or channels in the inside of their tubes, which serve to retain the oil or grease for the pins.

The sheave, with its coak thus fitted in, is now taken to the *drilling-machine*, which is kept in constant motion. In casting the coaks a mark is left in the centre of each of the three semicircles. This mark is applied by a boy to the point of the moving drill, which speedily goes through the two coaks and the intermediate wood of the sheave. Rivets are put in these holes and clenched by hand. The next operation is performed by the *facing-machine*, which has two cutters, so arranged as to finish the side and groove the edge simultaneously; then the hole for the pin is enlarged to its exact size by the *broaching-machine*. The pins, which form a very important part of the block, are now made at Portsmouth, not of *iron* but of *steel*, carefully tempered by special appliances. They are turned by a *self-acting lathe*, and are then reduced to the exact required diameter, and polished in the *pin-polishing machine*. They are also, in this machine, subjected to a proof strain proportional to their sectional area, and thus the strength of the pin is guaranteed.

The blocks are invariably made of English elm, the grain of the wood running lengthways of the block; but in Germany recently, blocks have been made with the grain of the wood running across the block, the reason being that they are less likely to be split by the pressure on the pin of the sheave. The sheaves are made of lignum vitæ.

Three machines of each description for each operation, up to and including the facing-machine, are required. The smallest sized machines will make blocks of from 4 inches to 7 inches in length, the second size from 8 inches to 11 inches, and the largest from 12 inches to 17 inches. Two sizes of the *broaching-machine*, and one *pin-polishing machine*, are sufficient. Blocks larger than 17 inches are made by hand, 26 inches being the largest used in the Royal Navy.

As will be seen from the foregoing account, all machine-made blocks are cut out of a solid piece of wood; whereas hand-made blocks, larger than about 8 inches, are usually made in pieces, filled in at the ends and riveted together. It is questionable whether a block so made is not stronger than one cut out of the solid, as in the latter case the short-grained wood at the ends of the mortises is very liable to give way. In hand-made blocks the brass coak or tail of the sheave is not made of the peculiar shape described for machine-made blocks, but is usually of a circular shape.

The machinery for Portsmouth Dockyard, on Brunel's plans, was made by Maudslay, whose firm—now the very eminent firm of Maudslay Sons and Field—has since supplied block-making machinery to the Spanish, Turkish, and Russian Governments, and also to Chatham Dockyard; the last mentioned, however, has never been used, as the machinery at Portsmouth is capable of supplying all the dockyards, the demand for blocks being much less for the steamships and ironclads than it was formerly for the old sailing ships. The first cost of this machinery is so great that no private firm has yet ventured to set it up, and the whole of the blocks used in merchant ships are made by hand-labour, assisted by a lathe and two or three other simple mechanical contrivances. (T. M.)

BLOCKADE. It appears to have been the ancient practice of belligerents at the outset of a war to forbid by proclamation all trade on the part of neutrals with the enemy, and to treat as enemies all those who contravened the proclamation; and neutrals acquiesced tacitly in this practice until the commencement of the 17th century. In the course of that century the ancient practice came into question, as imposing on the commerce of neutrals an inconvenience not justified by any adequate necessity on the part of belligerents, and it has since fallen into desuetude. Belligerents, however, have still maintained, without any question on the part of neutrals, the practice of intercepting supplies going over sea to an enemy under certain conditions, namely, when a belligerent has invested an enemy's port, with the intention of reducing the enemy to surrender from the failure of supplies, and for that object a stoppage of all supplies to such port has become a necessary operation of the war. Any attempt, under such circumstances, on the part of a neutral merchant to introduce supplies into the invested port is a direct interference with the operations of the war, and is inconsistent with neutrality, and it accordingly subjects the offending party to be treated

as an enemy by the belligerent. The question, What constitutes such a belligerent investment of an enemy's port as to create an obligation on the part of neutrals to abstain from attempting to enter it, has been much controverted since the "armed neutrality" of 1780; but all uncertainty as to the principle upon which the decision in each case must proceed, has been put an end to by the declaration of the powers assembled in congress at Paris in 1856, that "Blockades, in order to be binding, must be effective, that is to say, must be maintained by a force sufficient really to prevent access to the enemy's coast." The question of fact will still be a subject for judicial inquiry in each case of capture, whether the conditions under which a blockade has been maintained satisfy the above declaration. If an asserted blockade is maintained in a manner which satisfies the above declaration, there is no limit to the extent of an enemy's coast which may be placed under blockade. There is also a general consent amongst nations that a neutral merchant must have knowledge of a blockade in order to be liable to be treated as an enemy for attempting to break it; but there is not any uniform practice amongst nations on this subject further than that when a blockade has become notorious, the knowledge of it will be presumed against every neutral vessel which attempts to enter the blockaded port. On the other hand, where a blockade is not notorious, it is in accordance with the practice of nations to give some notice of it to neutrals; and this notice may be communicated to them either by actual warning given to each neutral vessel which seeks to cross the line of blockade, or by a constructive warning to all neutrals resulting from an official notification of the blockade on the part of the blockading power to all powers in amity with it. It is a growing practice, if not altogether an established practice, amongst nations which accredit to one another resident envoys, for belligerents to notify diplomatically to the neutral powers the fact that they have placed an enemy's port under blockade; and it is the rule of the prize courts of Great Britain and of the United States of America to hold that, where such an official notification has been made, all the subjects of the neutral powers may be presumed to have knowledge of the blockade. Other powers, amongst which France may be mentioned, have been accustomed to direct their blockading cruisers to give warning of the blockade to each vessel that attempts to cross the line of blockade, and not to capture any vessel unless she attempts to break the blockade after such warning; but the practice of France agrees with the practice of other powers in not giving such warning after a blockade has become notorious. There is, further, a general practice amongst nations to treat the act of sailing with an intention to enter a blockaded port as an unneutral act, which will warrant the capture of a neutral merchant vessel by a belligerent cruiser on any part of the high seas, unless clear evidence is forthcoming from the captured vessel that the intention has been abandoned, or that its execution was contingent on the blockade being raised. After a port has been placed under blockade, egress is prohibited to all neutral vessels, except to such as have entered the port before the blockade was established, if they come out either in ballast or with cargoes taken on board before the commencement of the blockade. No warning is required to affect such vessel with a knowledge of the blockade, and if any such vessel should succeed in passing through the blockading squadron it becomes liable to capture as good prize by a belligerent cruiser on any part of the high seas, until it has reached its port of destination, when the offence is considered to be purged. Under the ancient practice both ship and cargo were confiscable for the breach of a blockade, and even the captain and crew were liable to be treated as enemies. A milder practice is now generally observed as regards the captain and crew, and a certain equity is administered in the British and American prize courts towards the owners of cargo, where the ship and the cargo do not belong to the same parties, and the owners of the cargo have not any knowledge of the blockade, or have been unable to countermand the shipment of the cargo since the blockade has become known to them. In such cases the cargo is released, although the ship may be rightfully condemned to the captors. (T. T.)

BLOIS, the chief town of the department of Loir-et-Cher in France, is situated in the form of an amphitheatre on the steep slope of a hill on the right bank of the Loire, 35 miles S.W. of Orleans, in 47° 35′ N. lat. and 1° 29′ E. long. It is united by a bridge of the 17th century with the suburb of Vienne on the other side of the river. The houses of the older part of the town are frequently of antiquarian interest, and the streets, which are in many cases rather stairways than streets, have often a picturesque appearance. The castle is an immense structure built at different periods, part as early as the 13th century. It was the birth-place of Louis XII., and is noted as the scene of the assassination of the duke of Guise and his brother the cardinal by command of Henry III. Among the other remarkable buildings in the town are the Hôtel de Ville, the episcopal palace, now occupied by the prefecture, the cathedral of St Louis (a modern structure), and the churches of St Vincent and St Nicholas. An ancient aqueduct, cut in the solid rock by the Romans, conveys the water of several springs to a reservoir, whence it is distributed to different parts of the town. Blois is the seat of a bishopric founded by Louis XIV., and has a communal college, a normal school, and two diocesan seminaries; an exchange, a hospital, a theatre, a botanical garden, a public library, and an agricultural society. It manufactures gloves, hosiery, hardware, and pottery, and has a considerable trade in wine, brandy, and timber. Population in 1872, 17,475. Though possibly existing under the Roman empire, Blois is first distinctly mentioned by Gregory of Tours in the 6th century, and does not become of much importance till the 9th or 10th, when it forms the chief town of a countship. From that date it appears very frequently in French history. In 1577 and 1588 the States-General were held in the city.

BLOMFIELD, Charles James, bishop of London, was born on the 29th May 1786, at Bury-St-Edmund's. He received his first education at his father's school in that town, and was then transferred to the grammar school, where, under the able instruction of the Rev. M. T. Becher, he laid the foundations of an unusually sound and thorough classical scholarship. His career at Trinity College, Cambridge, which he entered in 1804, was brilliant. He gained the Browne medals for Latin and Greek odes, and carried off the Craven scholarship. In 1808 he graduated as third wrangler and first medallist, and in the following year was elected to a fellowship at Trinity College. The first-fruits of his scholarship was an edition of the *Prometheus* of Æschylus, in 1810; this was followed by editions of the *Septem contra Thebas*, *Persæ*, *Choephoræ*, and *Agamemnon*, of Callimachus, and of the fragments of Sappho, Sophron, and Alcæus. Blomfield, however, soon ceased to devote himself to mere scholarship. He had been ordained in 1810, and held for a short time the curacy of Chesterford. He was then presented to the rectory of Quarrington, and shortly afterwards to that of Dunton, in Buckinghamshire, where he remained for about five years. In 1817 he was moved to the benefices of Great and Little Chesterford and Tuddenham, and he was in the same year appointed private chaplain to Howley, bishop of London. In 1819 he was nominated by Lord Liverpool to the rich living of St Botolph's, Bishopsgate, and in 1822

he became archdeacon of Colchester. Two years later he was raised to the bishopric of Chester, and in that position began his career of incessant labour for the advancement of the church. Many reforms were needed in the diocese, and the new bishop's energy and ardour succeeded in effecting much, though not without stirring up enemies. In 1828 he was transferred to a wider sphere of activity, being raised to the bishopric of London. This important office he held for eight-and-twenty years, labouring incessantly in a field where unremitting exertion was absolutely necessary. He gave his whole heart to the endeavour to extend the influence and efficiency of the church, and his strenuous activity was not without result. In all political or social movements which concerned the church the bishop took a prominent part. He was noted as being one of the best debaters on the episcopal bench in the House of Lords; he took a leading position in the action for church reform, which culminated in the Ecclesiastical Commission; and he did much for the extension of the colonial episcopate. His health gave way under his unceasing labours, and in 1856 he was permitted to resign his bishopric, retaining Fulham palace as his residence, along with a pension of £6000 per annum. He died at Fulham on the 5th August 1857. In private life Blomfield was warm-hearted, genial, and kindly; he was fond of travelling and of intellectual society, in which he was well qualified to shine. His published works, exclusive of those above mentioned, consist of charges, sermons, lectures, and pamphlets, and of a *Manual of Private and Family Prayers*. He was a frequent contributor to the quarterly reviews, chiefly on classical subjects. An admirable memoir has been published by the bishop's son, *Memoirs of Charles James Blomfield, D.D., Bishop of London, with Selections from his Correspondence*, edited by his son, Alfred Blomfield, M.A., &c., 1863. See also Biber, *Bishop Blomfield and his Times*, 1857.

BLONDEL, David, a Protestant clergyman, distinguished by his proficiency in ecclesiastical and civil history, was born at Chalons-sur-Marne in 1591, and died in 1665. In 1650 he succeeded G. J. Vossius in the professorship of history at Amsterdam. His works were very numerous, and were remarkable even at that period for obscurity of style. The most celebrated of them was the dissertation on Pope Joan, in which he came to the conclusion that the whole story was a mere myth. Considerable Protestant indignation was excited against him on account of this book.

BLOOD. See Anatomy and Physiology.

BLOOD, Thomas, generally known by the appellation of *Colonel Blood*, was a disbanded officer of the Parliamentary army. Bearing a grudge against the duke of Ormond, who had defeated a conspiracy he engaged in to surprise the castle of Dublin, Blood seized the duke one night in his coach in St James's Street, and carried him off a considerable distance, resolving to hang him at Tyburn; but Ormond struggled for his liberty and was rescued by his servants. Soon after, in 1671, Blood formed the design of carrying off the crown and regalia from the Tower,—an attempt which very nearly proved successful. He had bound and wounded Edwards, the keeper of the jewel-office, and had escaped out of the Tower with his prey; but he was overtaken and seized, together with some of his associates. One of these was known to have been concerned in the attempt upon Ormond, and Blood was immediately concluded to be the ringleader. When questioned, he frankly avowed the enterprise, but refused to discover his accomplices. All these extraordinary circumstances induced Charles II. to seek an interview with him, which not only led to his pardon, but to the king's granting him an estate of £500 a year in Ireland, encouraging his attendance about his person, and showing him great favour. He died August 24, 1680.

BLOOMFIELD, Robert, was born of very humble parents at the village of Honington in Suffolk, in 1766. Losing his father at the age of eleven, he was apprenticed to a farmer, and could only cultivate his literary tastes by perusing such books as he could borrow. Thomson seems to have been his favourite author, and *The Seasons* inspired him with the ambition of being a poet. He came to London, and composed *The Farmer's Boy* in a garret in Bell Alley. The manuscript fell into the hands of Capel Lofft, who encouraged him to print it, and it succeeded so well, that above 26,000 copies of it were sold. His reputation was increased by the appearance of his *Rural Tales*, *Songs and Ballads*, *News from the Farm*, *Wild Flowers*, and *The Banks of the Wye*. These are of unequal merit; but all breathe a spirit of purity and enthusiasm for the beauties of nature, that place the name of Bloomfield among the most natural and amiable of our pastoral poets. The extensive sale of *The Farmer's Boy* and *Wild Flowers* seems to have done little for the benefit of the poet, who died in poverty at Shefford in Bedfordshire in 1823. His *Remains in Poetry and Verse*, 2 vols., appeared in 1824, and another edition of his poems in 1866. A selection from his correspondence, edited by Hart, appeared in 1871.

BLOUNT, Charles, younger son of Sir Henry Blount, was born at Upper Holloway, April 27, 1654, and died 1693. He gained considerable reputation as a politician and man of letters, but his abilities were not great, and his strength lay in scoffing infidelity. His *Anima Mundi, or an Historical Narration of the Opinions of the Ancients concerning Man's Soul after this Life, according to Unenlightened Nature*, gave great offence; and his translation of Philostratus's *Life of Apollonius Tyanæus* was suppressed for the flippancy and impertinence of its attacks on revealed religion. A similar work of his, called *Great is Diana of the Ephesians*, under colour of exposing superstition, struck at revelation. In 1684 he printed a kind of introduction to polite literature, under the title of *Janua Scientiarum*. His *Just Vindication of Learning and of the Liberty of the Press* (1693) is a shameless plagiarism from the *Areopagitica*. The pamphlet which he sent anonymously to Bohun, the censor, entitled *King William and Queen Mary Conquerors*, set all London in a flame, and completely attained its object, the ruin of Bohun. Indirectly it had a good result in directing attention to the folly of the censorship. After the death of his wife, he proposed to marry her sister, and wrote a letter on that subject with great learning and address; but the archbishop of Canterbury and other divines decided against him, and the lady having therefore refused him, he is said to have shot himself, or, according to Pope's account, to have given himself a mortal wound in the arm. A collected edition of his works was published in 1695 by Gildon, with a life by the editor. See Macaulay, *History*, iv. 352, *sqq.*; Lechler, *Ges. d. Englisch. Deismus*, 114–127.

BLOW, John, an English musical composer, was born in 1648 at North Collingham in Nottinghamshire. He was educated at the chapel royal, and distinguished himself by his proficiency in music, having composed several anthems at an unusually early age. In 1673 he was made a gentleman of the chapel royal, and in 1685 was named one of the private musicians of James II. In 1687 he became master of the choir of St Paul's Church; in 1695 he was elected organist of St Margaret's, Westminster, and in 1699 composer to the chapel royal. In 1700 he published his *Amphion Anglicus*, a collection of pieces of music for one, two, three, and four voices, with a figured-bass accompaniment. Doctor Burney says that in the *Amphion*

Anglicus "the union of Scottish melody with the English is first conspicuous." Blow died in 1708, and was buried in the north aisle of Westminster Abbey. None of his compositions, most of which are anthems, attain the highest order of merit.

BLOWPIPE, a tube for directing a jet of air into a fire or into the flame of a lamp or gas jet, for the purpose of producing a high temperature by complete and rapid combustion. The blowpipe has been in common use from the earliest times for soldering metals and working glass; and since 1733, when Anton Swab first applied it to analysis of mineral substances, it has become a valuable auxiliary to the mineralogist and chemist, in the chemical examination and analysis of minerals. Its application has been variously improved at the hands of Cronstedt, Bergmann, Gahn, Berzelius, Plattner, and others, but more especially by the two last-named chemists.

The simplest and oldest form of blowpipe (still used by gasfitters, jewellers, &c.), is a conical brass tube, about 7 inches in length, curved at the small end into a right angle, and terminating in a small round orifice, which is applied to the flame, while the larger end is applied to the mouth. Where the blast has to be kept up for only a few seconds, this instrument is quite serviceable; but in longer chemical operations inconvenience arises from the condensation of moisture exhaled by the lungs in the tube. Hence many blowpipes are made with a cavity for retaining the moisture. Cronstedt placed a bulb in the centre of his blowpipe. Dr Black's convenient instrument consists of a conical tube of tin plate, with a small brass tube, supporting the nozzle, inserted near the wider end, and a mouthpiece at the narrow end. One of the most suitable forms of blowpipe is that shown in fig. 1. It is Gahn's instru-

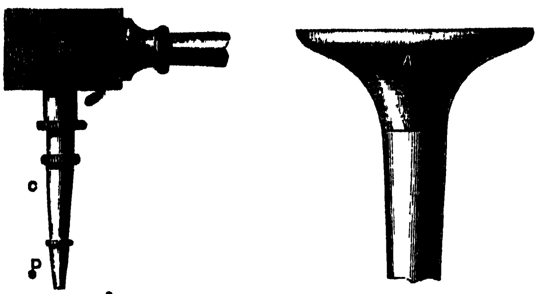

FIG. 1.—Extremities of Gahn's Blowpipe,—ordinary size.

ment as improved by Plattner. The tube A is ground to fit accurately into a socket at the top of the water-trap B, as is also the jet-pipe C. The nozzle D, of platinum, is fitted in the same manner, so that it can be easily removed and replaced while hot; *e.g.* when it is desired to remove the crust of soot which deposits upon the point when an oil-lamp or candle is used. The sizes of orifice recommended by Plattner are 0·4 and 0·5 millim. The trumpet mouthpiece, from the support it gives to the cheeks when inflated, conduces to a more steady and long-continued blast being kept up without fatigue than when the mouthpiece is inserted between the lips. Mr David Forbes has suggested the use of a double jet-pipe in connection with this instrument, so that a large or small orifice may be obtained without stopping the point; but it is doubtful whether the advantage gained is counterbalanced by the extra cost and complication. For the majority of blowpipe workers, there is probably no better instrument than Dr Black's, if provided with a properly-shaped nozzle, if possible of platinum; but where it is much used, the large-sized trumpet-mouthed instrument of Plattner is to be preferred. The instrument should be held with the first and fourth fingers passed round it, and the thumb laid along the side of the tube, the hold being steadied by resting the elbow on the table. The mode of blowing is peculiar, and requires some practice; an uninterrupted blast is kept up by the muscular action of the cheeks, while the ordinary respiration goes on through the nostrils.

If the flame of a candle or lamp be closely examined, it will be seen to consist of four parts—(*a*) a deep blue ring at the base, (*b*) a dark cone in the centre, (*c*) a luminous portion round this, and (*d*) an exterior pale blue envelope. The blue ring is formed chiefly by combustion of carbonic oxide. In the central cone the combustible vapours from the wick, though heated, are not burned, atmospheric oxygen not reaching it. In the luminous portion the supply of oxygen is not sufficient for complete combustion; the hydrogen takes up all or most of it, and carbon is precipitated in solid particles and ignited. In the exterior envelope, lastly, the temperature is highest, and combustion most complete,—sufficient oxygen being supplied to convert the carbon and hydrogen into water and carbonic acid.

In blowpipe work only two of these four parts are made use of, viz., the pale envelope, for *oxidation*, and the luminous portion, for *reduction*. To obtain a good *oxidizing flame*, the blowpipe is held with its nozzle inserted in the edge of the flame close over the level of the wick, and blown into gently and evenly. A conical jet is thus produced, consisting of an inner cone, with an outer one commencing near its apex:—the former, corresponding to (*a*) in the free flame, blue and well defined; the latter, corresponding to (*d*), pale blue and vague. The heat is greatest just beyond the point of the inner cone, combustion being there most complete. Oxidation is better effected (if a very high temperature be not required) the farther the substance is from the apex of the inner cone, so far as the heat proves sufficient, for the air has thus freer access.

To obtain a good *reducing flame* (in which the combustible matter, very hot, but not yet burned, is disposed to take oxygen from any compound containing it), the nozzle, with smaller orifice, should just touch the flame at a point higher above the wick, and a somewhat weaker current of air should be blown. The flame then appears as a long, narrow, luminous cone,—the end being enveloped by a dimly visible portion of flame corresponding to that which surrounds the free flame, while there is also a dark nucleus about the wick. The substance to be reduced is brought into the luminous portion, where the reducing power is strongest.

The flame of an oil-lamp is the best for blowpipe operations where gas is wanting; candle flame may be used when great heat is not required. The blowpipe lamp of Berzelius, supplied with colza oil, is probably the most suitable. The wick, when in use, should be carefully trimmed and clean, so as to avoid a smoking flame. The general introduction of gas has quite driven out the use of oil-lamps for blowpipe purposes in laboratories.

Various materials are used as supports for substances in the blowpipe flame; the principal are charcoal, platinum, and glass. *Charcoal* is valuable for its infusibility and low conductivity for heat (allowing substances to be strongly heated upon it), and for its powerful reducing agency by the production of carbonic oxide when ignited; so that it is chiefly employed in trying the fusibility of minerals, and in reduction. The best kind of charcoal is that of close-grained pine or alder; it is cut in short prisms, having a flat smooth surface at right angles to the rings of growth. In this a shallow hole is made with a knife or borer, for receiving the substance to be held in the flame. *Platinum* is employed in oxidizing processes, and in fusion of substances with fluxes with a view to try their solubility in them, and note the phenomena of the bead; also in observing the colouring effect of substances on the blowpipe flame (which effect is apt to be somewhat masked

by charcoal). Most commonly it is used in the form of wire, with a small bend or loop at the end. In flux experiments this loop is dipped when ignited in the powdered flux (*e.g.*, borax), then held in a lamp flame till the powder is fused; and the process is repeated, if necessary, till the loop is quite filled with a bead of the flux; to this is now added a little of the substance to be examined. Platinum is also used in the form of foil and of spoons, and for the points of forceps. Metals and easily reducible oxides, sulphides, or chlorides should not be treated upon platinum, as these substances may combine with and damage it. Tubes of hard German *glass*, 5 to 6 inches long, about ⅛th inch diameter, and open at both ends, are useful in the examination of substances containing sulphur, selenium, arsenic, antimony, and tellurium; these, when heated with access of air, evolve charactistic fumes. They are put in the tube near one end (which is held slightly depressed), and subjected to the blowpipe flame. The sublimates often condense on the cooler parts of the tube. Small tubes, closed at one end, are used, where it is required to detect the presence of water, mercury, or other bodies which are volatilized by heat without access of air.

The most important fluxes used in blowpipe analysis are carbonate of sodium, borax, and microcosmic salt. The first (which must be anhydrous and quite free from sulphates) serves chiefly in reducing metallic oxides and sulphides on charcoal, decomposing silicates, determining the presence of sulphur, and discriminating between lime and other earthy bases in minerals. Pure *borax*, or acid borate of sodium deprived of its water of crystallization by heating, is used for the purpose of dissolving up metallic oxides, when in a state of fusion at a red heat, such fused masses usually having characteristic colours when cold. In some cases the colour and transparency change on cooling. *Microcosmic salts*, or ammonio-phosphate of sodium, is used on platinum wire in the same way as borax;[1] on heating, water and ammonia are given off. The following are some other reagents for certain cases—nitrate of potash, bisulphate of potash, nitrate of cobalt, silica, fluoride of calcium, oxide or oxalate of nickel, protoxide of copper, tinfoil, fine silver, dry chloride of silver, bone ash, and litmus and Brazil-wood paper.

It may be useful here to pass briefly under review a few of the effects obtained in qualitative examinations with the blowpipe. Beginning with the *closed tube*, organic substances may be revealed by the empyreumatic odour given off, and by charring. Mercury condenses on the tube in minute globules. Selenium gives a reddish-brown, tellurium a grey, arsenic a black sublimate. Oxygen is sometimes given off, and will inflame an incandescent splinter of wood when introduced; while ammonia may be detected by red litmus paper, as also the acid or alkaline reaction of any liquid product. In the *open tube*, sulphur and sulphides give off pungent-smelling sulphurous acid gas. Selenium gives a steel-grey deposit, and an odour resembling that of horse radish. Arsenic, antimony, tellurium, yield their respective acids, forming white sublimates. The deposit from arsenic is crystalline, that from the others amorphous. In examination on *charcoal*, it is useful, in practice, to commence with pure materials and familiarize one's self with their phenomena. Most of the metals fuse in the heat of the blowpipe flame; and in the outer flame they oxidize. The noble metals do not oxidize, but they fuse. The metals platinum, iridium, rhodium, and palladium do not fuse. The incrustations (when such occur) are in each case characteristic, both in aspect and in the effects they give before the blowpipe flame. Among the most common oxides capable of reduction on charcoal alone, in the inner flame, are those of zinc, silver, lead, copper, bismuth, and antimony. The principal minerals that cannot be so reduced are those containing alkalies and alkaline earths, and the oxides of iron, manganese, and chromium. Many substances give a characteristic colour, when held by platinum forceps in the oxidizing flame. For example, arsenic, antimony, lead, colour the flame *blue*; copper, baryta, zinc, *green*; lime, lithia, strontia, *red*; potash, *violet*. Heated with *borax*, some bodies give a clear bead, both while hot and cold, except when heated by the intermittent oxidizing flame, or the flame of reduction, when the bead becomes opalescent, opaque, or milky white. The alkaline earths, tantalic and titanic acids, yttria and zirconia are examples of this. The oxides of most of the heavy metals give coloured glasses with borax, similar to those obtained by their use in glass or enamel painting. Thus oxide of cobalt gives a showy blue, and oxide of nickel a reddish-brownish colour, both being very characteristic and delicate tests of the presence of these metals. Ferric oxide gives a feeble yellow colour, which is darker while hot; but when the bead so coloured is treated in the reducing flame the iron passes into the state of ferrous oxide, giving an intensely green or nearly black colour. This reaction may be more certainly brought about by touching the bead while melted with a fragment of tin, when the ferric oxide is probably reduced at the expense of the metal. With manganese the reverse effect is produced. A bead containing a considerable quantity of manganous oxide, such as is produced by a clean reducing flame, is colourless, but when treated in the oxidizing flame the showy violet colour of the higher oxide is brought out. This reaction is a very delicate one, and is to be recommended to beginners as a test exercise in blowing a clean flame, the bead being rendered alternately coloured and colourless according as the oxidizing or reducing flame is used. Molybdic acid, which gives a black bead in the reducing, and a clear bead in the oxidizing flame, but requires more careful management, was usually recommended by Plattner to his students for this kind of exercise. Copper salts give a green bead in the oxidizing and a deep sealing-wax red in the reducing flame. This latter indication is of value in detecting a trace of copper in the presence of iron, which is done by reducing with tin as already described for iron. The effects obtained with beads of microcosmic salt, or as it is more generally called *salt of phosphorus*, are generally similar to those described for borax, but in certain cases it is to be preferred, especially in the detection of silica, which remains undissolved, and titanic acid, which can be made to assume the form of crystals similar to the natural mineral anatase by particular treatment and microscopic examination. Several new phenomena, due to the crystallization of titanic acid and similar bodies, have been described by Gustav Rose.

With *carbonate of sodium* as flux (a paste of which and the substance to be examined is made with water, and held on charcoal to the flame), three reactions may occur. The substance may fuse with effervescence, or it may be reduced, or the soda may sink into the charcoal, leaving the substance intact on the surface. The first takes place with silica, and with titanic and tungstic acids. The oxides of tungsten, antimony, arsenic, copper, mercury, bismuth, tin, lead, zinc, iron, nickel, and cobalt are reduced. Lead, zinc, antimony, bismuth, cadmium, and tellurium are volatilized partially, and form sublimates on the charcoal. Mercury and arsenic are dissipated as soon as reduced. Silica and titanic acid are the only two substances that produce a clear bead. The bead in which silica is fused is sometimes rendered yellow by the presence of sulphur. Carbonate of soda, with addition of a little nitrate of potassa, is very useful for detecting minute quantities of manganese. The fused mass, when clear, has, from the production of man-

[1] In a paper to the Royal Society, Captain Ross points out that it is better to use boric acid and phosphoric acid, instead of borax and microcosmic salts, for various analyses.

ganate of sodium, a fine green colour. (For particulars of the behaviour of different minerals before the blowpipe, see the detailed description in the article MINERALOGY.) Of late years the spectroscope has been successfully used in connection with blowpipe operations, in the detection of certain of the rarer metallic elements.

The blowpipe was first applied in the quantitative determination of metals by Harkort in 1827, and was brought to a high degree of perfection by Plattner. The methods are substantially those adopted in the assay of ores on the large scale in the wind furnace or muffle, thin capsules of clay or cavities in charcoal blocks being substituted for crucibles, and steel basins faced with bone ash, for cupels, in silver and gold assaying. From the small size of the beads obtained, especially when the ores of the precious metals are operated upon, the results are often such as cannot be weighed, and they are then measured by a tangent scale, and the weight computed from the observed diameter. This method, devised by Harkort, gives very accurate results when carefully used, but owing to the difficulty of sampling the minute quantities operated upon so as to represent the bulk of the mineral fairly, the quantitative blowpipe assay has not made much progress. Perhaps the most useful quantitative application is in the determination of nickel and cobalt. This depends upon the fact that when the compounds of these metals, as well as those of copper and iron, with arsenic, are melted in contact with an oxidizing flux, such as borax or salt of phosphorus, iron is first taken up, then cobalt, and next nickel, and finally copper; and as the oxides of these metals give very different colours to the flux, we are enabled by examining the slag to detect the exact moment at which each is removed. For the details of the process the reader is referred to Plattner's work.

Among the various arrangements which have been contrived for supplying air to the blowpipe otherwise than with the mouth, we may select that represented in the annexed figure (2) as one which is generally sufficient for

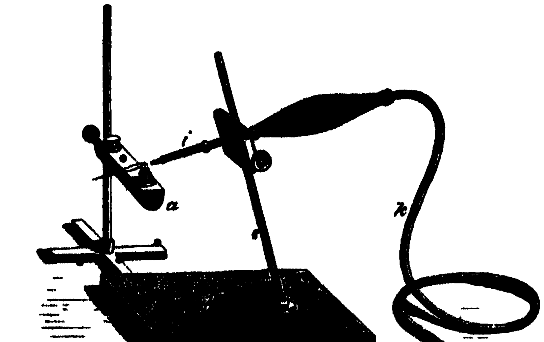

FIG. 2.—Blowpipe with Bellows.

practical purposes. It will be seen that the jet *i* is supported on a slide which can be fixed by screwing in any direction and at any height on the rod *s*, which is jointed on the board *b*. The blast can thus be adjusted variously, according to the position given to the blowpipe lamp *a*, which is of the form devised by Berzelius. The bellows B, the tube *k*, and the reservoir R, are of vulcanized india-rubber, *v* and *v'* are valves. The bellows being alternately compressed (with hand or foot) and allowed to expand, air is driven into the reservoir, and a fresh supply admitted into the bellows through *v*. After a few trials a constant blast may thus be maintained through the nozzle.

For glass-blowing ordinary coal gas is the best combustible, as the flames can be well controlled by a stopcock, and requires no trimming. The nature of the apparatus will be understood from fig. 3, which shows the burner in a horizontal section. The tube *ab* is screwed into another tube which is connected with the gas pipe *ef*. *mn* and *op* are two annular disks which support the pipe *ab*; they have a series of openings round their edges, to admit a uniform flow of gas to the narrow annular mouth between the two tubes where it joins the blast. The stopcock *f* regulates the supply of gas. The wind, supplied by double bellows fixed under the table, is sent through a lead pipe on which brass nozzles of various width can be screwed, opening into *ab*; the finer nozzles being pushed up nearly to the end of this. Elastic tubing may sometimes be used with advantage for the connections. A modified form of the apparatus is suitable for ordinary blowpipe researches of the mineralogist or chemist (see Plattner's work, 4th edition), and the apparatus used in hand-soldering of metals and other operations of the workshop is on the same principle. With suitable trunnions the blowpipe may be made to point in any direction as required.

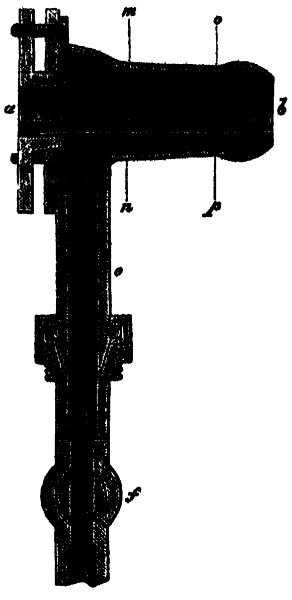

FIG. 3.—Section of Blowpipe for Glassblowing.

The soldering lamp of tinners is an example of the æolipile, an instrument which deserves some notice here. The spirit lamp *a* (fig. 4) is inserted at the bottom of a sheet-iron cylinder M N, which is open on one side, as shown. The upper part of the cylinder supports a strong cup of hammered metal, with an opening for spirits at the top (closed by a screw or cock), and a bent tube coming down from its upper part, through a slit in the cylinder to the back of the flame. The weak spirits which are put in the cup are caused to boil by the heat of the lamp, and the vapour, escaping through the bent tube, produces a jet of very hot flame. (The cup is shown separately in fig. 5.) Similar advantage is gained by causing air to pass through a quantity of some soluble hydrocarbon before it goes to the nozzle of a blowpipe.

FIG. 4.—Soldering Lamp.

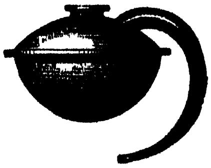

FIG. 5.—Cup of fig. 4.

There are several forms of apparatus in which water-pressure is utilized for supplying a steady blast to the blowpipe. One of these consists of a tin case, with an oblique partition reaching nearly to the bottom. The case is filled nearly three-fourths with water. Air is blown into the compartment which narrows upwards (and with which the nozzle is connected above) by a pipe reaching nearly to the bottom. This air rises through the water and accumulates above it, forcing the water up into the other compartment, which communicates freely with the outer air. The difference of water-level in the two cham-

bers thus sustains a continuous blast through the nozzle. Blowpipes have also been made on the principle of the blowing-machine known as the *trompe*. Again, the blast is sometimes supplied from a chamber in which air is condensed by means of a syringe.

The absorption of heat when an ordinary blast of cold air (with its large proportion of nitrogen) is sent into a flame is considerable; and this has suggested the employment of a hot blast for blowpipe work. Mr T. Fletcher has constructed an apparatus on this principle, which yields a very intense flame, sufficient to fuse platinum wire. The arrangement is represented in fig. 6. It will be observed that the pipe conveying the blast is coiled several times round the gas pipe (for ordinary coal-gas), and that both coil and core are heated by a row of burners placed below. The blast is furnished either with the mouth or with india-rubber bellows.

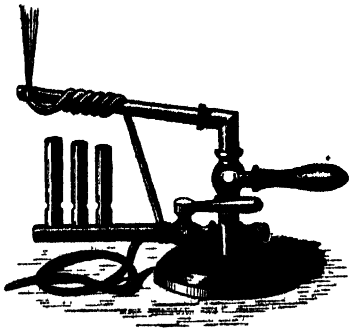

Fig. 6.—Hot-Blast Blowpipe.

The power of the blowpipe flame may be greatly increased by supplying oxygen in the place of atmospheric air; and a still greater heat is obtained by the combination of pure oxygen and hydrogen. In the latter arrangement, which constitutes the oxyhydrogen blowpipe, it is important that the oxygen and hydrogen be kept in separate reservoirs, and be only allowed to mix at the jet, otherwise explosion may occur through the flame running back through the jet to the reservoir of mixed gases. There are various methods of effecting this, which we do not stop to describe. The blue flame produced gives the most intense heat that is obtainable by artificial means, except by the electric current. Thick platinum wires are melted before it like wax in a candle flame; and earths, such as lime, magnesia, or zirconia, are raised to intense incandescence. For the application of the oxyhydrogen blowpipe to the fusion of the more refractory metals, see Platinum.

The literature of the blowpipe is very extensive. The earlier notices of the subject will be found in Berzelius's original work, of which there are English translations by Children, published in 1822, and by J. D. Whitney (of a later edition), published in Boston in 1845. The most complete work, however, is Plattner's *Probirkunst mit dem Lothrohre*, of which there are several editions; the fourth or latest, published since the author's death, has been edited by his pupil and successor, Professor Richter of Freiberg. An English translation, by Professor H. B. Cornwall, has been published in New York. For the use of the blowpipe in determining minerals, the best works are Scheerer's *Lothrohrbuch*, translated by Professor H. B. Blanford, and a *Manual of Determinative Mineralogy, with an Introduction to Blowpipe Analysis*, by Professor G. J. Brush of Yale College. In addition to these works, notices, more or less extensive, will be found in most mineralogical handbooks and works on chemical analysis. (A. B. M.)

BLÜCHER, Gebhard Leberecht von, field-marshal of the Prussian armies, prince of Wahlstadt in Silesia, was born at Rostock in 1742. In his fourteenth year he entered into the service of Sweden; and in the war between that power and Prussia he was taken prisoner. He afterwards entered into the service of Prussia, in which he became distinguished by his activity; but conceiving himself neglected by the great Frederick, he became a farmer in Silesia, and by his enterprise and perseverance in fifteen years he acquired an honourable independence. On the accession of Frederick-William II. he was recalled to military service, and replaced as major in his old regiment, the Black Hussars, where he distinguished himself in six general actions against the French, rose to the rank of colonel and major-general in 1793–4, and gained a high reputation by his energy, promptitude, and foresight. He was in a subordinate command in the disastrous battle of Jena in 1802; but he made a masterly retreat with his column to Lübeck, and extorted the praises of his adversaries, who testified on his capitulation that it was caused by "want of provisions and ammunition." He was soon exchanged for General Victor, and was actively employed in Pomerania, at Berlin, and at Königsberg, until the conclusion of the war. When Prussia shook off the French yoke in 1813, he first obtained a separate command. At the head of 60,000 troops, chiefly composed of raw militia, he defeated four French marshals at Katsbach, and rapidly crossing the Elbe, materially contributed to the signal victory of Leipsic. In several severe actions he fought his way to Paris, which he entered on 31st March 1814; and there, it has been stated, but for the intervention of the other allied commanders, he was disposed to make a severe retaliation for the calamities that Prussia had suffered from the armies of France. Blowing up the bridge of Jena across the Seine was said to be one of his contemplated acts. When war again broke out in 1815, the veteran was at the head of the Prussian armies in Belgium, and exhibited his wonted enterprise and activity. But partly owing to his own confidence and temerity, partly to the skilful strategy of his celebrated opponent, he was defeated in the severe battle of Ligny on 16th of June; yet, with his characteristic spirit and energy, Blücher rallied his defeated forces, and appeared on the field of Waterloo on the 18th, just as Wellington had repulsed the last attack of Napoleon on the British position. At that critical moment Blücher was seen emerging from the wood of Frichemont on the French right; and the simultaneous irresistible charge of the British forces converted the retreat of the French into a tumultuous flight. The allied commanders met on the Genappes road, near the farm called Maison du Roi, where the British forces were halted. The pursuit was continued through the night by sixteen fresh Prussian regiments with terrible carnage. The allies soon again entered Paris, where Blücher remained for several months; but the health of the aged commander having declined, he retired to his Silesian residence at Kirblowitz, where he died on the 12th September 1819, aged seventy-seven. The life of Blücher has been written by Varnhagen von Ense (1827), Rauschnick (1836), Bieske (1862), and Scherr (1862).

BLUMENBACH, Johann Friedrich, a distinguished physiologist, was born at Gotha on the 11th of May 1752. He studied medicine at Jena, and afterwards at Göttingen, where he took the degree of doctor in 1775. His thesis on that occasion *De Generis Humani Varietate Nativa*, published in quarto, was the germ of those craniological researches to which so many of his subsequent inquiries were directed; and such was the opinion entertained of his acquirements, that he was appointed an adjunct or extraordinary professor of medicine in the following year, and ordinary professor in 1778; soon after which period he began to enrich the pages of the *Medicinische Bibliothek*, of which he was editor from 1780 to 1794, with various contributions on medicine, physiology, and anatomy. In physiology he was of the school of Haller, and was in the habit of illustrating his theory by a careful comparison of the animal functions of man with those of the lower animals. His reputation was much extended by

the publication of his excellent *Institutiones Physiologicæ*, a condensed, well-arranged view of the animal functions, expounded without discussion of minute anatomical details. This work appeared in 1787, and between its first publication and 1821 went through many editions in Germany, where it was the general text-book of the science. It was translated into English in America by Caldwell in 1798, and in London by Elliotson in 1807.

Blumenbach was perhaps still more extensively known by his admirable *Handbuch* of comparative anatomy, of which the German editions were numerous, from its appearance in 1805 to 1824. It was translated into English in 1809 by the eminent surgeon Lawrence, and again, with the latest improvements and editions, by Coulson in 1827. This manual of Blumenbach's, though slighter than the subsequent works of Cuvier, Carus, and others, and not to be compared with such recent expositions as that of Gegenbaur, will always be esteemed for the accuracy of the author's own observations, and his just appreciation of the labours of his predecessors.

One of the most extensive of Blumenbach's works was the *Decas Collectionis suæ Craniorum Diversarum Gentium illustrata*, in which accurate though slight delineations of the skulls in his noble collection are given, with brief descriptions of each. It appeared in *fasciculi*, until sixty crania were represented,—exhibiting in a striking manner the peculiarities in form of the skulls of different nations, and justifying the division of the human race into several great varieties or families, of which he enumerated five—the Caucasian or white race, the Mongolian or Tatar, the Malayan or brown race, the Negro or black race, and the American or red race. The classification he thus proposed has been very generally received, and most later schemes have been modifications of it. For these see the article ANTHROPOLOGY, vol. ii. p. 113.

Although the greatest part of Blumenbach's long life was passed at Göttingen, in 1789 he found leisure to visit Switzerland, and gave a curious medical topography of that country in his *Bibliothek*. He was in England in 1788 and 1792. The Prince Regent conferred on him the office of physician to the royal family in Hanover in 1816, and made him knight companion of the Guelphic order in 1821. The Royal Academy of Paris elected him a member in 1831. He died at Göttingen on the 22d of January 1840.

BOA, a name formerly applied to all large Serpents, which, devoid of poison fangs, killed their prey by constriction; but now confined to that section of them occurring in America, the Old World forms being known as Pythons. The true boas are widely distributed throughout tropical America, occurring most abundantly in Guiana and Brazil, where they are found in dry sandy localities, amid forests, on the banks of rivers and lakes, and in the water itself, according to the habits of the various species. They feed chiefly on the smaller quadrupeds, in search of which they often ascend trees, suspending themselves from the branches by the tail, and thus awaiting motionless the approach of their victim. While so hanging they are partly supported by two spine-like hooks, situated one on each side of the vent, which are connected with several small bones concealed beneath the skin and attached to the main skeleton. These bones, terminating thus in an external claw, are characteristic of the family *Boidæ*, and are recognized by anatomists as the rudiments of those which form the hind limbs in all quadrupeds. The size of the boa's prey often seems enormously beyond its apparent capacity for swallowing, a difficulty which disappears on acquaintance with the peculiar structure of the creature's jaws. The bones composing these are not knit together as in Mammals, but are merely connected by ligaments, which can be distended at pleasure. The mouth of the boa can thus be made to open transversely as well as vertically; and in addition to this the two jaws are not connected directly as in other animals, but by the intervention of a distinct bone, which adds greatly to the extent of its gape. It has also the power of moving one half of the jaw independently of the other, and can thus keep a firm hold of its victim while gradually swallowing it. The boa possesses a double row of solid sharp teeth in the upper jaw, and a single row beneath, all pointing inwards, so that, its prey once caught, it would be well-nigh impossible even for the boa itself to release it. After feeding, boas, like all other reptiles, become inactive, and remain so while the process of digestion is going on, which, in the case of a full meal, may extend over a few weeks, and during this period they are readily killed. All the species are ovoviviparous. The Jiboya or *Boa constrictor*—the latter name having been loosely given to all the species—is an inhabitant of the dry and sandy districts of tropical America, and rarely exceeds 20 feet in length. Its food consists chiefly of the agoutis, capybaras, and ant-bears, which abound in those districts. It seeks to avoid man, and is not feared by the inhabitants, who kill it readily with a sharp blow from a stick. The Water-Boa or Anaconda (*Eunectens murinus*) is a much more formidable creature, attaining, it is said, a length of 40 feet, and being thus probably the largest of living serpents. It inhabits the lakes, rivers, and marshes of Brazil and Guiana, and passes a considerable portion of its existence in the water. It is exceedingly voracious, feeding on fishes and on such animals as may come to the banks of the stream to drink, for which it lies in wait with only a small part of its head above the surface of the water. It also occasionally visits the farmyards, carrying off poultry and young cattle, and it has been known to attack man.

BOADICEA, a British queen in the time of the Emperor Nero. She was wife of Prasutagus, king of the Iceni, a people inhabiting the eastern coast of Britain. On his deathbed, 60 A.D., Prasutagus named the emperor heir to his accumulated treasures conjointly with his own two daughters, in expectation of securing thereby Nero's protection for his family and people; but he was no sooner dead than the emperor's officers seized all. Boadicea's opposition to these unjust proceedings was resented with such cruelty, that orders were given that she should be publicly whipped, and her daughters exposed to the brutality of the soldiers. The Britons took up arms, with Boadicea at their head, to shake off the Roman yoke; the colony of Camalodunum or Colchester was taken, and the Romans were massacred wherever they could be found. The whole province of Britain would have been lost to Rome, if Suetonius Paulinus had not hastened from the Isle of Mona, and at the head of 10,000 men engaged the Britons, who are said to have amounted to 230,000. A great battle was fought, which resulted in the complete defeat of the Britons (62 A.D.) Boadicea, who had displayed extraordinary valour, soon after despatched herself by poison. (Tac. *Ann.* xiv. *Agric.*, 15–16; Dion Cass. lxii.)

BOAR, WILD (*Sus scrofa*), an important species of *Suidæ*, a family of Pachydermatous Mammals, and generally regarded as the original stock of our domestic breeds of swine. In size it is equal to the largest of the domestic kinds, while exceeding them all in strength of body and in ferocity of disposition. It is of a greyish-black colour, covered with short woolly hair, thickly interspersed with coarse stiff bristles, which assume the form of a mane along the spine. The canine teeth are largely developed, forming two pairs of prism-shaped tusks, which thus become formidable weapons. In old age those tusks in the lower jaw gradually curve inwards and upwards over

the snout until they are rendered useless for purposes of attack, when, according to Darwin, they become serviceable for defence in the frequent fights which take place during the rutting season. At the same time, the canines of the upper jaw begin to develop outwards and upwards, and these take the place of the lower ones as offensive weapons. The wild boar is a native of the temperate regions of Europe and Asia, where it inhabits the deepest recesses of forests and marshy grounds. Vambery, in his recent journey through Central Asia, found them in enormous numbers in the extensive swamps of Turkestan. They appear to have been denizens of British forests at least till the reign of Henry II., after which they are not heard of till the time of Charles I., when an attempt to restock the New Forest with them failed. In the reign of William the Conqueror any one killing a wild boar was liable to have his eyes put out. After reaching maturity the boar becomes a solitary animal, unless during the breeding season, when it seeks the female, and at this time they engage in fierce contests with each other, although these, it is said, seldom lead to fatal results, as they contrive to receive the blows on their tusks, or on the specially tough skin which covers their shoulders. The Indian Wild Boar (*Sus indicus*) is undoubtedly polygamous, and there are several facts which point to a similar habit in the European boar. Both species are nocturnal, issuing from their coverts at twilight in quest of food. This is chiefly of a vegetable nature, consisting of roots which it ploughs up by means of its broad muscular snout and of grain; although they are also known to devour the smaller mammals, birds, and eggs. The female is ordinarily a timid creature, but shows great courage and fierceness in defence of its young. It associates with other females for mutual protection against wolves. The wild boar was for many centuries a favourite beast of chase with the nobility of Europe. It was hunted on foot with the spear,—its great strength, and its ferocity when at bay, rendering the sport alike exciting and dangerous. The gun has now superseded the spear in European boar-hunting, but owing to the comparative scarcity of the boars it is now little practised. In India, however, where these animals abound in the jungles, it is still a favourite sport, the boar being pursued on horseback and speared. The bristles of the boar are much used in the manufacture of brushes.

BOAT-BUILDING. See SHIP-BUILDING.

BOBRUISK, a town of Russia, in the government of Minsk, 110 miles S.E. of that city, in 53° 15′ N. lat. and 28° 52′ E. long., on the right bank of the Berezina, near the confluence of the Bobruiska, on the high road from Mogileff to Brest-Litovsk. Bobruisk was an unimportant place in 1508, when the Moscovite army, sent by the Emperor Basil against the Polish king Sigismund, advanced towards it. In the 17th century there existed a castle, which was burned down in 1649. When the Minsk government was incorporated with Russia, Bobruisk was a small borough; but in 1795 it was raised to the rank of chief town of a department in the Minsk government. In the beginning of the reign of Alexander I. there was erected at Bobruisk, by the advice of General Osterman, a fort, which obtained great importance in 1812, and was made equal to the best in Europe by the Emperor Paul I. The fort proper is built on a height exactly at the confluence of the Bobruiska with the Berezina, nearly a mile from the town. On the right bank of the former river is another small fort, called Fort Frederick William, well supported by a line of defences. In 1860 the population of Bobruisk was 23,761, of whom 11,394 were Jews. It has 2 Greek churches, 17 synagogues, a military hospital, and a departmental college. The only industrial establishments are two potteries. On the river near the town there is a harbour, by which grain and salt are imported from the southern governments.

BOCCACCIO, GIOVANNI. Comparatively little is known of Boccaccio's life, particularly of the earlier portion of it. He was born in 1313, as we know from a letter of Petrarch, in which that poet, who was born in 1304, calls himself the senior of his friend by nine years. The place of his birth is somewhat doubtful,—Florence, Paris, and Certaldo being all mentioned by various writers as his native city. Boccaccio undoubtedly calls himself a Florentine, but this may refer merely to the Florentine citizenship acquired by his grandfather. The claim of Paris has been supported by Baldelli and Tiraboschi, mainly on the ground that his mother was a lady of good family in that city, where she met Boccaccio's father. The balance of evidence is decidedly in favour of Certaldo, a small town or castle in the valley of the Elsa, 20 miles from Florence, where the family had some property, and where the poet spent much of the latter part of his life. He always signed his name Boccaccio da Certaldo, and named that town as his birthplace in his own epitaph. Petrarch calls his friend Certaldese; and Filippo Villani, a contemporary, distinctly says that Boccaccio was born in Certaldo.

Boccaccio, an illegitimate son, as is put beyond dispute by the fact that a special licence had to be obtained when he desired to become a priest, was brought up with tender care by his father, who seems to have been a merchant of respectable rank. His elementary education he received from Giovanni da Strada, an esteemed teacher of grammar in Florence. But at an early age he was apprenticed to an eminent merchant, with whom he remained for six years, a time entirely lost to him, if we may believe his own statement. For from his tenderest years his soul was attached to that "*alma poesis*," which, on his tombstone he names as the task and study of his life. In one of his works he relates that, in his seventh year, before he had ever seen a book of poetry or learned the rules of metrical composition, he began to write verse in his childish fashion, and earned for himself amongst his friends the name of "the poet." It is uncertain where Boccaccio passed these six years of bondage; most likely he followed his master to various centres of commerce in Italy and France. We know at least that he was in Naples and Paris for some time, and the youthful impressions received in the latter city, as well as the knowledge of the French language acquired there, were of considerable influence on his later career. Yielding at last to his son's immutable aversion to commerce, the elder Boccaccio permitted him to adopt a course of study somewhat more congenial to the literary tastes of the young man. He was sent to a celebrated professor of canon law, at that time an important field of action both to the student and the practical jurist. According to some accounts—far from authentic, it is true—this professor was Cino da Pistoia, the friend of Dante, and himself a celebrated poet and scholar. But, whoever he may have been, Boccaccio's master was unable to inspire his pupil with scientific ardour. "Again," Boccaccio says, "I lost nearly six years. And so nauseous was this study to my mind, that neither the teaching of my master, nor the authority and command of my father, nor yet the exertions and reproof of my friends, could make me take to it, for my love of poetry was invincible."

About 1333 Boccaccio settled for some years at Naples, apparently sent there by his father to resume his mercantile pursuits, the canon law being finally abandoned. The place, it must be confessed, was little adapted to lead to a practical view of life one in whose heart the love of poetry was firmly rooted. The court of King Robert of Anjou at Naples was frequented by many Italian and French men of letters, the great Petrarch amongst the

number. At the latter's public examination in the noble science of poetry by the king, previous to his receiving the laurel crown at Rome, Boccaccio was present,—without, however, making his personal acquaintance at this period. In the atmosphere of this gay court, enlivened and adorned by the wit of men and the beauty of women, Boccaccio lived for several years. We can imagine how the tedious duties of the market and the counting-house became more and more distasteful to his aspiring nature. We are told that finding himself by chance on the supposed grave of Virgil, near Naples, Boccaccio on that sacred spot took the firm resolution of devoting himself for ever to poetry. But perhaps another event, which happened some time after, led quite as much as the first mentioned occurrence to this decisive turning point in his life. On Easter-eve, 1341, in the church of San Lorenzo, Boccaccio saw for the first time the natural daughter of King Robert, Maria, whom he immortalized as Fiammetta in the noblest creations of his muse. Boccaccio's passion on seeing her was instantaneous, and (if we may accept as genuine the confessions contained in one of her lover's works) was returned with equal ardour on the part of the lady. But not till after much delay did she yield to the amorous demands of the poet, in spite of her honour and her duty as the wife of another. All the information we have with regard to Maria or Fiammetta is derived from the works of Boccaccio himself, and owing to several apparently contradictory statements occurring in these works, the very existence of the lady has been doubted by commentators, who seem to forget that, surrounded by the chattering tongues of a court, and watched perhaps by a jealous husband, Boccaccio had all possible reason to give the appearance of fictitious incongruity to the effusions of his real passion. But there seems no more reason to call into question the main features of the story, or even the identity of the person, than there would be in the case of Petrarch's Laura or of Dante's Beatrice. It has been ingeniously pointed out by Baldelli, that the fact of her descent from King Robert being known only to Maria herself, and through her to Boccaccio, the latter was the more at liberty to refer to this circumstance,—the bold expression of the truth serving in this case to increase the mystery with which the poets of the Middle Ages loved, or were obliged, to surround the objects of their praise. From Boccaccio's *Ameto* we learn that Maria's mother was, like his own, a French lady, whose husband, according to Baldelli's ingenious conjecture, was of the noble house of Aquino, and therefore of the same family with the celebrated Thomas Aquinas. Maria died, according to his account, long before her lover, who cherished her memory to the end of his life, as we see from a sonnet written shortly before his death.

The first work of Boccaccio, composed by him at Fiammetta's command, was the prose tale, *Filocopo*, describing the romantic love and adventures of Florio and Biancafiore, a favourite subject with the knightly minstrels of France, Italy, and Germany. The treatment of the story by Boccaccio is not remarkable for originality or beauty, and the narrative is encumbered by classical allusions and allegorical conceits. The style also cannot be held worthy of the future great master of Italian prose. Considering, however, that this prose was in its infancy, and that this was Boccaccio's first attempt at remoulding the unwieldy material at his disposal, it would be unjust to deny that *Filocopo* is a highly interesting work, full of promise and all but articulate power.

Another work, written about the same time by Fiammetta's desire and dedicated to her, is the *Teseide*, an epic poem, and indeed the first heroic epic in the Italian language. The name is chosen somewhat inappropriately, as King Theseus plays a secondary part, and the interest of the story centres in the two noble knights, Palemone and Arcito, and their wooing of the beautiful Emelia. The *Teseide* is of particular interest to the student of poetry, because it exhibits the first example of the *ottava rima*, a metre which has been adopted by Tasso and Ariosto, and in our own language by Byron in his *Don Juan*. Another link between Boccaccio's epic and our literature is formed by the fact of Chaucer having in the *Knight's Tale* adopted its main features.

Boccaccio's poetry has been severely criticized by his countrymen, and most severely by the author himself. On reading Petrarch's sonnets, Boccaccio resolved in a fit of despair to burn his own attempts, and only the kindly encouragement of his great friend prevented the holocaust. Posterity has justly differed from the author's sweeping self-criticism. It is true, that compared with Dante's grandeur and passion, and with Petrarch's absolute mastership of metre and language, Boccaccio's poetry seems to be somewhat thrown into shade. His verse is occasionally slip-shod, and particularly his epic poetry lacks what in modern parlance is called poetic diction,—the quality, that is, which distinguishes the elevated pathos of the recorder of heroic deeds from the easy grace of the mere *conteur*. This latter feature, so charmingly displayed in Boccaccio's prose, has to some extent proved fatal to his verse. At the same time, his narrative is always fluent and interesting, and his lyrical pieces, particularly the poetic interludes in the *Decameron*, abound with charming gallantry, and frequently rise to lyrical pathos.

About the year 1341 Boccaccio returned to Florence by command of his father, who in his old age desired the assistance and company of his son. Florence, at that time disturbed by civil feuds, and the silent gloom of his father's house could not but appear in an unfavourable light to one accustomed to the gay life of the Neapolitan court. But more than all this, Boccaccio regretted the separation from his beloved Fiammetta. The thought of her at once embittered and consoled his loneliness. Three of his works owe their existence to this period. With all of them Fiammetta is connected; of one of them she alone is the subject.

The first work, called *Ameto*, describes the civilizing influence of love, which subdues the ferocious manners of the savage with its gentle power. Fiammetta, although not the heroine of the story, is amongst the nymphs who with their tales of true love soften the mind of the huntsman.

Ameto is written in prose alternating with verse, specimens of which form occur in old and middle-Latin writings. It is more probable, however, that Boccaccio adopted it from that sweetest and purest blossom of mediæval French literature, *Aucassin et Nicolette*, which dates from the 13th century, and was undoubtedly known to him. So pleased was Boccaccio with the idea embodied in the character of *Ameto* that he repeated its essential features in the Cimone of his *Decameron* (Day 5th, tale i.)

The second work referred to is a poem in fifty chapters, called *L'amorosa Visione*. It describes a dream in which the poet, guided by a lady, sees the heroes and lovers of ancient and mediæval times. Boccaccio evidently has tried to imitate the celebrated *Trionfi* of Petrarch, but without much success. There is little organic development in the poem, which reads like the *catalogue raisonné* of a picture gallery; but it is remarkable from another point of view. It is perhaps the most astounding instance in literature of ingenuity wasted on trifles; even Edgar Poe, had he known Boccaccio's puzzle, must have confessed himself surpassed. For the whole of the *Amorosa Visione* is nothing but an acrostic on a gigantic scale. The poem

is written, like the *Divina Commedia*, in *terza rima*, and the initial letters of all the triplets throughout the work compose three poems of considerable length, in the first of which the whole is dedicated to Boccaccio's lady-love, this time under her real name of Maria. In addition to this, the initial letters of the first, third, fifth, seventh, and ninth lines of the dedicatory poem form the name of Maria; so that here we have the acrostic in the second degree. No wonder that thus entrammelled the poet's thought begins to flag and his language to halt.

The third important work written by Boccaccio during his stay at Florence, or soon after his return to Naples, is called *L'amorosa Fiammetta;* and although written in prose, it contains more real poetry than the elaborate production just referred to. It proports to be Fiammetta's complaint after her lover, following the call of filial duty, had deserted her. Bitterly she deplores her fate, and upbraids her lover with coldness and want of devotion. Jealous fears add to her torture, not altogether unfounded, if we believe the commentators' assertion that the heroine of *Ameto* is in reality the beautiful Lucia, a Florentine lady loved by Boccaccio. Sadly Fiammetta recalls the moments of former bliss, the first meeting, the stolen embrace. Her narrative is indeed our chief source of information for the incidents of this strange love-story. It has been thought unlikely, and indeed impossible, that Boccaccio should thus have become the mouthpiece of a real lady's real passion for himself; but there seems nothing incongruous in the supposition that after a happy reunion the poet should have heard with satisfaction, and surrounded with the halo of ideal art, the story of his lady's sufferings. Moreover, the language is too full of individual intensity to make the conjecture of an entirely fictitious love affair intrinsically probable. *L'amorosa Fiammetta* is a monody of passion sustained even to the verge of dulness, but strikingly real, and therefore artistically valuable.

By the intercession of an influential friend, Boccaccio at last obtained (in 1344) his father's permission to return to Naples, where in the meantime Giovanna, grand-daughter of King Robert, had succeeded to the crown. Being young and beautiful, fond of poetry and of the praise of poets, she received Boccaccio with all the distinction due to his literary fame. For many years she remained his faithful friend, and the poet returned her favour with grateful devotion. Even when the charge of having instigated, or at least connived at, the murder of her husband was but too clearly proved against her, Boccaccio was amongst the few who stood by her, and undertook the hopeless task of clearing her name from the dreadful stain. It was by her desire, no less than by that of Fiammetta, that he composed (between 1344 and 1350) most of the stories of his *Decameron*, which afterwards were collected and placed in the mouths of the Florentine ladies and gentlemen. During this time he also composed the *Filostrato*, a narrative poem, the chief interest of which, for the English reader, lies in its connection with Chaucer. With a boldness pardonable only in men of genius, the great English poet has adopted the main features of the plot, and has literally translated parts of Boccaccio's work, without so much as mentioning the name of his Italian source.[1]

In 1350 Boccaccio returned to Florence, owing to the death of his father, who had made him guardian to his younger brother Jacopo. He was received with great distinction, and entered the service of the Republic, being at various times sent on important missions to the margrave of Brandenburg, and to the courts of several popes, both in Avignon and Rome. Boccaccio boasts of the friendly terms on which he had been with the great potentates of Europe, the emperor and pope amongst the number. But he was never a politician in the sense that Dante and Petrarch were. As a man of the world he enjoyed the society of the great, but his interest in the internal commotions of the Florentine state seems to have been very slight. Besides, he never liked Florence, and the expressions used by him regarding his fellow-citizens betray anything but patriotic prejudice. In a Latin eclogue he applies to them the term "Batrachos" (frog), by which, he adds parenthetically—*Ego intelligo Florentinorum morem; loquacissimi enim sumus, verum in rebus bellicis nihil valemus.* The only important result of Boccaccio's diplomatic career was his intimacy with Petrarch. The first acquaintance of these two great men dates from the year 1350, when Boccaccio, then just returned to Florence, did all in his power to make the great poet's short stay in that city agreeable. When in the following year the Florentines were anxious to draw men of great reputation to their newly-founded university, it was again Boccaccio who insisted on the claims of Petrarch to the most distinguished position. He himself accepted the mission of inviting his friend to Florence, and of announcing to Petrarch at the same time that the forfeited estates of his family had been restored to him. In this manner an intimate friendship grew up between them to be parted only by death. Common interests and common literary pursuits were the natural basis of their friendship, and both occupy prominent positions in the early history of that great intellectual revival commonly called *Renaissance*.

During the 14th century the study of ancient literature was at a low ebb in Italy. The interest of the lay world was engrossed by political struggles, and the treasures of classical history and poetry were at the mercy of monks, too lazy or too ignorant to use, or even to preserve them. Boccaccio himself told that, on asking to see the library of the celebrated monastery of Monte Casino, he was shown into a dusty room without a door to it. Many of the valuable manuscripts were mutilated; and his guide told him that the monks were in the habit of tearing leaves from the codices to turn them into psalters for children, or amulets for women at the price of four or five *soldi* a piece. Boccaccio did all in his power to remove by word and example this barbarous indifference. He bought or copied with his own hand numerous valuable manuscripts, and an old writer remarks that if Boccaccio had been a professional copyist, the amount of his work might astonish us. His zealous endeavours for the revival of the all but forgotten Greek language in western Europe are well known. The most celebrated Italian scholars about the beginning of the 15th century were unable to read the Greek characters. Boccaccio deplored the ignorance of his age. He took lessons from Leone Pilato, a learned adventurer of the period, who had lived a long time in Thessaly and, although born in Calabria, pretended to be a Greek. By Boccaccio's advice Leone Pilato was appointed professor of Greek language and literature in the university of Florence, a position which he held for several years, not without great and lasting benefit for the revival of classical learning. Boccaccio was justly proud of having been intimately connected with the foundation of the first chair of Greek in Italy. But he did not forget, in his admiration of classic literature, the great poets of his own country. He never tires in his praise of the sublime Dante, whose works he copied with his own hand. He conjures his friend Petrarch to study the great Florentine, and to defend himself against

[1] Among the publications of the Chaucer Society for 1873 the reader will find a careful analysis of *Filostrato*, together with an English translation of the lines partly or entirely embodied in Chaucer's poem, by Mr W. M. Rossetti. The parallel between the treatment of the same story by two poets, both great in their individual spheres, and both in a manner representative of their national types of literature, is of engrossing interest.

the charges of wilful ignorance and envy brought against him. A life of Dante, and the commentaries on the first 16 cantos of the *Inferno*, bear witness to Boccaccio's learning and enthusiasm.

In the chronological enumeration of our author's writings we now come to his most important work, the *Decameron*, a collection of one hundred stories, published in their combined form in 1353, although mostly written at an earlier date. This work marks in a certain sense the rise of Italian prose. It is true that Dante's *Vita Nuova* was written before, but its involved sentences, founded essentially on Latin constructions, cannot be compared with the infinite suppleness and precision of Boccaccio's prose. The *Cento Novelle Antiche*, on the other hand, which also precedes the *Decameron* in date, can hardly be said to be written in artistic language according to definite rules of grammar and style. Boccaccio for the first time speaks a new idiom, flexible and tender, like the character of the nation, and capable of rendering all the shades of feeling, from the coarse laugh of cynicism to the sigh of hopeless love. It is by the name of "Father of Italian Prose" that Boccaccio ought to be chiefly remembered.

Like most progressive movements in art and literature, Boccaccio's remoulding of Italian prose may be described as a "return to nature." It is indeed the nature of the Italian people itself which has become articulate in the *Decameron;* here we find southern grace and elegance, together with that unveiled *naïveté* of impulse which is so striking and so amiable a quality of the Italian character. The undesirable complement of the last-mentioned feature, a coarseness and indecency of conception and expression hardly comprehensible to the northern mind, also appears in the *Decameron*, particularly where the life and conversation of the lower classes are the subject of the story. At the same time, these descriptions of low life are so admirable, and the character of popular parlance rendered with such humour, as often to make the frown of moral disgust give way to a smile.

It is not surprising that a style so concise and yet so pliable, so typical and yet so individual, as that of Boccaccio was of enormous influence on the further progress of a prose in a manner created by it. This influence has indeed prevailed down to the present time, to an extent beneficial upon the whole, although frequently fatal to the development of individual writers. Novelists like Giovanni Fiorentino or Franco Sacchetti are completely under the sway of their great model; and Boccaccio's influence may be discerned equally in the plastic fulness of Machiavelli and in the pointed satire of Aretino. Without touching upon the individual merits of Lasca, Bandello, and other novelists of the *cinquecento*, it may be asserted that none of them created a style independent of their great predecessor. One cannot indeed but acquiesce in the authoritative utterance of the Accademia della Crusca, which holds up the *Decameron* as the standard and model of Italian prose. Even the Della Cruscan writers themselves have been unable to deprive the language wholly of the fresh spontaneity of Boccaccio's manner, which in modern literature we again admire in Manzoni's *Promessi sposi.*

A detailed analysis of a work so well known as the *Decameron* would be unnecessary. The description of the plague of Florence preceding the stories is universally acknowledged to be a masterpiece of epic grandeur and vividness. It ranks with the paintings of similar calamities by Thucydides, Defoe, and Manzoni. Like Defoe, Boccaccio had to draw largely on hearsay and his own imagination, it being almost certain that in 1348 he was at Naples, and therefore no eye-witness of the scenes he describes. The stories themselves, a hundred in number, range from the highest pathos to the coarsest licentiousness. A creation like the patient Griselda, which international literature owes to Boccaccio, ought to atone for much that is morally and artistically objectionable in the *Decameron.* It may be said on this head, that his age and his country were not only deeply immoral, but in addition exceedingly outspoken. Moreover, his sources were anything but pure. Most of his improper stories are either anecdotes from real life, or they are taken from the *fabliaux* of mediæval French poets. On comparing the latter class of stories (about one-fifth of the whole *Decameron*) with their French originals, one finds that Boccaccio has never added to, but has sometimes toned down the revolting ingredients. Notwithstanding this, it cannot be denied that the artistic value of the *Decameron* is greatly impaired by descriptions and expressions, the intentional licentiousness of which is but imperfectly veiled by an attempt at humour.

Boccaccio has been accused of plagiarism, particularly by French critics, who correctly state that the subjects of many stories in the *Decameron* are borrowed from their literature. A similar objection might be raised against Chaucer, Shakespeare, Goethe (in *Faust*), and indeed most of the master minds of all nations. Power of invention is not the only nor even the chief criterion of a great poet. He takes his subjects indiscriminately from his own fancy, or from the consciousness of his and other nations. Stories float about in the air, known to all yet realized by few; the poet gathers their *disjecta membra* into an organic whole, and this he inspires and calls into life with the breath of his genius. It is in this sense that Boccaccio is the creator of those innumerable beautiful types and stories, which have since become household words amongst civilized nations. No author can equal him in these contributions to the store of international literature. There are indeed few great poets who have not in some way become indebted to the inexhaustible treasure of Boccaccio's creativeness. One of the greatest masterpieces of German literature, Lessing's *Nathan the Wise*, contains a story from Boccaccio (*Decameron*, Day 1st, tale iii.), and the list of English poets who have drawn from the same source comprises among many others the names of Chaucer, Lydgate, Dryden, Keats, and Tennyson.

For ten years Boccaccio continued to reside in Florence, leaving the city only occasionally on diplomatic missions or on visits to his friends. His fame in the meantime began to spread far and wide, and his *Decameron*, in particular, was devoured by the fashionable ladies and gentlemen of the age. About 1360 he seems to have retired from the turbulent scenes of Florence to his native Certaldo, the secluded charms of which he describes with rapture. In the following year took place that strange turning-point in Boccaccio's career, which is generally described as his conversion. It seems that a Carthusian monk came to him while at Certaldo charged with a posthumous message from another monk of the same order, to the effect that if Boccaccio did not at once abandon his godless ways in life and literature his death would ensue after a short time. It is also mentioned that the revelation to the friar on his deathbed of a secret known only to Boccaccio gave additional import to this alarming information. Boccaccio's impressionable nature was deeply moved. His life had been far from virtuous; in his writings he had frequently sinned against the rules of morality, and worse still, he had attacked with bitter satire the institutions and servants of holy mother church. Terrified by the approach of immediate death, he resolved to sell his library, abandon literature, and devote the remainder of his life to penance and religious exercise. To this effect he wrote to Petrarch. We possess the poet's answer; it is a masterpiece of writing, and what is more, a proof of tenderest friendship. The message of the monk Petrarch is evidently inclined

to treat simply as pious fraud, without however actually committing himself to that opinion. "No monk is required to tell thee of the shortness and precariousness of human life. Of the advice received accept what is good; abandon worldly cares, conquer thy passions, and reform thy soul and life of degraded habits. But do not give up the studies which are the true food of a healthy mind." Boccaccio seems to have acted on this valuable advice. His later works, although written in Latin and scientific in character, are by no means of a religious kind. It seems, however, that his entering the church in 1362 is connected with the events just related.

In 1363 Boccaccio went on a visit to Naples to the seneschal Acciajuoli (the same Florentine who had in 1344 persuaded the elder Boccaccio to permit his son's return to Naples), who commissioned him to write the story of his deeds of valour. On his arrival, however, the poet was treated with shameful neglect, and revenged himself by denying the possibility of relating any valorous deeds for want of their existence. This declaration, it must be confessed, came somewhat late, but it was provoked by a silly attack on the poet himself by one of the seneschal's indiscreet friends.

During the next ten years Boccaccio led an unsettled life, residing chiefly at Florence or Certaldo, but frequently leaving his home on visits to Petrarch and other friends, and on various diplomatic errands in the service of the Republic. He seems to have been poor, having spent large sums in the purchase of books, but his independent spirit rejected the numerous splendid offers of hospitality made to him by friends and admirers. During this period he wrote four important Latin works—*De Genealogia Deorum libri XV.*, a compendium of mythological knowledge full of deep learning; *De Montium, Silvarum, Lacuum, et Marium nominibus liber*, a treatise on ancient geography; and two historical books—*De Casibus Virorum et Feminarum Illustrium libri IX.*, interesting to the English reader as the original of John Lydgate's *Fall of Princes*; and *De Claris Mulieribus*. To the list of his works ought to be added *Il Ninfale Fiesolano*, a beautiful love-story in verse, and *Il Corbaccio ossia Il Laberinto d'Amore*, a coarse satire on a Florentine widow who had jilted the poet, written about 1355, not to mention many eclogues in Latin and miscellaneous *Rime* in Italian (the latter collected by his biographer Count Baldelli in 1802).

In 1373 we find Boccaccio again settled at Certaldo. Here he was attacked by a terrible disease which brought him to the verge of death, and from the consequences of which he never quite recovered. But sickness could not subdue his intellectual vigour. When the Florentines established a chair for the explanation of the *Divina Commedia* in their university, and offered it to Boccaccio, the senescent poet at once undertook the arduous duty. He delivered his first lecture on the 23d of October 1373. The commentary on part of the *Inferno*, already alluded to, bears witness of his unabated power of intellect. In 1374 the news of the loss of his dearest friend Petrarch reached Boccaccio, and from this blow he may be said to have never recovered. Almost his dying efforts were devoted to the memory of his friend; urgently he entreated Petrarch's son-in-law to arrange the publication of the deceased poet's Latin epic *Africa*, a work of which the author had been far more proud than of his immortal sonnets to Laura.

In his last will Boccaccio left his library to his father confessor, and after his decease to the convent of Santo Spirito in Florence. His small property he bequeathed to his brother Jacopo. His own natural children had died before him. He himself died on the 21st of December 1375 at Certaldo, and was buried in the church of SS. Jacopo e Filippo of that town. On his tombstone was engraved the epitaph composed by himself shortly before his death. It is calm and dignified, worthy indeed of a great life with a great purpose. These are the lines:—

> "Hac sub mole jacent cineres ac ossa Joannis;
> Mens sedet ante Deum, meritis ornata laborum
> Mortalis vitæ. Genitor Boccaccius illi;
> Patria Certaldum; studium fuit alma poesis."

A complete edition of Boccaccio's Italian writings, in 17 vols., has been published by Moutier (Florence, 1834). The life of Boccaccio has been written by Tiraboschi, Mazzuchelli, Count Baldelli (*Vita di Boccaccio*, Florence, 1806), and others. The first printed edition of the *Decameron* is without date, place, or printer's name; but it is believed to belong to the year 1469 or 1470, and to have been printed at Florence. Besides this, Baldelli mentions eleven editions during the 15th century. The entire number of editions by far exceeds a hundred. A curious expurgated edition, authorized by the Pope, appeared at Florence, 1573. Here, however, the grossest indecencies remain, the chief alteration being the change of the improper personages from priests and monks into laymen. The best old edition is that of Florence, 1527. Of modern reprints, that by Forfoni (Florence, 1857) deserves mention. Manni has written a *Storia del Decamerone* (1742), and a German scholar, M. Landau, has published (Vienna, 1869) a valuable investigation of the sources of the *Decameron*. An interesting English translation of the work appeared in 1624, under the title *The Model of Mirth, Wit, Eloquence, and Conversation.* (F. H.)

BOCCALINI, Trajano, an Italian satirist, was born at Loretto in 1556. The son of an architect, he himself adopted that profession, and it appears that he commenced late in life to apply to literary pursuits. Pursuing his studies at Rome, he had the honour of teaching Bentivoglio, and acquired the friendship of the cardinals Gaetano and Borghesi, as well as of other distinguished personages. By their influence he obtained various posts, and was even appointed by Gregory XIII. governor of Benevento in the states of the church. Here, however, he seems to have acted imprudently, and he was soon recalled to Rome, where he shortly afterwards composed his most important work, the *Ragguagli di Parnaso*, in which Apollo is represented as receiving the complaints of all who present themselves, and distributing justice according to the merits of each particular case. The book is full of light and fantastic satire on the actions and writings of his eminent contemporaries, and some of its happier hits are among the hackneyed felicities of literature. To escape, it is said, from the hostility of those whom his shafts had wounded, he returned to Venice, and there, according to the register in the parochial church of Sta Maria Formosa, died of colic, accompanied with fever, on the 16th of November 1613. It was asserted, indeed, by contemporary writers that he had been beaten to death with sand-bags by a band of Spanish bravadoes, but the story seems without foundation. At the same time, it is evident from the *Pietra del Paragone*, which appeared after his death in 1615, that whatever the feelings of the Spaniards towards him, he cherished against them feelings of the bitterest hostility. The only Government, indeed, which is exempt from his attacks is that of Venice, a city for which he seems to have had a special affection. The *Ragguagli*, which was first printed in 1612, has frequently been republished; but its popularity seems exceeded by that of the *Pietra*, which has been translated into French, German, English, and Latin. The English translator was Henry earl of Monmouth, and the title of his version, *The Politicke Touchstone*, London, 1674. Another posthumous publication of Boccalini was his *Commentarii sopra Cornelio Tacito*, Geneva, 1669, which ought rather to be called observations than commentaries, and has not done much for his fame. Many of his manuscripts are preserved still unprinted in various Italian libraries. (See Mazzuchelli's *Scrittori d'Italia*.)

BOCHART, SAMUEL, a learned writer of the 17th century, specially distinguished as an Oriental scholar, was born at Rouen in Normandy, May 30, 1599. He was many years pastor of a Protestant church at Caen, and became tutor to Wentworth Dillon, earl of Roscommon, author of the *Essay on Translated Verse.* While at Caen he particularly distinguished himself by his public disputations with Father Veron, a Jesuit, and celebrated as a polemic. The dispute was held in the castle of Caen, in the presence of a great number of Catholics and Protestants, the Duke of Longueville being among the former. In 1646 Bochart published his *Phaleg* and *Chanaan*, which are the titles of the two parts of his *Geographia Sacra.* His *Hierozoicon*, which treats of the sacred animals of Scripture, was printed at London in 1675. In 1652, Christina, queen of Sweden, invited him to Stockholm, whither he repaired, accompanied by Huet. On his return to Caen he resumed his duties as a minister of the gospel, married, and was received into the academy of that city. Bochart was a man of profound erudition; he possessed a thorough knowledge of the principal Oriental languages, including Hebrew, Syriac, Chaldaic, and Arabic; and such was his zeal for extending his acquirements, that at an advanced age he wished to learn Ethiopic. He was remarkable for modesty and candour; but so absorbed was he in his favourite study, that he saw Phœnician, and nothing but Phœnician, in everything, even in the words of the Celtic, and hence the prodigious number of chimerical etymologies which swarm in his works. He died at Caen, May 16, 1667. A complete edition of his works was published at Leyden, under the title of *Sam. Bochart Opera Omnia: hoc est; Phaleg, Chanaan, seu Geographia Sacra, et Hierozoicon, seu de Animalibus sacris Sacræ Scripturæ, et Dissertationes Variæ*, 1675, 2 vols. folio; 1692, 1712, 3 vols. folio.

BOCHNIA, the chief town of a district in Austrian Galicia, on the River Raba or Uswica, a tributary of the Vistula. It is built principally of wood, and has a gymnasium, a hospital, and various public offices. Its importance is mainly due to its extensive salt mines, entrance to which is obtained by a shaft in the very heart of the town. The excavations, carried on at different levels, have completely undermined the whole area of the place, which was greatly damaged by a subsidence of the ground in 1843, occasioned by heavy floods. About 290,000 cwts. of salt are obtained annually. Population in 1869, 7480.

BOCHUM, the chief town of a circle in the Prussian province of Westphalia and government of Arnsberg, on the railway between Duisburg and Dortmund. It is a busy industrial town, with manufactures of cassimeres, woollen cloth, carpets, and hardware of various descriptions. About 27,000 hand coffee-mills are turned out annually. There is an extensive steel factory in the hands of a company; coal-mines are worked, and coke is manufactured; and a considerable trade is carried on in grain. Population in 1871, 21,192.

BODE, JOHANN ELERT, a celebrated German astronomer, born January 19, 1747, at Hamburg, where his father kept a commercial academy. From his earliest years he was devoted to the mathematical sciences, especially astronomy. In the garret of his father's house, with the aid of a telescope constructed by himself, he eagerly made observations of the heavens; and at eighteen years of age he had acquired so great a knowledge of astronomy, that when Dr Reimarus visited his father, young Bode was found occupied in calculating an eclipse of the sun. This incident was the means of introducing him to the notice of Professor Büsch, who at once afforded him every facility for prosecuting his labours with success. Shortly afterwards Bode gave the first public proof of his knowledge by a short work on the solar eclipse of August 5, 1766; and this was followed by his *Anleitung zur Kenntniss des gestirnten Himmels*, an elementary treatise on astronomy, which was eminently successful, and has since gone through numerous editions. In 1772, being called to Berlin by Frederic II., he was made astronomer to the Academy of Sciences, and afterwards a member of that institution. The well-known periodical work entitled *Astronomische Jahrbücher*, which is continued to the present day, was commenced by Bode in 1774; but that on which his fame chiefly rests is the *Uranographia*, published in 1801, in which the industrious author has given observations of 17,240 stars, or 12,000 more than are to be found in any older charts. This veteran observer, who may justly be said to have been the first to diffuse a general taste for astronomy in Germany, died at Berlin, Nov. 23, 1826. For the curious empirical law which bears Bode's name, see ASTRONOMY, vol. ii. p. 806.

BODIN, JEAN, one of the ablest political thinkers in France during the 16th century, was born at Angers in 1530. He studied law at Toulouse, and, after taking his degree, lectured there for some time on jurisprudence. Thence he proceeded to Paris, and began to practise at the bar. His want of success is said to have been the reason of his applying himself to literature; but this we may reasonably doubt, as he was only twenty-five years of age when he published his first work, a translation of Oppian's *Cynegeticon* into Latin verse, with a commentary. Almost immediately on its publication the celebrated scholar, Turnebus, complained that some of his emendations had been appropriated without acknowledgment. A discourse on public instruction, *Oratio de Instituenda in Republica Juventute*, which Bodin had delivered at Toulouse, was printed in 1559, and his *Methodus ad Facilem Historiarum Cognitionem* appeared in 1566. The latter is a work of considerable interest and value. It has, indeed, no title to the high honour which M. Baudrillart assigns to it of having laid the foundation of the philosophy of history; but it contains several thoughts of essential importance to that philosophy, as, for example, those relative to the nature of history, to progress and law in history, and to historical causation. Two years later Bodin published a work in refutation of the views of M. de Malestroict, who maintained that there had been no rise of prices in France during the three preceding centuries. The *Responsio ad Paradoxa Malestretti* not only completely established the contrary, but for the first time explained in a nearly satisfactory manner the revolution of prices which took place in the 16th century, pointing out not only its primary but most of its secondary causes with remarkable perspicacity. This tract, the *Discours sur les causes de l'extrême cherté qui est aujourdhuy en France* (1574), and the disquisition on public revenues in the sixth book of the *Republic*, undoubtedly entitle Bodin to a distinguished position among the earlier cultivators of political economy. His learning, genial disposition, and conversational powers recommended him to the favour of Henry III. and of his brother, the duke of Alençon. The former appointed him to the office of king's attorney at Laon in 1576. This was the most eventful year of his life, being that in which he married, performed his most brilliant service to his country, and completed his greatest literary work. Elected by the Tiers État of Vermandois to represent it in the states-general of Blois, he contended with great skill and boldness in extremely difficult circumstances for freedom of conscience, justice, and peace. The nobility and clergy favoured the League, and urged the king to force his subjects to abjure Protestantism and profess the Catholic religion. When Bodin found he could not prevent this

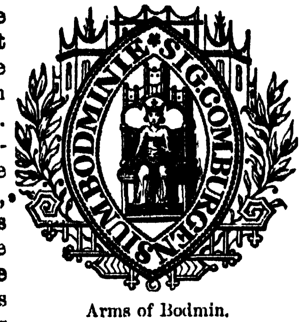
resolution being carried, he contrived to get inserted in the petition drawn up by the states the clause "without war," which practically rendered all its other clauses nugatory. While he thus resisted the clergy and nobility and their dependents, he opposed the demand of the king to be allowed to alienate the public lands and royal demesnes, and had influence sufficient to get it refused, although the chief deputies had been won over to assent to it. This lost him the favour of the king, who wanted money on any terms. His *magnum opus*—*Les six livres de la République* (Paris, 1576)—passed through various editions in its author's lifetime, that of 1583 having as an appendix *L'apologie de René Herpin* (Bodin himself). In 1586 he issued a Latin version, for the use chiefly of English students of law and politics. It is the first elaborate attempt in modern times to construct a system of political science. "From the time," says Sir William Hamilton, "when Aristotle wrote his eight books of *Politics*, until the time when Montesquieu wrote his thirty-one books on *The Spirit of Laws*, the six books of the *Republic* of Bodinus is the ablest and most remarkable treatise extant on the philosophy of government and legislation; and even until the present day these three authors stand out as the great political triumvirate." Bodin was, of course, greatly indebted to Aristotle for his knowledge of the working of political causes, but he made use of what his illustrious predecessor taught him in no servile way, and added much from his own reflections, his large acquaintance with history, and his vivid personal experience. The *Republic* is a work of which it is quite impossible to give a brief account, and as there have been many lengthened summaries of it, it may suffice to say that those to be found in Hallam's *Lit. of Europe* (vol. ii. 1st ed.), Heron's *History of Jurisprudence*, Lerminier's *Introduction à l'Histoire du Droit*, and Bluntschli's *Geschichte des Staatsrechts*, give a good general view of its character, while that in Professor Baudrillart's *J. Bodin et son Temps* is so exceedingly careful and excellent that scarcely a thought of any value in the original has escaped being indicated. With all his breadth and liberality of mind Bodin was an exceedingly credulous believer in witchcraft, the virtues of numbers, and the power of the stars, and in 1580 he published the *Demonomanie des Sorciers*, a work which is a most humbling evidence that even the greatest men may not be exempt from the most irrational prejudices of their age. Although he was himself regarded by most of his contemporaries as a sceptic, and by some as an atheist, he denounced all who dared to doubt of sorcery, and zealously urged the burning of witches and wizards. It might, perhaps, have gone hard with himself if his counsel had been strictly followed, as he confessed to have had from his thirty-seventh year a friendly demon who, if properly invoked, touched his right ear when he purposed doing what was wrong, and his left when he meditated doing good. To the duke of Alençon Bodin owed several important preferments. In 1581 he accompanied his patron as secretary when that prince came over to England to seek the hand of Queen Elizabeth. Here he had the pleasure of finding that the *Republic* was studied at London and Cambridge, although in a barbarous Latin translation. This was what determined him to translate his work into Latin himself. The latter part of Bodin's life was spent at Laon, the inhabitants of which he is said to have persuaded to declare for the League in 1589, and for Henry IV. five years afterwards. He died of the plague in that city in 1596, and was buried in the church of the Carmelites. In the year during which he died there appeared his *Universale Naturæ Theatrum*, which was translated into French by Fongerolles in the following year. He left behind him a very famous MS., the *Colloquium Heptaplomeres de abditis rerum sublimium arcanis*, which was published for the first time in a complete form by Noack in 1857, although it had been previously studied by others, *e.g.*, Grotius, Huet, Ménage, Diecmann, &c. It is composed in the form of a conversation between seven learned men—a Jew, a Mahometan, a Lutheran, a Zwinglian, a Roman Catholic, an Epicurean, and a Theist. The conclusion to which they are represented as coming is that they will live together in charity and toleration, and cease from further disputation as to religion

Authorities.—The works of Bodin above mentioned; H. Baudrillart, *J. Bodin et son Temps* (Paris, 1853); N. Planchenault, *Études sur Jean Bodin* (Angers, 1858); and Thierry, *History of the Tiers État* (Engl. Transl.) As to the political philosophy of Bodin, see the works of Hallam, Heron, Lerminier, and Bluntschli, already indicated; as to his political economy, Kautz, *Geschichte der National-Oekonomik*, ii. 269-271; as to his ethical teaching, A. Desjardins, *Les Moralistes Français du Seizième Siècle*, ch. v.; and as to his historical views, Flint's *Philosophy of History in Europe*, i. 69-76. (R. F.)

BODLEY, Sir Thomas, founder of the Bodleian library at Oxford, was born at Exeter in 1544. When he was about twelve years of age, his father, John Bodley, being obliged to leave the kingdom on account of his Protestant principles, settled with his family at Geneva, and continued there till the death of Queen Mary. In that university, then in its infancy, young Bodley studied under several eminent professors. On the accession of Queen Elizabeth he returned with his father to England, and was soon after entered of Magdalen College, Oxford. In 1563 he took the degree of bachelor of arts, and the year following was admitted a fellow of Merton College. In 1565 he read a Greek lecture in the hall of that college, took the degree of master of arts the year after, and read natural philosophy in the public schools. In 1569 he was one of the proctors of the university, and for some time after officiated as public orator. Quitting Oxford in 1576, he made the tour of Europe; and on returning to his college after four years' absence he applied himself to historical and political studies. He became gentleman-usher to Queen Elizabeth; and in 1585 he married Anne Ball, a widow lady of considerable fortune, whose father, named Carew, was of Bristol. He was soon after sent as ambassador to the king of Denmark, and to several German princes. He was next despatched on a secret mission to France; and in 1588 he went as ambassador to the United Provinces. On his return to England in 1597, finding his preferment obstructed by the jarring interests of Burleigh and Essex, he retired from court, and could never afterwards be prevailed on to accept of any public employment. He now began the foundation of the Bodleian library; and soon after the accession of King James I. he received the honour of knighthood. He died at his house in London, January 28, 1612, and was buried in the choir of Merton College chapel, where a monument of black and white marble was erected to him, on which stands his effigy in a scholar's gown, surrounded with books. Sir Thomas wrote his own life to the year 1609, which, with the first draught of the Statutes and his Letters, has been published from the originals in the Bodleian library, by Hearn, under the title of *Reliquiæ Bodleianæ, or Authentic Remains of Sir Thomas Bodley*, London, 1793, 8vo. For a particular account of the Bodleian library, see Libraries.

BODMIN, a parliamentary and municipal borough and market-town of England, in the county of Cornwall, 235 miles from London, and 30 from Plymouth by rail. It is situated between two hills, and consists of one narrow but well-paved street, about a mile in length. The church of St Petrock, which formerly belonged to the monastery of that name, is a spacious building dating from 1472; and the town-hall consists partly of remains of the convent of the Grey Friars. A lunatic asylum, erected in 1866, the

county jail, rebuilt in 1859, and a market-house of recent date, are among the chief buildings. The principal manufacture is shoes. Four annual fairs for cattle and horses are held in the town, and at St Lawrence, one mile to the S.W., there is a fair in October for cattle and sheep. Bodmin returned two members to Parliament from the time of Edward I. till 1868, when its representation was reduced to one member. The assizes and quarter-sessions are held in the town, and it is one of the polling-places for the east division of the county. Bodmin or, as the name appears in charters, *Bosmana* or *Bod-minian*, grew up in the neighbourhood of a monastic building, which is said to have been founded as early as 926. At the time of the Conquest it was a flourishing town, but fell into decay at the Reformation, and only recovered its prosperity in the course of last century. In 1498 the Cornish insurrection was originated by the people of Bodmin, who again, in the reign of Edward VI., expressed their discontent at the change of religion by resorting to arms. Population of municipal borough in 1871, 4672, and of parliamentary borough, 6758.



Arms of Bodmin.

BODONI, GIAMBATTISTA, superintendent of the royal press at Parma, chief printer to his Catholic Majesty, member of various academies in Italy, and knight of several orders, was born in 1740, at Saluzzo in Piedmont, where his father owned a printing establishment. While yet a boy he began to engrave on wood. He at length went to Rome, and there became a compositor for the press of the Propaganda. He made himself acquainted with the Oriental languages, and thus was enabled to render essential service to the Propaganda press, by restoring and accurately distributing the types of several Oriental alphabets which had fallen into disorder. The Infante Don Ferdinand having established at Parma, about 1760, a printing-house on the model of those in Paris, Madrid, and Turin, Bodoni was placed at the head of this establishment, which he soon rendered the first of the kind in Europe. The beauty of his typography, &c., leaves nothing further to be desired; but the intrinsic value of his editions is seldom equal to their outward splendour. His Homer, however, is a truly magnificent work; and, indeed, his Greek letters are faultless imitations of the best Greek manuscript. His editions of the Greek, Latin, Italian, and French classics are all highly prized for their typographical elegance, and some of them are not less remarkable for their accuracy. Bodoni died at Padua in 1813, aged 73. In 1818 a magnificent work appeared in two volumes quarto, entitled *Manuale Tipografico*, containing specimens of the vast collection of types which had belonged to this celebrated typographer. See De Lama, *Vita del Cavaliere Giambattista Bodoni*, 1816, 2 vols.

BOECE, or BOYCE, HECTOR, a distinguished Scottish historian, was born at Dundee, about the year 1465, being descended of a family which for several generations had possessed the barony of Panbridge or Balbridge. The orthography of his surname is extremely fluctuating; it is to be found under the various modifications of Boece, Boeth, Boeis, Boys, Boyse, Boyes, Boyis, Boiss, and Boyce. He received his early education at Dundee, and completed his course of study in the university of Paris, where he took the degree of B.D. He was appointed a professor of philosophy in the college of Montaigu; and in this seminary he became intimately acquainted with Erasmus, who in two epistles has testified his esteem for Boece's character (*Erasmi Opera*, tom. i. tom. iii. col. 1784, edit. Clerici). In his academical station he had already distinguished himself when King's College was founded at Aberdeen by the munificence of William Elphinstone, bishop of the diocese. The Papal bull for the erection of a university had been obtained in the year 1494, but the buildings were not sufficiently advanced, nor did the lectures commence, till about the year 1500. It was not without some degree of hesitation that he consented to quit the lettered society of Paris, and to become principal of this new college; but having at length accepted the conditions, he proceeded to Aberdeen, and experienced a kind reception from the canons of the cathedral, several of whom he has commemorated as men of learning. It was a part of his duty as principal to read lectures on divinity. The common branches of science and literature were taught with zeal and success; and the prosperity of the institution was greatly promoted by the influence of Boece.

The emoluments of his office were not such as appear very dazzling to modern eyes. "Boethius, as president of the university," says Dr Johnson, "enjoyed a revenue of forty Scottish marks, about two pounds four shillings and sixpence of sterling money. In the present age of trade and taxes, it is difficult even for the imagination so to raise the value of money, or so to diminish the demands of life, as to suppose four and forty shillings a year an honourable stipend; yet it was probably equal not only to the needs but to the rank of Boethius. The wealth of England was undoubtedly to that of Scotland more than five to one, and it is known that Henry the Eighth, among whose faults avarice was never reckoned, granted to Roger Ascham, as a reward of his learning, a pension of ten pounds a year." But it is necessary to recollect that this was not the only preferment which Boece enjoyed: he was not only principal of King's College, but was likewise a canon of Aberdeen, and rector of Tyrie in the same county. Under the date of July 14, 1527, we find a "grant to Maister Hector" of an annual pension of £50, to be paid by the sheriff of Aberdeen out of the king's casualties; and on the 26th of July 1529 was issued a "precept for a lettre to Mr Hector Boys, professor of theology, of a pension of £50 Scots yearly, until the king promote him to a benefice of 100 marks Scots of yearly value; the said pension to be paid him by the customers of Aberdeen." In 1533 and 1534, one-half of his pension was, however, paid by the king's treasurer, and the other half by the comptroller; and as no payment subsequent to that of Whitsuntide 1534 has been traced in the treasurer's accounts, he is supposed to have obtained his benefice soon after that period.

His earliest publication, the lives of the bishops of Aberdeen, appeared under the following title—*Episcoporum Murthlacensium et Aberdonensium per Hectorem Boetium Vitæ. Impressa sunt hæc prelo Ascensiano ad Idus Maias anno Salutis, M.D.XXII* 4to. This little volume, which is of great rarity, was reprinted for the members of the Bannatyne Club—*Hectoris Boetii Murthlacensium et Aberdonensium Episcoporum Vitæ iterum in lucem editæ*, Edin., 1825, 4to. Of this diocese the seat was originally at Murthlack, or Mortlach, in the county of Banff, but it was afterwards transferred to Aberdeen. His notices of the early prelates are necessarily brief and unsatisfactory, and the most interesting portion of the book is that which relates to his liberal patron Bishop Elphinstone, of whose private history and public services he has given a circumstantial detail, which occupies nearly one-third of the volume. Here we likewise find an account of the foundation and constitution of the college, together with some notices of its earliest members. His more famous work, the *History of Scotland*, was published after an interval of

five years:—*Scotorum Historiæ a prima gentis origine cum aliarum et rerum et gentium illustratione non vulgari: præmissa epistola nuncupatoria, tabellisque amplissimis, et non pœnitenda Isagoge, quæ ab hujus tergo explicabitur diffusius. Quæ omnia impressa quidem sunt Iodoci Badii Ascensii typis et opera; impensis autem nobilis et prædocti viri Hectoris Boethii Deidonani, a quo sunt et condita et edita*, fol. The title and colophon have no date, but the commendatory epistle by Alexander Lyon, precentor of the cathedral of Elgin, bears the 15th of March 1527. This edition contains seventeen books. Another edition, containing the eighteenth book and a fragment of the nineteenth, was published by Ferrerius, who has added an appendix of thirty-five pages; Paris, 1574, fol. Though published at Paris, the latter edition appears from the colophon to have been printed at Lausanne.

The composition of Boece's history displays much ability; and if the style does not always reach the standard of ancient purity, it displays a certain vein of elegance which generally renders it attractive. The author's love of his native country, and his anxiety to emblazon the heroic deeds of his countrymen, are conspicuous in every part of the work; nor must we leave unnoticed those aspirations after political freedom, by which he was honourably distinguished at a period when the human mind was so generally chained to the earth by the most slavish maxims of submission. It may be recorded as commendation instead of reproach, that his principles of polity have been represented as no better than those of Buchanan. Boece's imagination was, however, stronger than his judgment: of the extent of the historian's credulity, his narrative exhibits many unequivocal proofs; and if this circumstance admits of a sufficient excuse from the common propensity of the age in which he lived, his work presents strong indications of another fault, for which it is not so easy to find an apology. According to Bishop Lloyd, he put Fordun's tales "into the form of an history, and pieced them out with a very good invention, that part in which he chiefly excelled." (Lloyd's *Historical Account of Church Government in Great Britain and Ireland*, pref.) He professes to have obtained from the monastery of Icolmkill, through the good offices of the earl of Argyll, and his brother the treasurer, certain original historians of Scotland, and among the rest Veremundus and Campbell, of whose writings not a single vestige is now to be found. In his dedication to the king, he is pleased to state that Veremundus, a Spaniard by birth, was archdeacon of St Andrews, and that he wrote in Latin a history of Scotland from the origin of the nation to the reign of Malcolm III., to whom he inscribed his work. According to Bishop Stillingfleet, whose opinion has been adopted by many other writers, these historians never existed except in Boece's fertile imagination. His propensity to the marvellous was at an early period exposed in the following tetrastich of Leland:—

> "Hectoris historici tot quot mendacia scripsit,
> Si vis ut numerem, lector amice, tibi,
> Me jubeas etiam fluctus numerare marinos,
> Et liquidi stellas connumerare poli."

Lhuyd, who attacked him in different works, spoke of his fabrications with unsparing severity, nor did he experience much better treatment from Stanihurst, an Irish writer of considerable reputation. Of his merits as an historian a very unfavourable estimate was formed by Lord Hailes and Mr Pinkerton. But in the opinion of Wallace, a learned lawyer, his "elegant style and correct composition, not to add beautiful genius and fine fancy, are conclusive proofs that his understanding could not be inaccurate." And, as Maitland, the editor of Bellenden's translation of Boece's history, has remarked, "in forming a final estimate of the literary character of Boece, we must bear in mind that, when scholar-craft in this country at least was rare, he was a scholar, and contributed, by reviving ancient learning, to dispel the gloom of the Middle Ages; and that, while the history of his country existed only in the rude page of the chroniclers who preceded him, or in the fading records of oral tradition, he embodied it in narrative so interesting and language so beautiful, as to be worthy of a more refined age."

Boece's *History of Scotland* was translated into the Scottish language by John Bellenden, archdeacon of Moray and canon of Ross. While the learned archdeacon was engaged in translating the work into prose, another individual was engaged in the more formidable task of translating it into verse. A copy of this metrical version, containing about 70,000 lines, is preserved in the library of the University of Cambridge; a leaf seems to be wanting at the beginning, and the manuscript has suffered some other mutilations. The name of the versifier does not appear, nor has it been ascertained from any other document; but we learn from the prologue that his labours, like those of Bellenden, were intended for the benefit of the young monarch. From the concluding lines, it is ascertained that he began his task in April 1531, and concluded it in September 1535. His verses are not distinguished by any considerable degree of energy or elegance, and the writer is chiefly to be commended for his perseverance.

In 1528, soon after the publication of his history, Boece took the degree of D.D. at Aberdeen; and on this occasion the magistrates voted him a present of a tun of wine when the new wines should arrive, or, according to his option, the sum of £20 to purchase a new bonnet. He appears to have survived till the year 1536; for on the 22d of November in that year, the king presented John Garden to the rectory of Tyrie, vacant by the death of "Mr Hector Boiss." He died at Aberdeen, and, according to the most probable conjecture, he had then attained, or at least approached, the age of seventy.

BOECKH, AUGUST, one of the greatest scholars that Germany has produced in modern times, was born in Karlsruhe, November 24, 1785. He was sent to the gymnasium of his native city, and remained there until he left for the University of Halle. There he devoted himself to the study of theology, as his intention was to enter the church. He had the privilege of listening to the lectures of Schleiermacher and other eminent theologians; but at this time in Halle F. Wolf was exercising a spell over the young men and creating an enthusiasm for classical studies. August Boeckh felt the spell, passed from theology to philology, and became the greatest of all Wolf's scholars. At Easter of 1806 he went to Berlin to study in the seminary for secondary teachers, conducted by Gedike; but the disturbances which then agitated the country sent him home. In the summer of 1807 he came out as privat-docent in the University of Heidelberg, and in the autumn of the same year he was appointed a professor extraordinarius. Two years after (1809) he was nominated ordinary professor. In 1811 he removed to Berlin, having been appointed professor of eloquence and ancient literature in the university newly established there. Here he remained till his death, which took place August 3, 1867. He was elected a member of the Academy of Sciences of Berlin in 1814, and for a long time acted as its secretary. Many of the speeches contained in his *Kleine Schriften* were delivered in this latter capacity.

Boeckh worked out the ideas of Wolf in regard to philology, and illustrated them by his practice. Discarding the old notion that philology lay in a minute acquaintance with words and the exercise of the critical art, he believed it to be the entire knowledge of antiquity, historical and philosophical (*esse eam universæ antiquitatis cognitionem*

historicam et philosopham). He divides philology into five parts: first, an inquiry into public acts, with a knowledge of times and places, into civil institutions, and also into law; second, an inquiry into private affairs; third, an exhibition of the religions and arts of the ancient nations; fourth, a history of all their moral and physical speculations and beliefs, and of their literatures; and fifth, a complete explanation of the language. These ideas in regard to philology Boeckh gave out in a Latin oration delivered in 1822 (*Gesammelte Kleine Schriften*, vol. i. p. 104). He repeats them in somewhat different language in the speech which he delivered at the opening of the congress of German philologists in 1850. He there defines philology to be the historical construction of the entire life,—therefore, of all forms of culture and all the productions of a people in its practical and spiritual tendencies. He allows that such a work is too great for any one man; but the very infinity of subjects is the stimulus to the pursuit of truth, and men strive because they have not attained (vol. ii. p. 189). Even before Boeckh had published anything on this subject, his oral expositions had become widely spread, and were much discussed. (Lübker, "De Partitione Philologiæ," *Gesammelte Schriften zur Philologie und Pædogogik*, vol. i. p. 8.) Freund gives the following account of Boeckh's division of philology:—

"Boeckh distinguishes two chief parts of philological discipline—a formal and a material part. To the formal part belong only interpretation and criticism; to the material all the other disciplines, even grammar. More particularly the material part embraces—I. the practical life; II. the theoretical life of the ancients. I. The practical, again, falls into the two divisions of—1. Public life, including (1) political history, (2) political antiquities, (3) chronology, and (4) geography; 2. Private life, which is considered as (1) external life, in agriculture, commerce, trades, domestic economy, and metrology; (2) internal life, including marriage, education, slaves, &c. II. Theoretical life is divided into two parts—1. The life in which the thought of man is presented externally through a symbol—worship, plastic art, music, *Orchestik*; 2. Life in which the thought remains pure within the mind—science. In the case of the last (1) the contents, and (2) the form of acquisition are distinguished. The contents lie originally in mythology, out of which philosophy developed itself, and out of philosophy came the other sciences, which are partly physical, including mathematics, and partly ethical. The form of knowledge is language, and it must be considered first in itself, in its inner structure through grammar, and then in its formation and application to the various artistic forms which the history of literature has to exhibit" (*Wie studirt man Philologie*, p. 29).

From 1806 till the time of his death, Boeckh's literary activity was unceasing. His principal works were—(1.) An edition of Pindar, the first volume of which (1811) contains the text of the Epinician odes; a treatise *De Metris Pindari*, in three books; and *Notæ Criticæ:* the second (1819) contains the *Scholia;* and part ii. of volume ii. (1821) contains a Latin translation, a commentary, the fragments, and indices. It is the most complete edition of Pindar that we have. But it was especially the treatise *De Metris Pindari* in the first volume which placed Boeckh in the first rank of scholars. This treatise forms an epoch in the treatment of Greek metres. In it the author threw aside all attempts to determine the Greek metres by mere subjective standards, pointing out at the same time the close connection between the music and the poetry of the Greeks. He investigated minutely the nature of Greek music as far as it can be ascertained, as well as all the details regarding Greek musical instruments; and he explained the statements of the ancient Greek writers on rhythm. In this manner he laid the foundation for a new treatment of Greek metres. (2.) *Die Staatsaushaltung der Athener*, 2 vols., Berlin, 1817 (2d improved edition, Berlin, 1851), translated into English by Sir George Cornewall Lewis, 2 vols., Lond., 1828. Boeckh shows in this work an imperfect acquaintance with the principles of the modern science of political economy. The book might have been written by an ancient Greek. But this imperfection does not much impair its great value and extraordinary merits. Boeckh has in it investigated a subject of peculiar difficulty with profound learning. He has amassed information from the whole range of Greek literature, he has carefully apprized the value of the information given, and he shows throughout every portion of it rare critical ability and insight. Similar and supplementary to his work on the political economy of Athens, was his *Urkunden über das Seewesen des Attischen Staats*, Berlin, 1840. Allied to it also was his work *Metrologische Untersuchungen über Gewichte, Münzfusse, und Maasse des Alterthums*, Berlin, 1838. (3.) His third great work arose out of his second. In regard to the taxes and revenue of the Athenian state he derived a great deal of his most trustworthy information from inscriptions, and many of these inscriptions are given in his book. It was natural, therefore, that when the Berlin Academy of Sciences projected the plan of a *Corpus Inscriptionum Græcarum*, Boeckh should be chosen as the principal editor. This great work (1825-1859) is in four volumes, the last being incomplete. Boeckh's resources as a scholar have full scope in the treatment of these inscriptions, and though a new edition is now necessary and has been begun, Boeckh's explanations of them will form the basis of all subsequent commentaries.

These were Boeckh's great works; but his activity was continually digressing into widely different fields. He has gained for himself a foremost position amongst investigators into ancient chronology, and his name will occupy a parallel place with those of Ideler and Mommsen. His principal work on this subject was called *Zur Geschichte der Mondcyclen der Hellenen*, Leipsic, 1855; but another, *Epigraphisch-chronologische Studien*, 1856, and several papers which he published in the *Transactions of the Berlin Academy*, throw light on the subject. Boeckh also occupied himself with philosophy. One of his earliest papers was on the Platonic doctrine of the world (*De Platonica corporis mundani fabrica*, 1809), and *De Plat. System. cœlestium globorum et de versa indole astronomiæ Philolaicæ*, 1810. In opposition to Gruppe he denied that Plato affirmed the diurnal rotation of the earth, *Untersuchungen uber das kosmische System des Platon*, Berlin, 1852, and when in opposition to him Grote published his opinions on the subjects (Plato and the Rotation of the Earth) Boeckh was ready with his reply. Another of his earlier papers, and one frequently referred to, was *Commentatio Academica de simultate quæ Platoni cum Xenophonte intercessisse fertur* (1811).

Boeckh did not do much in the way of editing the classics. We have already noticed his edition of Pindar. He also published an edition of the Antigone of Sophocles, with a poetical translation. (*Antigone, Griechisch und Deutsch: Nebst Abhandlungen über diese Tragödie in Ganzen und über Einzelne Stellen derselben*, Berlin, 1843). He also collected and arranged the fragments ascribed to Philolaus (Berlin, 1819), and endeavoured to show that they were genuine. The force of his arguments in this direction has, however, been recently weakened by Schaarschmidt, and the genuineness of the fragments is open to grave doubt.

The smaller writings of Boeckh began to be collected in his lifetime. Three of the volumes were published before his death, and four after (*Gesammelte kleine Schriften*, 7 vols., 1859–1873). The first two consist of orations

delivered in the university or academy of Berlin, or on public occasions. The third, fourth, fifth, and sixth contain his contributions to the *Transactions of the Berlin Academy*, and the seventh contains his critiques. The first two are valuable among other excellences from an educational point of view, and contain an exposition of many sound educational principles. In them Boeckh shows himself a man of wide heart, interested in the most diverse forms of investigation, an ardent patriot, and a lover of justice and truth. (J. D.)

BOEHME, JAKOB (1575–1624), a mystical writer, whose surname (of which Fechner gives eight German varieties) appears in English literature as Beem, Behmont, &c., and notably in the form BEHMEN, was born at Alt-Seidenberg, in Upper Lusatia, a straggling hamlet among the hills, some ten miles S.E. of Gorlitz. He came of a well-to-do family, but his first employment was that of herd boy on the Landskrone, a hill in the neighbourhood of Görlitz, and the only education he received was at the town-school of Seidenberg, a mile from his home. Seidenberg, to this day, is filled with shoemakers, and to a shoemaker Jakob was apprenticed in his fourteenth year (1589), being judged not robust enough for husbandry. Ten years later (1599) we find him settled at Görlitz as master-shoemaker, and married to Katharina, daughter of Hans Kuntzschmann, a thriving butcher in the town. After industriously pursuing his vocation for ten years, he bought (1610) the substantial house, which still preserves his name, close by the bridge, in the Neiss-Vorstadt. Two or three years later he gave up business, and did not resume it as a shoemaker; but for some years before his death he made and sold woollen gloves, regularly visiting Prague fair for this purpose.

Boehme's authorship began in his 37th year (1612) with a treatise, *Morgen Röthe im Auffgang*, which though unfinished was surreptitiously copied, and eagerly circulated in MS. by Karl von Ender. This raised him at once out of his homely sphere, and made him the centre of a local circle of liberal thinkers, considerably above him in station and culture. The charge of heresy was, however, soon directed against him by Gregorius Richter, then pastor primarius of Gorlitz. Feeling ran so high after Richter's pulpit denunciations, that, in July 1613, the municipal council, fearing a disturbance of the peace, made a show of examining Boehme, took possession of his fragmentary quarto, and dismissed the writer with an admonition to meddle no more with such matters. For five years he obeyed this injunction. But in 1618 began a second period of authorship; he poured forth, but did not publish, treatise after treatise, expository and polemical, in the next and the two following years. In 1622 he composed nothing but a few short pieces on true repentance, resignation, &c., which, however, devotionally speaking, are the most precious of all his writings. They were the only pieces offered to the public in his lifetime and with his permission, a fact which is evidence of the essentially religious and practical character of his mind. Their publication at Gorlitz, on New Year's Day 1624, under the title of *Der Weg zu Christo*, was the signal for renewed clerical hostility. Boehme had by this time entered on the third and most prolific though the shortest period (1623–4) of his speculation. His labours at the desk were interrupted in May 1624 by a summons to Dresden, where his famous "colloquy" with the Upper Consistorial Court was made the occasion of a flattering but transient ovation on the part of a new circle of admirers. Richter died in August 1624, and Boehme did not long survive his pertinacious foe. Seized with a fever when away from home, he was with difficulty conveyed to Görlitz. His wife was at Dresden on business; and during the first week of his malady he was nursed by a literary friend. He died, after receiving the rites of the church, grudgingly administered by the authorities, on Sunday, 17th November. Clerical ill-will followed him to the grave, and the malice of the vulgar defaced his monument.

Boehme always professed that a direct inward opening or illumination was the only source of his speculative power. He pretended to no other revelation. Ecstatic raptures we should not expect, for he was essentially a Protestant mystic. No "thus saith the Lord" was claimed as his warrant, after the manner of Antoinette Bourignon, or Ludowick Muggleton; no spirits or angels held converse with him as with Swedenborg. It is needless to dwell, in the way either of acceptance or rejection, on the very few occasions in which his outward life seemed to him to come into contact with the invisible world. The apparition of the pail of gold to the herd boy on the Landskrone, the visit of the mysterious stranger to the young apprentice, the fascination of the luminous sheen, reflected from a common pewter dish, which first, in 1600, gave an intuitive turn to his meditations, the heavenly music which filled his ears as he lay dying—none of these matters are connected organically with the secret of his special power. The mysteries of which he discoursed were not reported to him: he "beheld" them. He saw the root of all mysteries, the *Ungrund* or *Urgrund*, whence issue all contrasts and discordant principles, hardness and softness, severity and mildness, sweet and bitter, love and sorrow, heaven and hell. These he "saw" in their origin; these he attempted to describe in their issue, and to reconcile in their eternal result. He saw into the being of God; whence the birth or going forth of the divine manifestation. Nature lay unveiled to him, he was at home in the heart of things. "His own book, which he himself was," the microcosm of man, with his threefold life, was patent to his vision. Such was his own account of his qualification. If he failed it was in expression; he confessed himself a poor mouthpiece, though he saw with a sure spiritual eye.

It must not be supposed that the form in which Boehme's pneumatic realism worked itself out in detail was shaped entirely from within. In his writings we trace the influence of Theophr. Bombast von Hohenheim, known as Paracelsus (1493–1541), of Kaspar Schwenkfeld (1490–1561), the first Protestant mystic, and of Valentin Weigel (1533–1588). From the school of Paracelsus came much of his puzzling phraseology,—his *Turba* and *Tinctur* and so forth,—a phraseology embarrassing to himself as well as to his readers. His friends plied him with foreign terms, which he was delighted to receive, interpreting them by an instinct, and using them often in a corrupted form and always in a sense of his own. Thus the word *Idea* called up before him the image of "a very fair, heavenly, and chaste virgin." The title *Aurora*, by which his earliest treatise is best known, was furnished by Dr Balthasar Walther. These, however, were false helps, which only serve to obscure a difficult study, like the *Flagrat* and *Lubet*, with which his English translator veiled Boehme's own honest *Schreck* and *Lust*. There is danger lest his crude science and his crude philosophical vocabulary conceal the fertility of Boehme's ideas and the transcendent greatness of his religious insight. Few will take the pains to follow him through the interminable account of his seven *Quellgeister*, which remind us of Gnosticism; or even of his three first properties of eternal nature, in which his disciples find Newton's formulæ anticipated, and which certainly bear a marvellous resemblance to the three ἀρχαί of Schelling's *Theogonische Natur*. Boehme is always greatest when he breaks away from his fancies and his trammels, and allows speech to the voice of his heart. Then he is artless, clear, and strong; and no man can help listening to him, whether he dive deep down with the

conviction "ohne Gift und Grimm kein Leben," or rise with the belief that "the being of all beings is a wrestling power," or soar with the persuasion that Love "in its height is as high as God." The mystical poet of Silesia, Joh. Angelus, discerned where Boehme's truest power lay when he sang—

"Im Wasser lebt der Fisch, die Pflanze in der Erden,
Der Vogel in der Luft, die Sonn' am Firmament,
Der Salamander muss im Feu'r erhalten werden,
Und Gottes Herz ist Jakob Bohme's Element."

The three periods of Boehme's authorship constitute three distinct stages in the development of his philosophy. He himself marks a threefold division of his subject matter:—1. PHILOSOPHIA, *i.e.*, the pursuit of the divine *Sophia*, a study of God in himself; this was attempted in the *Aurora*. 2. ASTROLOGIA, *i.e.*, in the largest sense, cosmology, the manifestation of the divine in the structure of the world and of man; hereto belong, with others, *Die drei Principien göttlichen Wesens; Vom dreifachen Leben der Menschen; Von der Menschwerdung Christi; Von der Geburt und Bezeichnung aller Wesen* (known as *Signatura Rerum*). 3. THEOLOGIA, *i.e.*, in Scougall's phrase, "the life of God in the soul of man." Of the speculative writings under this head the most important are *Von der Gnadenwahl; Mysterium Magnum* (a spiritual commentary on Genesis); *Von Christi Testamenten* (the Sacraments).

Although Boehme's philosophy is essentially theological, and his theology essentially philosophical, one would hardly describe him as a philosophical theologian; and, indeed, his position is not one in which either the philosopher or the theologian finds it easy to make himself completely at home. The philosopher finds no trace in Boehme of a conception of God which rests its own validity on an accord with the highest canons of reason or of morals; it is in the actual not in the ideal that Boehme seeks God, whom he discovers as the spring of natural powers and forces, rather than as the goal of advancing thought. The theologian is staggered by a language which breaks the fixed association of theological phrases, and strangely reversing the usual point of view, characteristically pictures God as underneath rather than above. Nature rises out of Him; we sink into Him. The *Ungrund* of the unmanifested Godhead is boldly represented in the English translations of Boehme by the word *Abyss*, in a sense altogether unexplained by its Biblical use. In the *Theologia Germanica* this tendency to regard God as the *substantia*, the underlying ground of all things, is accepted as a foundation for piety; the same view, when offered in the colder logic of Spinoza, is sometimes set aside as atheistical. The procession of spiritual forces and natural phenomena out of the *Ungrund* is described by Boehme in terms of a threefold manifestation, commended no doubt by the constitution of the Christian Trinity, but exhibited in a form derived from the school of Paracelsus. From Weigel he learned a purely idealistic explanation of the universe, according to which it is not the resultant of material forces, but the expression of spiritual principles. These two explanations were fused in his mind till they issued forth as equivalent forms of one and the same thought. Further, Schwenkfeld supplied him with the germs of a transcendental exegesis, whereby the Christian Scriptures and the dogmata of Lutheran orthodoxy were opened up in harmony with his new-found views. Thus equipped, Boehme's own genius did the rest. A primary effort of Boehme's philosophy is to show how material powers are substantially one with moral forces. This is the object with which he draws out the dogmatic scheme which dictates the arrangement of his seven *Quellgeister*. Translating Boehme's thought out of the uncouth dialect of material symbols (as to which one doubts sometimes whether he means them as concrete instances, or as pictorial illustrations, or as a mere *memoria technica*) we find that Boehme conceives of the correlation of two triads of forces. Each triad consists of a thesis, an antithesis, and a synthesis; and the two are connected by an important link. In the hidden life of the Godhead, which is at once *Nichts* and *Alles*, exists the original triad, viz., Attraction, Diffusion, and their resultant, the Agony of the unmanifested Godhead. The transition is made; by an act of will the divine Spirit comes to Light; and immediately the manifested life appears in the triad of Love, Expression, and their resultant, Visible Variety. As the action of contraries and their resultant are explained the relations of soul, body, and spirit; of good, evil, and free will; of the spheres of the angels, of Lucifer, and of this world. It is a more difficult problem to account on this philosophy for the introduction of evil. Boehme does not resort to dualism, nor has he the smallest sympathy with a pantheistic repudiation of the fact of sin. That the difficulty presses him is clear from the progressive changes in his attempted solution of the problem. In the *Aurora* nothing save good proceeds from the *Ungrund*, though there is good that abides and good that falls—Christ and Lucifer. In the second stage of his writing the antithesis is directly generated as such; good and its contrary are coincidently given from the one creative source, as factors of life and movement; while in the third period evil is a direct outcome of the primary principle of divine manifestation—it is the wrath side of God. Corresponding to this change we trace a significant variation in the moral end contemplated by Boehme as the object of this world's life and history. In the first stage the world is created in remedy of a decline; in the second, for the adjustment of a balance of forces; in the third, to exhibit the eternal victory of good over evil, of love over wrath.

Boehme's influence has lain chiefly with the learned. Translations of sundry treatises have been made into Latin (by J. A. Werdenhagen, 1632), Dutch (complete, by W. v. Bayerland, 1634–41), and French (by Jean Macle, *circ.* 1640, and L. C. de Saint-Martin, 1800–9). For the nearest approach to popularity which his writings have enjoyed we must search the annals of the English Commonwealth. Between 1644 and 1662, all Boehme's works were translated by John Ellistone (d. 1652) and John Sparrow, assisted by Durand Hotham and Humphrey Blunden, who paid for the undertaking. At that time regular societies of *Behmenists*, embracing not only the cultivated but the vulgar, existed in England and in Holland. They merged into the Quaker movement, holding already in common with Friends that salvation is nothing short of the very presence and life of Christ in the believer, and only kept apart by an objective doctrine of the sacraments which exposed them to the polemic of Quakers (*e.g.*, J. Anderdon). Muggleton led an anthropomorphic reaction against them, and between the two currents they were swept away. The Philadelphian Society at the beginning of the 18th century consisted of cultured mystics, Jane Lead, Pordage, Francis Lee, Bromley, &c., who fed upon Boehme. William Law (1686–1761) somewhat later recurred to the same spring, with the result, however, in those dry times of bringing his own good sense into question rather than of reviving the credit of his author. After Law's death the old English translation was in great part re-edited (4 vols. 1762–84) as a tribute to his memory, by George Ward and Thomas Langcake, with plates from the designs of D. A. Freher (Brit. Mus. *Add. MSS.* 5767–94). This forms what is commonly called Law's translation; to complete it a 5th vol. (12mo, Dublin, 1820) is needed. Germany has also in this century turned to Boehme with eyes directly philosophical. "He is known," says Hegel, "as the *Philosophus Teutonicus*; and in reality through him for the first time did philosophy in Germany come forward with a characteristic stamp. The kernel of his philosophizing is purely German" (*Gesch. Ph.*, iii. 1836, p. 300). Franz Baader is the most remarkable of his recent philosophical exponents. See also Hamberger, *Die Lehre des deutschen Philosophen J. Boehmes*, 1844; Alb. Peip, *J. Boehme der deutsche Philosoph*, 1860; von Harless, *J. Boehme und die Alchymisten*, 1870. For Boehme's life, consult the *Memoirs*, by Abm. von Frankenberg and others, trans. by Fras. Okely, 1870; La Motte-Fouqué's *J. Boehm, ein biographischer Denkstein*, 1831; and, above all, H. A. Fechner's *J. Böhme, sein Leben und seine Schriften*, 1857. A comprehensive study of Boehme in English is a desideratum. See *Memorial of W. Law* (by Chr. Walton, 1856); *Sat. Rev.*, xxxvi.

(1878) p. 52; *Unitar. Rev.* (*Amer.*), ii. (1874) pp. 243, 447, art. by Prof. R. E. Thomson. Boehme's MSS. went to Holland. His works, having been separately printed at Amsterdam, 1631–82, by Hen. Beets and others, were first uniformly edited by J. G. Gichtel, Amst. 1682–3, in 24 pts. 8vo, bound in 6, 7, or 9 vols.; reprinted Amst. 1715, 2 vols. 4to; again, Amst. 1730–1, in 21 pts. 8vo, bound in 6 vols. They were re-edited by K. W. Schiebler, Leips. 1831–47, in 7 vols. 8vo; reprinted 1861, *ff.*

BŒOTIA (Βοιωτία) a country of Central Greece, bounded on the S. by the Gulf of Corinth, Megaris, and Attica; on the E. by Attica and the Euripus, which separates it from Eubœa; on the N. by the territory of the Locri Opuntii; and on the W. by Phocis. Its surface is estimated at 1119 English square miles. Surrounded nearly on all sides by mountains, it divides itself naturally into three parts, the low country about Lake Copais, or, as it is now called, the Lake of Topolias, the valley of the River Asopus (now Oropo), and the coast district between Mount Helicon and the Corinthian Gulf. The country about the lake is a large valley, so completely surrounded by hills that it is connected with the Eubœan Sea by subterranean passages only. The natural passages, or *katavothra*, not being sufficient to carry off the great masses of water accumulating in the valley, which is traversed by the Cephisus, the principal river in the country, the early inhabitants often suffered severely from inundations; and at a very remote period large artificial drains were constructed, probably by the Minyans of Orchomenos, to supplement the natural outlets. Remains of these works, as stupendous as any that were executed in antiquity, still excite the admiration of the traveller. They formerly rendered that part of Bœotia one of the most fertile districts of Greece, but being neglected for centuries, the shores of the lake became an extensive marsh. A large stretch of country is still often under water during the winter, but it begins to dry up in spring, and in summer forms fine wheat-fields and meadows. Between this valley of the Copais and the basin of the Asopus is situated the Theban plain, which is still distinguished for its fertility, especially in grain. The lowlands and valleys of Bœotia were notorious in antiquity for their moist and thick atmosphere, which was believed to render the inhabitants dull and stupid. For these characteristics the Bœotians are frequently satirized by the Attic writers; and it is certain that comparatively few names were added to the long roll of Greek literature from this portion of the Greek soil. One writer alone, perhaps, the poet Pindar, stands out in striking contrast to the national character; the two others who alone of his fellow-countrymen can claim to be also his intellectual kinsmen, Hesiod and Plutarch, bear no small trace of a Bœotian origin. The dialect spoken by the Bœotians was a broad Æolic. In the earliest times of history Bœotia was inhabited by various tribes, such as the Aonians, Temmicians, Thracians, Leleges, Phlegyans, and the Minyans of Orchomenos. Of these we know almost nothing, but the last-mentioned appear to have formed a great centre of civilization at a very remote period. All these tribes were gradually expelled or absorbed by the Bœotian Æolians, who immigrated from Thessaly about sixty years after the destruction of Troy, according to the ordinary chronology. The country, which had previously possessed no common name, henceforth is always spoken of as Bœotia, and the several cities and towns, with Thebes at their head, formed a sort of confederation, in which, however, the Thebans and the other Bœotians frequently came into hostile collision, Thebes claiming the supremacy of the whole country, and the other cities insisting on their independence. The confederation was administered by a number of officers called Bœotarchs, of whom two were chosen by Thebes and one by each of the remaining confederate communities. The federal temple was that of Athene Itonica at Coronea, and there a religious festival was held. The political history of the country is inseparable from that of ORCHOMENOS, THEBES, PLATÆÆ, and THESPIÆ, to which the reader must be referred for details. The confederacy continued its nominal existence even under the Roman emperors, although the country was so reduced that, about the time of Augustus, Tanagra and Thespiæ alone could be considered towns, the other cities having either been entirely destroyed, or existing only as villages. The more important of the towns which had formerly existed, besides those already mentioned, were Tegyra, Arne, Haliartus, Alalcomenæ, and Lebadea in the Copaic valley; Anthedon, Mycalessus, and Oropus along the Euripus; Thisbe and Creusis on the Corinthian Gulf; Ascra and Leuctra further inland; and Sidæ, Tanagra, and Pheræ in the valley of the Asopus. During the Middle Ages and under the Turkish domination, Livadia, the ancient Lebadea, was the capital of the country, which indeed was frequently called after that city. The district is now united in one *Nomos* with Attica (Attikoviotia), and is divided into two eparchies that take their names from Thebes and Livadia. The population in the eastern part is largely Albanian, and is engaged in the growing of grain and culture of the vine. See the Travels of Clarke, Wheler, Dodwell, Sir W. Gell, Hobhouse, Holland, Leake, and Mure; Thiersch, *État actuel de la Grèce*, 1833; Forchhammer, *Hellenika*, 1837; Kruse, *Hellas*, 1825–28; Klütz, *De fœdere Bœotico*, 1821; Ten Breujel, *De fœdere Bœotico*, 1834; Francke, *Der Böotische Bund*, 1843; and Bursian's *Geographie von Griechenland*, 1863.

BOERHAAVE, HERMANN, one of the most celebrated physicians of modern times, was born at Voorhout near Leyden, December 31, 1668. Destined for the clerical profession, to which his father belonged, he received a liberal education, and early displayed unusual abilities. At the age of sixteen he entered the University of Leyden, where he studied under Gronovius, Ryckius, Trigland, and other distinguished men, and obtained the highest academical honours. In 1690 he took his degree in philosophy; on which occasion he delivered an inaugural dissertation *De distinctione mentis a corpore*, wherein he attacked the doctrines of Epicurus, Hobbes, and Spinoza. Being left, on the death of his father, without any provision, he was compelled to support himself by teaching mathematics. By the advice of Vandenberg, the burgomaster of Leyden, Boerhaave now applied himself with ardour to the study of medicine, to which indeed he had early manifested a decided inclination. The works of Hippocrates among the ancients, and those of Sydenham among the moderns, were the especial objects of his study; but his reading was by no means confined to these authors. In 1693 he took his degree of M.D. at Harderwyck in Guelderland, and immediately entered on the studies of his profession. His merits were soon recognized, and in 1701 he was appointed by the University of Leyden to supply the place of Drelincourt as lecturer on the institutes of medicine. His inaugural discourse on this occasion was entitled *De commendando Hippocratis studio*, in which he recommended to his pupils that great physician as their model. In 1709, the university appointed him successor to Hotton in the chair of botany and medicine, in which capacity he did good service, not only to his own university, but also to botanical science, by his improvements and additions to the botanic garden of Leyden, and by the publication of numerous works descriptive of new species of plants. He was appointed in 1714 rector of the university. In the same year he succeeded Bidloo in the chair of practical medicine, and in this capacity he had the merit of introducing into modern practice the system of clinical instruction. Four years later he was appointed to the

chair of chemistry, and delivered an inaugural discourse, which contains the germs of his celebrated *Elements of Chemistry*. In 1728 he was elected into the Royal Academy of Sciences of Paris, and two years later into the Royal Society of London; to both of which he communicated his chemical researches. In 1729 declining health obliged him to resign the chairs of chemistry and botany; and in 1731 he resigned the rectorship of the university, to which office he had been re-elected. On this occasion he delivered a discourse *De Honore Medici Servitute*. This great and good man died, after a lingering and painful illness, on the morning of the 23d September 1738.

From the time of Hippocrates, no physician had more justly merited the esteem of his contemporaries and the admiration of posterity than Boerhaave. To uncommon intellectual abilities he united those amiable qualities of the heart which give them so great a value to society. His personal appearance was simple and venerable. He taught very methodically, and with great precision; his style was eloquent, and his delivery dignified and graceful. He sometimes also gave his lectures a lively turn; but his raillery was never coarse or satirical. He possessed remarkable powers of memory, and was an accomplished linguist. A declared foe to all excess, he considered decent mirth as the salt of life. He was fond of music, with which he had a scientific acquaintance; and during winter he had a weekly concert in his house. It was his daily practice throughout life, as soon as he rose in the morning, which was generally very early, to retire for an hour to private prayer and meditation on some part of the Scriptures. He often told his friends, when they asked him how it was possible for him to go through so much fatigue, that it was this practice which gave him spirit and vigour in the business of the day.

Of his sagacity, and the wonderful penetration with which he often discovered and described, at first sight, such distempers as betray themselves by no symptoms to common eyes, very surprising accounts have been transmitted to us. Yet so far was he from having presumptuous confidence in his own abilities, or from being puffed up by prosperity, that he was condescending to all, and remarkably diligent in his profession. His great skill and celebrity as a physician brought him a large fortune. He left his only surviving daughter two millions of florins.

The genius of Boerhaave raised the fame of the University of Leyden, especially as a school of medicine, so as to make it a resort of strangers from every part of Europe. All the princes of Europe sent him disciples, who found in this skilful professor not only an indefatigable teacher, but an affectionate guardian. When Peter the Great went to Holland in 1715, to instruct himself in maritime affairs, he also took lessons from Boerhaave. The reputation of this eminent man was not confined to Europe; a Chinese mandarin wrote him a letter directed "To the illustrious Boerhaave, physician in Europe," and it reached him in due course. The city of Leyden raised a splendid monument to his memory in the church of St Peter, inscribed "To the health-giving genius of Boerhaave," SALUTIFERO BOERHAAVII GENIO SACRUM.

The principal works of Boerhaave are—(1.) *Institutiones Medicæ*, Leyden, 1708; (2.) *Aphorismi de cognoscendis et curandis Morbis*, Leyden, 1709,—on this work, which was the text-book of Boerhaave's lectures, Van Swieten published a commentary in 5 vols. 4to; (3.) *Libellus de Materia Medica et Remediorum Formulis*, Leyden, 1719; (4.) *Institutiones et Experimenta Chemiæ*, Paris, 1724.

BOETIUS, ANICIUS MANLIUS SEVERINUS, is described by Gibbon "as the last of the Romans whom Cato or Tully could have acknowledged for their countryman." The events of his life are involved in uncertainty. The historians of the day give us but imperfect records or make unsatisfactory allusions. Later chroniclers indulged in the fictitious and the marvellous, and it is almost exclusively from his own books that trustworthy information can be obtained.

There is considerable diversity among authorities as to the name of Boetius. One editor of his *De Consolatione*, Bertius, thinks that he bore the prænomen of Flavius, but there is no authority for this supposition. His father bore the name of Flavius, and it is probable that the Flavius Boetius who was prætorian prefect, and who was put to death in 455 A.D., by order of Valentinian III., was the grandfather of the subject of our notice; but these circumstances form no good reason for supposing that he also had the prænomen of Flavius. Many of the earlier editions inserted the name of Torquatus, but it is not found in any of the best manuscripts. The last name is generally written Boethius, from the idea that it is connected with the Greek βοηθός; but here, again, the best manuscripts agree in reading Boetius, and the latest editors have adopted this form.

The date of his birth is unknown; but it is conjectured on good grounds that he was born at Rome somewhere about the year 475 A.D. He was, therefore, too young to see the last of the Roman emperors (476), and his boyhood was spent in Rome while Odoacer, king of the Heruli, was monarch of that city. We know nothing of his early years. A passage in a treatise falsely ascribed to him (*De Disciplina Scholarium*) and a misinterpretation of a passage in Cassiodorus, led early scholars to suppose that he spent a long time in Athens pursuing his studies there; but later biographers have seen that there is no foundation for this opinion. His father, Flavius Manlius Boetius, was consul in the year 487. It is probable that he died soon after; for Boetius states that, when he was bereaved of his parent, men of the highest rank took him under their charge (*De Con.*, lib. ii. c. 3). He soon became well known for his energy and ability, and his high rank gave him access to the noblest families. He married Rusticiana, the daughter of the senator Symmachus. By her he had two sons, Anicius Manlius Severinus Boetius and Q. Aurelius Memmius Symmachus. When Theodoric, the king of the Ostrogoths, displaced Odoacer no change of fortune for the worse seems to have befallen Boetius. On the contrary he became a favourite with that monarch, and was one of his intimate friends. Boetius attained to the consulship in 510, and his sons, while still young, held the same honour together (522). Boetius regarded it as the height of his good fortune when he witnessed his two sons, consuls at the same time, conveyed from their home to the senate-house by a crowd of senators amidst the enthusiasm of the masses. On that day, he tells us, while his sons occupied the curule chairs in the senate-house, he himself had the honour of pronouncing a panegyric on the monarch, and placed between his two sons he distributed largesses among the people in the circus. But his good fortune did not last, and he attributes the calamities that came upon him to the ill-will which his bold maintenance of justice had caused, and to his opposition to every oppressive measure. "How often," he says, "have I opposed the attacks of Conigastus on the property of the weak? how often have I kept Trigguilla, the chamberlain of the palace, from perpetrating acts of injustice? how often have I protected, by influence exercised at my own peril, the miserable whom the licensed avarice of the barbarians always harassed with endless insults?" And then he mentions several particular cases. A famine had begun to rage. The prefect of the praetorium was determined to satisfy the soldiers, regardless altogether of the feelings of the provincials. He accordingly issued an edict for a *coemptio*, that is, an order compelling the provincials

to sell their corn to the Government, whether they would or not. This edict would have utterly ruined Campania. Boetius interfered. The case was brought before the king, and Boetius succeeded in averting the *coemptio* from the Campanians. He also rescued Paulinus, a man of consular rank, from the jaws of those whom he calls *palatinæ canes* (dogs of the palace), and who, he says, had almost devoured his riches. And he gives as a third and crowning instance in that he exposed himself to the hatred of the informer Cyprianus by preventing the punishment of Albinus, a man of consular rank. He mentions in another place that when at Verona the king was anxious to transfer the accusation of treason brought against Albinus to the whole senate, he defended the senate at great risk. In consequence of the ill-will that Boetius had thus roused, he was accused of treason towards the end of the reign of Theodoric. Three accusers appeared against him. The first, Basilius, had been expelled from the monarch's service, and in consequence of debt he had become an informer and now appeared against Boetius. The other two were Opilio and Gaudentius, on whom sentence of banishment had been pronounced on account of innumerable frauds. They first took refuge in a church, but when this fact became known, a decree was issued that if they did not leave Ravenna before a prescribed day, they were to be driven out with a brand upon their forehead. On the very last day allowed them they gave information against Boetius, and their information was received. The accusation which these villains brought against him was that he had conspired against the king, that he was anxious to maintain the integrity of the senate, and to restore Rome to liberty, and that for this purpose he had written to the Emperor Justin. Justin had, no doubt, special reasons for wishing to see an end to the reign of Theodoric. Justin was orthodox. Theodoric was an Arian. The orthodox subjects of Theodoric were suspicious of their ruler; and many would gladly have joined in a plot to displace him. The knowledge of this fact may have rendered Theodoric suspicious. But Boetius denied the accusation in unequivocal terms. He did indeed wish the integrity of the senate. He would fain have desired liberty, but all hope of it was gone. The letters addressed by him to Justin were forgeries, and he had not been guilty of any conspiracy. Notwithstanding his innocence he was condemned and sent to Ticinum (Pavia) where he was thrown into prison. It was during his confinement in this prison that he wrote his famous work *De Consolatione Philosophiæ*. His goods were confiscated, and after an imprisonment of considerable duration he was put to death in 525. Procopius relates that Theodoric soon repented of his cruel deed, and that his death, which took place soon after, was hastened by remorse for the crime he had committed against his great counsellor.

Two or three centuries after the death of Boetius writers began to view his death as a martyrdom. Several Christian books were in circulation which were ascribed to him, and there was one especially on the Trinity which they regarded as proof that he had taken an active part against the heresy of Theodoric. It was therefore for his orthodoxy that Boetius was put to death. And these writers delight to paint with minuteness the horrible tortures to which he was exposed and the marvellous actions which the saint performed at his death. He was canonized as Saint Severinus. The brick tower in Pavia in which he was confined was a hallowed building. And finally, in the year 996, Otho III. ordered the bones of Boetius to be taken out of the place in which they had lain hid, and to be placed in the church of St Augustine within a splendid marble tomb, for which Gerbert, who afterwards became Pope under the name of Silvester II., wrote an inscription. It should be mentioned also that some have given him a decidedly Christian wife, of the name of Elpis, who wrote hymns, two of which are still extant (Daniel, *Thes. Hymn.*, i. p. 156). This is a pure supposition inconsistent with chronology, unauthenticated by authority, and based only on a misinterpretation of a passage in the *De Consolatione*.

The contemporaries of Boetius regarded him as a man of profound learning. Priscian the grammarian speaks of him as having attained the summit of honesty and of all sciences. Cassiodorus, the chancellor of Theodoric and the intimate acquaintance of the philosopher, employs language equally strong. And Ennodius, the bishop of Pavia, knows no bounds for his admiration. "You surpass," he says to Boetius, "the eloquence of the ancients in imitating it." The king Theodoric had a profound idea of his great scientific abilities. He employed him in setting right the coinage. When he visited Rome with Gunibald king of the Burgundians, he took him to Boetius, who showed them, amongst other mechanical contrivances, a sun-dial and a water-clock. The foreign monarch was astonished, and, at the request of Theodoric, Boetius had to prepare others of a similar nature, which were sent as presents to Gunibald. It was Boetius also whom Theodoric consulted when Clovis, king of the Franks, wished a musician who could sing to the accompaniment of the lyre, and Boetius was charged with the duty of selecting him.

The fame of Boetius increased after his death, and his influence during the Middle Ages was exceedingly powerful. His circumstances peculiarly favoured this influence. He appeared at a time when contempt for intellectual pursuits had begun to pervade society. In his early years he was seized with a passionate enthusiasm for Greek literature, and this continued through life. Even amidst the cares of the consulship he found time for commenting on the *Categories* of Aristotle. The idea laid hold of him of reviving the spirit of his countrymen by imbuing them with the thoughts of the great Greek writers. He formed the resolution to translate all the works of Aristotle and all the dialogues of Plato, and to reconcile the philosophy of Plato with that of the Stagirite. He did not succeed in all that he designed; but he did a great part of his work. "Through your translations," says Cassiodorus to him, "the music of Pythagoras and the astronomy of Ptolemæus are read by the Italians; the arithmetic of Nicomachus and the geometry of Euclid are heard by the Westerns; the theology of Plato and the logic of Aristotle dispute in the language of Quirinus; the mechanical Archimedes also you have restored in a Latin dress to the Sicilians; and whatever discipline or arts fertile Greece has produced through the efforts of individual men, Rome has received in her own language through your single instrumentality." Boetius translated into Latin Aristotle's *Analytica Priora et Posteriora*, the *Topica*, and *Elenchi Sophistici*; and he wrote commentaries on Aristotle's *Categories*, on his book περὶ ἑρμηνείας, also a commentary on the *Isagoge* of Porphyrius. These works formed to a large extent the source from which the Middle Ages derived their knowledge of Aristotle. (See Stahr, *Aristoteles bei den Römern*, pp. 196–234.)

But Boetius did not confine himself to Aristotle. He wrote a commentary on the *Topica* of Cicero; and he was also the author of independent works on logic:—*Introductio ad Categoricos Syllogismos*, in one book; *De Syllogismo Categorico*, in two books; *De Syllogismis Hypotheticis*, in two books; *De Divisione*, in one book; *De Definitione*, in one book; *De Differentiis Topicis*, in four books.

We have also seen from the statement of Cassiodorus that he furnished manuals for the quadrivium of the schools of the Middle Ages (the "*quattuor matheseos disciplinæ*,"

as Boetius calls them) on arithmetic, music, geometry, and astronomy. The statement of Cassiodorus that he translated Nicomachus is rhetorical. Boetius himself tells us in his preface addressed to his father-in-law Symmachus that he had taken liberties with the text of Nicomachus, that he had abridged the work when necessary, and that he had introduced formulæ and diagrams of his own where he thought them useful for bringing out the meaning. His work on music also is not a translation from Pythagoras, who left no writing behind him. But Boetius belonged to the school of musical writers who based their science on the method of Pythagoras. They thought that it was not sufficient to trust to the ear alone, to determine the principles of music, as did practical musicians like Aristoxenus, but that along with the ear, physical experiments should be employed. The work of Boetius is in five books, and is a very complete exposition of the subject. It remained a text-book of music in the Universities of Oxford and Cambridge till within comparatively recent times. It is still very valuable as a help in ascertaining the principles of ancient music, and gives us the opinions of some of the best ancient writers on the art. The manuscripts of the geometry of Boetius differ widely from each other. The latest editor, Godofredus Friedlein, thinks that there are only two manuscripts which can at all lay claim to contain the work of Boetius. He has published the *Ars Geometriæ*, in two books, as given in these manuscripts; but critics are generally inclined to doubt the genuineness even of these.

By far the most important and most famous of the works of Boetius is his book *De Consolatione Philosophiæ*. Gibbon justly describes it as "a golden volume, not unworthy of the leisure of Plato or Tully, but which claims incomparable merit from the barbarism of the times and the situation of the author." It was a favourite book of the Middle Ages, and deserves to be a favourite still. The high reputation it had in mediæval times is attested by the numerous translations, commentaries, and imitations of it which then appeared. Among others Asser, the instructor of Alfred the Great, and Robert Grosseteste, bishop of Lincoln, commented on it. Alfred translated it into Anglo-Saxon. Versions of it appeared in German, French, Italian, Spanish, and Greek before the end of the 15th century. Chaucer translated it into English prose before the year 1382; and this translation was published by Caxton at Westminster, 1480. Lydgate followed in the wake of Chaucer. It is said that, after the invention of printing, amongst others Queen Elizabeth translated it, and that the work was well known to Shakespeare.

This famous work consists of five books. Its form is peculiar, and is an imitation of a similar work by Marcianus Capella, *De Nuptiis Philologiæ et Mercurii*. It is alternately in prose and verse. The verse shows great facility of metrical composition, but a considerable portion of it is transferred from the tragedies of Seneca. The first book opens with a few verses, in which Boetius describes how his sorrows had turned his hair grey, and had brought him to a premature old age. As he is thus lamenting, a woman appears to him of dignified mien, whom for a time he cannot distinguish in consequence of his tears, but at last he recognizes her as his guardian, Philosophy. She, resolving to apply the remedy for his grief, puts some questions to him for that purpose. She finds that he believes that God rules the world, but does not know what he himself is; and this absence of self-knowledge is the cause of his weakness. In the second book Philosophy presents to Boetius Fortune, who is made to state to him the blessings he has enjoyed, and after that proceeds to discuss with him the kind of blessings that fortune can bestow, which are shown to be unsatisfactory and uncertain. In the third book Philosophy promises to lead him to true happiness, which is to be found in God alone, for since God is the highest good, and the highest good is true happiness, God is true happiness. Nor can real evil exist, for since God is all-powerful, and since he does not wish evil, evil must be non-existent. In the fourth book Boetius raises the question, Why, if the governor of the universe is good, do evils exist, and why is virtue often punished and vice rewarded? Philosophy proceeds to show that this takes place only in appearance; that vice is never unpunished nor virtue unrewarded. From this Philosophy passes into a discussion in regard to the nature of providence and fate, and shows that every fortune is good. The fifth and last book takes up the question of man's free will and God's foreknowledge, and, by an exposition of the nature of God, attempts to show that these doctrines are not subversive of each other; and the conclusion is drawn that God remains a foreknowing spectator of all events, and the ever-present eternity of his vision agrees with the future quality of our actions, dispensing rewards to the good and punishments to the wicked.

Several theological works have been ascribed to Boetius, as has been already mentioned. The *Consolatio* affords conclusive proof that the author was not a practical believer in Christianity. The book contains several expressions, such as *daemones*, *angelica virtus*, and *purgatoria clementia*, which have been thought to be derived from the Christian faith; but they are used in a heathen sense, and are explained sufficiently by the circumstance that Boetius was on intimate terms with Christians, and could not help being influenced to some extent by their language. The writer nowhere finds consolation in any Christian belief, and Christ is never named in the work. It is not impossible, however, that Boetius may have been brought up a Christian, and that in his early years he may have written some Christian books. This is the conjecture to which the latest editor of his Christian treatises has had recourse. Peiper thinks that the first three treatises are the productions of the early years of Boetius. The first, *De Sancta Trinitate*, is addressed to Symmachus (Domino Patri Symmacho), and the result of the short discussion, which is of an abstract nature, and deals partly with the ten categories, is that unity is predicated absolutely, or, in regard to the substance of the Deity, trinity is predicated relatively. The second treatise is addressed to John the deacon ("Ad Joannem Diaconum"), and its subject is "Utrum Pater et Filius et Spiritus Sanctus de divinitate substantialiter prædicentur." The treatise is shorter than the former, occupying only two or three pages, and the conclusion of the argument is the same. The third treatise bears the title, *Quomodo substantiæ in eo quod sint bonæ sint cum non sint substantialia bona*. It contains nothing distinctly Christian, and it contains nothing of great value; therefore its authorship is a matter of little consequence. Peiper thinks that, as the best MSS. uniformly assign these treatises to Boetius, they are to be regarded as his; that it is probable that Symmachus and John (who afterwards became Pope) were the men of highest distinction who took charge of him when he lost his father; and that these treatises are the first-fruits of his studies, which he dedicates to his guardians and benefactors. He thinks that the variations in the inscriptions of the fifth treatise, which is not found in the best manuscript, are so great that the name of Boetius could not have originally been in the title. The fourth book is also not found in the best manuscript, and two manuscripts have no inscription. He infers, from these facts, that there is no sure evidence for the authorship of the fourth and fifth treatises. The fifth treatise is *Contra Eutychen et Nestorium*. Both Eutyches and Nestorius are spoken of as living. A council is mentioned, in which a letter was read, expounding the opinion of the Eutychians for the first time. The novelty of the opinion is also alluded to. All these circumstances point to the Council of Chalcedon (451). The treatise was therefore written before the birth of Boetius, if it be not a forgery; but there is no reason to suppose that the treatise was not a genuine production of the time to which it professes to belong. The fourth treatise, *De Fide Catholica*, does not contain any distinct chronological data; but the tone and opinions of the treatise produce the impression that it probably belonged to the same period as the treatise against Eutyches and Nestorius. Several inscriptions ascribe both these treatises to Boetius. It will be seen from this statement that Peiper bases his conclusions on grounds far too narrow; and on the whole it is far more probable that Boetius wrote none of the four Christian treatises, particularly as they are not ascribed to him by any of his contemporaries. Three of them express in the strongest language the orthodox faith of the church in opposition to the Arian heresy, and these three put in unmistakable language the procession of the Holy Spirit from both Father and Son. The fourth argues for the orthodox belief of the two natures and one person of Christ. When the desire arose that it should be believed that Boetius perished from his opposition to the heresy of Theodoric, it was natural to ascribe to him works which were in harmony with this supposed fact. The works may really have been written by one Boethus, a bishop of Africa, as Jourdain supposes, or by some Saint Severinus, as Nitzsch conjectures, and the similarity of name may have aided the transference of them to the heathen or neutral Boetius.

The best editions of the entire works of Boetius are the Basel edition of 1570, and Migne's in his *Patrologiæ Cursus Completus, Series Latina*, vols. lxiii., lxiv. There are many editions of the *De Consolatione*. The most recent are—(1.) In Valpy's *Delphin Classics*, Nos. 54 and 55. This contains the lives of Boetius by Bertius and

by Rota, and a list of the various editions of Boetius. It has also numerous notes. (2.) An edition by Theodorus Obbarius, Jenæ, 1843. This contains prolegomena on the life and writings of Boetius, on his religion and philosophy, and on the manuscripts and editions, a critical apparatus, and notes. (3.) An edition by Rudolfus Peiper, Lipsiæ, 1871. This edition has the fullest collation of manuscripts, though a considerable number of manuscripts still remain to be collated. In addition to an account of the MSS. used, it gives the Book of Lupus "De Metris Boetii," the "Vita Boetii" contained in some MSS., "Elogia Boetii," and a short list of the commentators, translators, and imitators of the *Consolation*. It contains also an account of the metres used by Boetius in the *Consolatio*, and a list of the passages which he has borrowed from the tragedies of Seneca. The work also includes the five treatises, four of them Christian, of which mention has been made above. In 1867 appeared a very satisfactory edition of Boetius's works, *De Institutione Arithmetica Libri Duo, De Institutione Musica Libri Quinque, Accedit Geometria quæ fertur Boetii*: e libris manu scriptis edidit Godofredus Friedlein, Lipsiæ. (J. D.)

BOGHAZ-KEUY, or BOGHAS-KOEI (*i.e.*, the Village of the Gorge), a small hamlet in Asia Minor, remarkable for its ruins, which are identified with the ancient Pterium or Pteria. It stands 3515 feet above the sea-level, about half-way between Angora and Amassia, almost in the 40th parallel of N. lat., on the banks of a small tributary of the Kizil Irmak. The present village contains about 150 houses, but the remains give evidence of its former importance. Almost all the heights they occupy bear traces of fortification; extensive chambers have been excavated in the rocks; many portions of escarpment are elaborately sculptured; and the massive foundations of a vast temple or palace can still be traced. The date and origin of these ruins have given rise to much discussion. Dr Barth thinks the city was probably founded by Cyaxares, the Mede, and explains the groups of sculpture as commemorating the peace between Cyaxares and Alyattes, which is described by Herodotus in the 74th chapter of his 1st book. M. Texier's hypothesis, on the other hand, is that the carvings represent the introduction of the worship of Astarte into Phrygia; and this interpretation has been provisionally accepted by Van Lennep, in whose *Travels in Asia Minor*, 1870, carefully-drawn copies of the sculptures will be found. (See also Barth, *Reise von Trapezunt nach Scutari*, 1860, and in *Monatsbericht der Berl. Akad. der Wissensch.*, Febr., 1859.)

BOGODUKHOFF, a town of Russia, in the government of Kharkoff, about 43 miles N.W. of that city, in 50° 10′ N. lat. and 36° 32′ E. long., on the sandstone heights along the River Merl. There seems to have been a settlement on this site as early as 1571, and in 1681 it is spoken of as a town. In 1709, at the time of the Swedish war, Bogodukhoff was taken by Menschikoff and the Emperor Alexis Petrovitch. There are still remains of the ramparts and ditches with which it was formerly surrounded. The town contains four churches and a cathedral (of the Assumption, built in 1793), a hospital, and an almshouse. The inhabitants are chiefly engaged in agriculture and gardening, and in the manufacture of boots, caps, and furred gowns. Tanning also is carried on to some extent. The trade is principally in grain, cattle, and fish. There are two weekly markets and six annual fairs. Population in 1860, 10,522.

BOGOMILI, a heretical sect of the Greek Church, who came into notice during the 12th century. In origin they are probably Bulgarian, and their name appears to be a compound of the Slavonic words *Bog*, God, and *milui*, have mercy. In doctrine they are closely assimilated to the Euchites of the preceding century, and they may be looked on as an offshoot of that older sect. The peculiarity of their system of belief is the place assigned to Satan, who, under his original name Satanael, is held by them to be the first-born son of God. But Satanael, though seated at the right hand of his father and endowed with universal sway, was discontented and desired to become independent. He led away a section of the angels from their allegiance, and with their aid formed out of chaos a new world—the earth, and a new race—man. But he was unable to give to man a portion of his own living spirit, and therefore besought God to bestow life on this new creation, promising that the vacant places of the seceded angels should be filled up by the spirits of men. Repenting of this promise, however, he resolved to bring forth an evil race which should overwhelm the good among mankind. He accordingly seduced Eve, who gave birth to Cain, the first of the descendants of the evil principle. His power also enabled him to deceive the greater part of mankind, particularly the Jews, to whom he represented himself as Jehovah. At last God sent out from himself the *Logos*, or angel Michael, who came upon earth in an ethereal form which was in appearance only an earthly body. Christ overcame Satanael, and deprived him of his creative power, *El*, from which time he is called Satan. Christ then ascended and took his place beside the Father, who again sent forth an emanation, the Holy Ghost, for the comfort and edification of believers. In church observances the Bogomili were equally heterodox. They rejected baptism by water only, and made the ceremony consist of prayer, and of laying on the head of the convert the gospel (probably apocryphal) of St John, and the hands of the congregation. As they rejected the symbol of water in baptism so they refused to admit such symbolic rites as the Lord's supper, which they looked upon as an offering to evil spirits. They were averse to all images, even to the cross. The Bogomili suffered persecution from Alexius Comnenus, who put to death their leader Basilius, and they were condemned by a synod of Constantinople in 1140. They lingered on, however, in and about Philippopolis, and opinions nearly identical with theirs are to be met with among the later Catharists. (See the *Church Histories* of Neander and Gieseler.)

BOGOTA, or SANTA FÉ DE BOGOTA, the capital of the United States of Colombia, in South America, is situated in the state of Cundinamarca, in 4° 6′ N. lat. and 78° 30′ W. long. It occupies a fine position at the base of the mountains of Guadalupe and Montserrato, on a table-land that forms part of the eastern ridge of the Andes, between the extensive valley of the Magdalena and the plains that are watered by part of the Orinoco system. The surrounding country is exceedingly fertile, and produces abundant crops of wheat and barley and the leguminous plants cultivated in Europe. The city of Bogota is the finest in the republic; its streets are well built, and run at right angles to each other; and within recent years most of them have been supplied with side pavements. The private houses are built of sun-dried bricks, and whitewashed; and owing to the prevalence of earthquakes they are mostly of one story in height. Of the streets the largest and finest is the Calle-Real or Calle de la Republica, which ends in a large square or plaza containing some of the chief buildings in the city. The cathedral, rebuilt in 1814, possesses very little external beauty; but its interior is fitted up with considerable elegance, its ornaments are rich and valuable, and the image of the Virgin, the patron saint, is covered with a profusion of precious stones. There are about thirty other churches in the city, but many of them are in a state of decay, while several of the monastic buildings are appropriated to secular uses,—the religious communities having been dissolved by Mosquera, and their revenues devoted in great measure to educational purposes. The convent of San Francisco is of great extent, and contains some of the productions of Vasquez, a native artist of merit. A large and elegant building—a capitol, for the reception of Congress and for the various offices of state—is now (1875) in course of erection. Besides the university there are three endowed colleges, a school of

chemistry and mineralogy, a national academy, a public library, a botanic garden, and a military school, which is supported out of the public funds, and has produced some good engineers. The mint, one of the three in the republic, is a large and handsome building, and is well supplied with the necessary machinery. There are manufactures of soap, cloth, leather, and the precious metals; an active trade is carried on, and the neighbourhood is rich in minerals of various kinds. The population in 1800 amounted to 21,464, exclusive of strangers and temporary residents; in 1821 it was estimated at 30,000, and in 1870 at about 52,000. Santa Fé de Bogota was founded in 1538 by Gonzalez Ximenes de Quesada, and received its name from his birthplace Santa Fé, with the addition of Bogota, in honour, it is said, of a native prince of that time. It soon increased in size and importance, and became the capital of the Spanish vice-royalty of New Granada. In 1811 the citizens threw off the Spanish yoke and a republic was proclaimed; the city, however, in 1816, fell into the hands of Murillo the Spanish general. Delivered by Bolivar in 1819 it was made capital of the republic of Colombia; on the separation of the three states it remained the chief city of New Granada, and it is now the capital of the United States of Colombia, forming itself an independent federal territory. It is the seat of the supreme court and the other offices of the Federal Government, and the residence of the foreign diplomatic representatives.

BOGRA, correctly BAGURÁ, a district in the Rájsháhí division, within the Lieutenant-Governorship of Bengal, situated between 25° 20′ and 24° 20′ 28″ N. lat., and 88° 55′ 30″ and 89° 49′ 25″ E. long. It is bounded on the N. by the districts of Dinájpur and Rangpur, on the E. by the districts of Rangpur and Maimansinh, on the S. by the district of Pabná, and on the W. by the districts of Rájsháhí and Dinájpur. The revenue area of the district in 1870 was 2000 square miles, of which 1750 were returned as under cultivation, 125 as cultivable but not actually cultivated, and 125 as uncultivable waste. The census of 1872 returned the police area of the district at 1500 square miles, and disclosed a population of 689,467 souls, of whom 556,620, or 80 per cent., were Mahometans; 130,644, or 19 per cent., Hindus; 22 Christians; and 2181 were classified as "others." Density of population in the census area, 59 per square mile. The district stretches out in a level plain, intersected by numerous streams and dotted with patches of jungle. The Karatoyá River flows from north to south, dividing the district into two portions, possessing very distinct characteristics. The eastern tract consists of rich alluvial soil, well-watered, and subject to fertilizing inundations, yielding heavy crops of coarse rice, oilseeds, and jute. The western portion of the district is high-lying and produces the finer qualities of rice. The principal rivers are formed by the different channels of the Brahmaputra, which river here bears the local names of the Konái, the Dáokobá, and the Jamuná, the last forming a portion of the eastern boundary of the district. Its bed is studded with alluvial islands. The Brahmaputra and its channels, together with three minor streams, the Bangálí, Karatoyá, and Alai, afford admirable facilities for commerce, and render every part of the district accessible to native cargo boats of large burden. The rivers swarm with fish,—the value of the fisheries being estimated at £45,000 a year. The principal products of the district are rice, pease, pulses, oilseeds, jute, sugar-cane, mulberry, red pepper, and hemp for smoking (*Cannabis indica*). These products, together with clarified butter and a little silk, form the chief articles of export. The imports consist of salt, cloth, tobacco, areca-nuts, copper and brass utensils, spices, iron and piece goods. The chief trading markets are Bográ, Lakhmíganj, Buríganj, Dhupcháchiá, &c. A silk factory has been established at Naodápárá, and is conducted with European capital, with an annual outlay of about £4500. The revenue and expenditure of the district have steadily increased of late years. In 1853 the total revenue of the district amounted to £48,431, and the civil expenditure to £7282; in 1860, revenue £57,744, and civil expenditure £11,013; in 1870–71 the revenue had risen to £59,979. In 1870–71 the district contained 1064 separate estates held by 2497 proprietors, paying a total Government land revenue of £44,347. The machinery for protecting person and property consists of six magisterial and six civil courts, with (1) a regular police force, numbering 54 officers and 252 men, and costing Government £5975; (2), a rural constabulary or village watch, numbering 2552 men, and costing £6635, paid by the landholders and villagers; and (3), municipal police, numbering 36 men, and costing £251. In 1871–72 there were 41 Government and aided schools in the district, attended by 1492 pupils, and maintained at a total cost of £1398, of which £692 was contributed by the state. The total number of aided and unaided schools in the district is returned in the census of 1872 at 169, attended by 1685 pupils. The only town containing upwards of 5000 inhabitants in the district is Bográ, the administrative headquarters, situated on the Karatoyá River; population in 1872, 5872; municipal income, £282; expenditure, £208; rate of taxation per head, 11½d. There is one other municipality, Sherpur, formerly a place of importance when the East India Company had silk filatures in its neighbourhood. A great part of this town is now overgrown with jungle; the municipal income in 1869 was £246, the expenditure £174. The climate of Bogra is mild during the winter, but sultry and oppressive at other seasons. The average annual rainfall for the five years ending 1869 was 82 inches, and the average annual temperature 77° Fahr.

BOHADDIN, or, more properly, BOHA-EDDYN, an eminent Arabian writer and statesman, better known in the East under the appellation of IBN-SJEDDAD. He was born at Mosul 1145 A.D. (539 A.H.), and early became eminent in the study of the Koran, as well as in jurisprudence. At the age of twenty-seven he obtained the place of lecturer at Baghdad, and, soon after, a professor's chair at Mosul. In 1187 he made the pilgrimage to Mecca, and then proceeded to visit Jerusalem and Hebron. In passing through Damascus he was sent for by Saladin, who was then employed in the siege of Kancab. Bohaddin observed, as he himself mentions (*Vita Saladini*, c. v.), that the whole soul of the monarch was engrossed by the war which he was then waging against the enemies of the faith, and saw that the only mode of acquiring his favour was by urging him to its vigorous prosecution. With this view he composed a treatise on the *Laws and Discipline of Sacred War*; and this work, on his return, he presented to Saladin, who received it with peculiar favour. Bohaddin, from this time, remained constantly attached to the person of the sultan, and was employed on various important embassies and departments of civil government. He was also appointed judge of the army, and judge of Jerusalem. After Saladin's death, Bohaddin was active in securing the throne to his son, Melik-al-Dhaker, and was by that prince created cadi of Aleppo. He then founded a college in that city of which he himself was the principal professor. When Melik-al-Dhaker died, his son Melik-al-Aziz was a minor, and Bohaddin obtained the principal sway in the regency. This gave him an opportunity of introducing learned men at court, and loading them with honours. As the prince, however, approached to manhood, Bohaddin, though he still retained his offices, found it expedient to retire from court. Even after he was unable to go to college, he continued to

give lectures in his own house; and he persevered in these learned labours till the age of ninety, when he died 1235 A.D. (633 A.H.) Bohaddin wrote on jurisprudence and Muslim divinity; but his principal work is his *Life of Saladin*, which, with several other pieces connected with the same subject, was published by Schultens, at Leyden, in 1732, accompanied by a Latin translation, with notes and a geographical index. This work affords a favourable specimen of the historical compositions of the Arabs. It is written with some spirit, and yet is free from that inflation which so frequently disfigures Oriental composition. Whatever relates to Saladin breathes the highest tone of panegyric; yet the enthusiasm with which everything concerning him is narrated, and the anecdotes which the author, from his personal knowledge, is able to communicate respecting that extraordinary character, give his work a great degree of interest.

BOHEMIA (German BÖHMEN or BOHEIM), a kingdom of the Austrian empire, situated between 48° 33′ and 51° 4′ N. lat., and 12° 5′ and 16° 25′ W. long., and bounded on the N. by Saxony and Prussian Silesia, E. by Moravia, S. by Upper and Lower Austria, and W. by Bavaria. Its area is estimated at 19,983 square miles. It belongs almost entirely to the basin of the Elbe, which rises within the territory, and is joined by the Adler, the Iser, the Moldau, and the Eger before it passes the frontier. The boundaries are pretty clearly marked by mountain ranges on all sides,—the Bohmerwald dividing the country from Bavaria, the Erzgebirge and Riesengebirge from Saxony and Silesia, and the Moravian Hills from the basin of the Danube. The climate is healthy, but varies considerably in different districts; the soil in many parts is highly fertile, and grain of various kinds, potatoes, hops, flax, hemp, vines, and fruits are extensively cultivated. In 1870 there were 6,205,161 acres of ploughed land, 2656 in vineyards, 1,560,321 in gardens and meadows, 995,340 in pasture, and 3,749,411 in woodland. At the same date the number of horses in the country was 189,337, cattle 1,602,015, sheep 1,106,290, goats 194,273, swine 228,180, and bee-hives 140,892. The mineral productions comprise gold, silver, lead, tin, copper, iron, cobalt, bismuth, arsenic, sulphur, coal, alum, vitriol, and different sorts of stone. In 1870 there were obtained 156 cwt. of gold-ore, 1245 of silver-ore, 225,536 tons of iron, 999 tons of lead, 2274 of tin, 61 tons of antimony, and 111 of arsenic-ore. The quantity of coal and lignite amounted to 4,099,909 tons. The mineral springs of Bohemia—Carlsbad, Teplitz, Marienbad, and Franzensbrunn, &c.—are justly famous. The industry of the kingdom is highly developed in various directions. Most important of all is the manufacture of woollen goods, principally carried on at Reichenberg and in the neighbourhood. The cotton manufacture is also extensively prosecuted in the same district; and at Rumburg and other places linen stuffs are largely produced. Bohemian glass has been celebrated for centuries, and is still exported to all parts of Europe. Porcelain and earthenware of different sorts, iron and steel wares, copper, tin, and pewter articles, wooden wares, chemical stuffs, and paper are all the objects of a considerable industry. Beetroot sugar is pretty largely manufactured, the refineries numbering 126 in 1870. At the same date there were 968 breweries in the country, and 324 brandy distilleries. The chief commercial city is the capital, Prague; but Reichenberg, Pilsen, Haida, Rumburg, Leitmeritz, and Budweis are all important centres. Bohemia is divided into twelve circles—Prague, Budweis, Pisek, Pilsen, Eger, Saaz, Leitmeritz, Bunzlau, Jiczin, Königgrätz, Chrudim, Czaslau, and Tabor, and these are subdivided into 91 departments. In 1869 there were 372 towns, 226 smaller market-towns, and 12,551 villages. The number of inhabited houses in the whole country amounted to 632,404; and the total population was 5,106,069, of whom 2,433,629 were males, and 2,672,440 females. The census of 1869 took no count of nationality, but according to Ficker in his *Die Völkerstämme der Oesterreichisch-Ungarischen Monarchie*, there are 20 of German race for 32 of Slavonic. By far the greater part of the population (4,940,898) belongs to the Roman Catholic Church; while only 3438 are members of the Greek Church, 106,115 Protestants, and 89,933 Jews. The country constitutes an archbishopric, and is divided into three bishoprics. In 1870 there were 140 ecclesiastical foundations, with endowments amounting to £65,726. At the head of the educational establishments is the University of Prague, with four faculties, and attended in 1871 by 1516 students. There are upwards of 4000 ordinary schools in rather more than the half of which Czech is spoken, 26 gymnasiums, 4 theological seminaries, and several institutions for special departments of the arts and sciences.

Bohemia derives its name from the Boii, a Celtic race expelled from the country by the Marcomanni, who, after establishing a considerable kingdom under Marbod and being converted to Christianity, were in their turn supplanted by the Slavonic race, which is still predominant. The new comers were in danger of expulsion or conquest by the Avars, but were defended and established, according to their own possibly mythical account, by the heroic Samo; and somewhat later, as the story goes, his place was filled by the good knight Krok, whose daughter Libussa, marrying Premysl, became the founder of a regular dynasty. Bohemia was for a time absorbed in the great Carlovingian monarchy, but soon reasserted its independence. In the course of the 9th century Christianity was introduced. Under Boleslas I. the bounds of Bohemia were extended and its unity secured; but after a vigorous defence he had to recognize the overlordship of Otto I. of Germany. Under his grandchildren his kingdom fell to pieces; a Polish conquest followed, and the restoration of the native dynasty was only effected by the help of Henry II. of Germany. In 1086 Wratislas II. received the title of king from the emperor for himself; and Premysl Ottocar I. (1197–1230) became the founder of a hereditary series of kings. He was a bold defender of his independence, and at the same time gave great encouragement to German immigration. By the introduction of the right of primogeniture in the succession to the throne, he put an end to the disputes and contests which so often followed the death of a king. In 1241 his son and successor was the successful defender of Europe against a Mongolian invasion; but he was eclipsed by Ottocar II. (1253–1278), who added greatly by conquest to the extent of his dominions, and made himself a formidable rival to the emperor himself. The Premysl dynasty was at last extinguished in 1306; and after a few years of uncertainty and dissatisfaction the Bohemian crown was bestowed on John of Luxembourg (son of the Emperor Henry VII.), who thus became the founder of a dynasty which lasted till 1437. This warlike and prosperous monarch was succeeded by his son Charles I., who obtained the imperial dignity as Charles IV., and left Bohemia in a flourishing and influential position at his death in 1378. Under his successors, who fell far below the character of their ancestor, the country was thrown into confusion by the Hussite reformation, which resulted in a protracted war (1419–1434). The success of the reforming party led to an elective monarchy, and after various vicissitudes, George of Podiebrad mounted the throne in 1458; and in spite of Papal bull and Hungarian arms maintained his position till his death in 1471. His successor, the Polish prince Ladislas, ultimately obtained also the crown of Hungary; but under him and his son Louis (1517–1526) the nobility made themselves more and

more independent of the king, and the common people were crushed deeper into serfdom. On the death of Louis, in a battle against the Turks at Mohacz, Bohemia passed into the hands of Ferdinand of Austria, who treated the kingdom in the most despotic manner, and in 1547 declared it a hereditary possession. He was followed in succession by his son Maximilian II. and his grandson Rudolph II., who left the country as distracted as they found it. The son of Matthias, the next king, was rejected by the Protestant party, which chose in his stead Frederick V. of the Palatinate; but the victory at the White Mountain in 1620 left Bohemia at the mercy of the emperor, who inflicted a terrible vengeance on his enemies, and in 1627 declared the country a purely Catholic and hereditary kingdom of the empire. Owing to this no fewer than 30,000 families are said to have gone into exile and the population of the country was reduced to 800,000. On the death of Charles VI. Charles Albert of Bavaria laid claim to the crown, which continued to be an object of dispute through the Silesian campaigns and the Seven Years' War, but was successfully defended by Maria Theresa and her son Joseph II. The country was greatly benefited in many ways by the government of that monarch; but he destroyed the independence of the royal towns, and treated the whole land as a mere province of the empire. Its religious condition was considerably improved, however, by an edict of toleration published in 1781. Under the succeeding reigns the circumstances of Bohemia underwent but little alteration, and it was hardly affected by the first French Revolution. In 1848, however, a determined "national" movement agitated the country. The demands of the Liberal party gradually increased, and nothing short of a full share in the constitutional government of their country would suffice. The movement was not confined to Bohemia, but spread through the whole Austrian empire, to the article on which (p. 137 of the present volume) the reader is referred. (See Freher, *Rerum Bohemicarum Antiqui Scriptores*, 1602; Dobner, *Monumenta Historica*, 1764–68; Pelzel, *Geschichte der Bohmen*, 1817; Palacky, *Geschichte von Böhmen*, 1839; Jordan, *Geschichte des böhm. Volks und Landes*, 1845–47.)

The Bohemians or Czechs speak a Slavonic language, which has been subjected to literary culture from about (if not before) the 9th century. A few fragments of a pre-Christian literature have been preserved in a manuscript discovered by Hanka in 1817 in the church-steeple of Königinhof; but the first productions of any extent are due to the activity of the early German Christians, and are composed for the most part in the Latin language. Against this powerful exotic speech the vernacular had a long and dubious struggle, especially in the ecclesiastical domain, and it was still striving against its encroachments when the political circumstances of the nation exposed it to the more dangerous, because more popular and less artificial, rivalry of German. From the court and the capital outward over the nobility and the country there spread a Germanizing energy that at first seemed likely to destroy everything that was distinctively Bohemian; but here and there the national language and customs were fostered and preserved by a few patriotic spirits, among whom the monks of the Slavonic monastery of Sazawa were especially conspicuous. At length the native language obtained the imperial patronage (under Charles IV.) Dalimil wrote his *Rhyming Chronicle of Bohemia* (1314); and translations began to be made from Latin and other languages. Among these were Mandeville's *Travels*; and about the end of the 14th century a complete version of the Scriptures, the manuscript of which is preserved at Nikolsburg in Moravia. Thomas Stitny the domestic moralist, Duba the jurist, and Flaska the didactic poet, deserve to be mentioned as original writers. The next generation saw the attempts at once at religious and at linguistic reform that came to so sad an end in the burning of John Huss and the persecutions that followed. The Bohemian language was, indeed, brought into general use and served the disputants of both sides; but little was consigned to its keeping except the ephemeral productions of ecclesiastical and political strife. A large collection of these works, saved from destruction by the invading Swedes, is still preserved in the library of Stockholm. Of more permanent interest may be mentioned Paul Zidek's *History of the World*, written for George of Podiebrad; the interesting travels of Leo of Rosmital and his companions through various countries of Europe; and those of Kabatnik in Egypt and Asia Minor, and of John of Lobkowitz in Palestine. The 16th century saw a remarkable development of Bohemian prose in various departments of literature. Weleslawin, Paprocky, and Hayck of Liboczun wrote popular histories; Wratislas of Mitrovic and Prefat of Wlkanow gave accounts of their travels; and Nicolas Konec, Dobrensky, and Lomnicky produced didactic works of different kinds. A valuable translation of the Bible was published at Kralitz in Moravia by eight learned Bohemian Brethren at the instigation of John of Zerotin; and various versions of the classics appeared from time to time. A long period of literary decadence followed the battle of the White Mountain in 1620. The best blood of the nation went into exile, and what Bohemian literature was produced appeared for the most part in foreign cities. In 1774 a severe blow was struck at the native language by Maria Theresa's imperial decree which enforced the use of German in the higher and middle schools of the country. Before long, however, the defence of the mother tongue was taken up by Count Kinsky, Hanka of Hankenstein, the historian Pelzel, and the Jesuit Balbin,—by the last mentioned in a *Dissertatio apologetica pro lingua Bohemica*. The language became the object of the scientific investigations of Dobrowsky, and the remains of the early periods were edited by Dobner, Prochazka, and other philologists. A chair of the Bohemian language was founded in the University of Prague, and in 1818 a Bohemian museum was established in connection with a society that devoted itself to the study of national antiquities, and published a valuable journal. Puchmayer (1795–1820) gave an impulse to national poetry, and has been succeeded by Langer, Roko, Wocel, Schneider, Czelakowsky, and Kollar, and a great number of other writers. In the department of science Presl, Sadek, Amerling, Smetana, Petcina, Sloboda, and Opiz have attained distinction. Grammars of the Czech language have been produced by Burian, Hanka, Maly, Sembera, and Tomicek; Sumawsky published a great German-Bohemian dictionary; Spatny, a Bohemian-German and German-Bohemian technological dictionary; and Jungmann a large Bohemian-German lexicon. The names of even the prominent writers in philosophy, theology, and politics are too numerous to be mentioned. (See Schafarik's *Slavisch Alterthumer*, 1842, and *Geschichte der Slav. Sprache*, 1826; Jungmann's *Geschichte der Böhm. Sprache und Literatur*, 1825.)

BOHEMOND, MARC, one of the leaders of the Crusades, born about 1056, was the eldest son of Robert Guiscard, a Norman, who had obtained by conquest the dukedom of Apulia and Calabria. From 1081 to 1085 he served under his father in a war against the Byzantine emperor Alexander Comnenus, whom he twice defeated, though he had to return to Italy without reaping any substantial fruits of his success. In 1085 his father died, leaving Apulia and Calabria to a younger son, while Bohemond obtained only the small principality of Tarentum. A war between the

brothers followed, from which, however, Bohemond was speedily diverted by the Crusades, which opened up a wider field for his ambition. Accompanied by his cousin Tancred, he led an army of 10,000 cavalry and 20,000 infantry, with which he would have besieged Constantinople had he been able to persuade Godfrey of Bouillon to join him. He took a leading part in the battle of Dorylæum (1097), and the other engagements of the campaign in Asia Minor. A year later he besieged and captured Antioch, of which he assumed the principality. In 1101 he was defeated and taken prisoner by the Turks. Released, after a captivity of two years, on the payment of a very heavy ransom, he returned to Europe to collect troops. In 1106 he visited France, and married Constance, a daughter of Philip I. With an army levied in France, in right of his marriage, he renewed war with Alexius, but being unsuccessful in the siege of Durazzo he was obliged to conclude a peace in 1108. He died at Canossa in Apulia in 1111. (See Gibbon's *Decline and Fall*, c. lviii., lx.; and Michaud's *Histoire de Croisades*.)

BOIARDO, Count Matteo Maria, of a noble and illustrious house established at Ferrara, but originally from Reggio, was born at Scandiano, one of the seignoral estates of his family, near Reggio di Modena, about the year 1434, according to Tiraboschi, or 1420 according to Mazzuchelli. At an early age he entered the University of Ferrara, where he acquired a good knowledge of Greek and Latin, and even of the Oriental languages, and was in due time admitted doctor in philosophy and in law. At the court of Ferrara, where he enjoyed the favour of Duke Borso d'Este and his successor Hercules, he was entrusted with several honourable employments, and in particular was named governor of Reggio, an appointment which he held in the year 1478. Three years afterwards he was elected captain of Modena, and reappointed governor of the town and citadel of Reggio, where he died in the year 1494, though in what month is uncertain. Almost all his works, and especially his great poem of the *Orlando Inamorato*, were composed for the amusement of Duke Hercules and his court, though not written within its precincts. His practice, it is said, was to retire to Scandiano or some other of his estates, and there to devote himself to composition; and Castelvetro, Vallisnieri, Mazzuchelli, and Tiraboschi, all unite in stating that he took care to insert in the descriptions of his poem those of the agreeable environs of his chateau, and that the greater part of the names of his heroes, as Mandricardo, Gradasso, Sacripant, Agramant, and others, were merely the names of some of his peasants, which, from their uncouthness, appeared to him proper to be given to Saracen warriors. Be this as it may, the *Orlando Inamorato* deserves to be considered as one of the most important poems in Italian literature, since it forms the first example of the romantic epic worthy to serve as a model, and, as such, undoubtedly produced the *Orlando Furioso*. Gravina and Mazzuchelli have said, and succeeding writers have repeated on their authority, that Boiardo proposed to himself as his model the *Iliad* of Homer; that Paris is besieged like the city of Troy; that Angelica holds the place of Helen; and that, in short, the one poem is a sort of reflex image of the other. In point of fact, however, the subject-matter of the poem is derived from the *Fabulous Chronicle* of the pseudo-Turpin; though, with the exception of the names of Charlemagne, Roland, Oliver, and some other principal warriors, who necessarily figure as important characters in the various scenes, there is little resemblance between the detailed plot of the one and that of the other. The poem, which Boiardo did not live to finish, was printed at Scandiano the year after his death, under the superintendence of his son Count Camillo. The title of the book is without date: but a Latin letter from Antonia Caraffa di Reggio, prefixed to the poem, is dated the kalends of June 1495. A second edition, also without date, but which must have been printed before the year 1500, appeared at Venice; and the poem was twice reprinted there during the first twenty years of the 16th century. These editions are the more curious and valuable, that they contain nothing but the text of the author, which is comprised in three books, divided into cantos, the third book being incomplete. But Niccolo degli Agostini, an indifferent poet, had the courage to continue the work commenced by Boiardo, adding to it three books, which were printed at Venice in 1526–1531, in 4to; and since that time no edition of the *Orlando* has been printed without the continuation of Agostini, wretched as it unquestionably is. Boiardo's poem suffers from the incurable defect of a laboured and heavy style. His story is skilfully constructed, the characters are well drawn and sustained throughout; many of the incidents show a power and fertility of imagination not inferior to that of Ariosto, but the perfect workmanship indispensable for a great work of art is wanting. The poem in its original shape was not popular, and has been completely superseded by the *Rifacimento* of Francesco Berni. See Berni.

The other works of Boiardo are—1. *Il Timone*, a comedy, Scandiano, 1500, 4to; 2. *Sonnetti e Canzoni*, Reggio, 1499, 4to; 3. *Carmen Bucolicon*, Reggio, 1500, 4to; 4. *Cinque Capitoli in terza rima*, Venice, 1523 or 1533; 5. *Apulejo dell' Asino d'Oro*, Venice, 1516, 1518; 6. *Asino d'Oro de Luciano tradotto in volgare*, Venice, 1523, 8vo; 7. *Erodoto Alicarnasseo istorico, tradotto di Greco in Lingua Italiana*, Venice, 1533 and 1538, 8vo; 8. *Rerum Italicarum Scriptores*. (See Panizzi's *Boiardo*, 1830–31.)

BOIELDIEU, François-Adrien, is the chief representative of the national school of comic opera in France, a branch of art in which everything that is most lovable and at the same time most national in the French character has found its full expression. He was born at Rouen in 1775, and received his first musical education from M. Broche, the organist of the cathedral of that city. It is said that, when quite a youth, in order to escape the punishment of a severe master for a slight offence, he went off to Paris on foot, but was discovered and brought back by his parents. He began composing songs and chamber music at a very early age,—his first opera, *La Famille Suisse*, being produced on the stage of Rouen in 1795, where it met with an enthusiastic reception. Not satisfied with his local success he turned his eyes to that loadstar of youthful ambition, Paris. He went to the capital in 1795, full of hope and expectation. The score of his opera was submitted to the leading musicians of the day, such as Cherubini, Méhul, and others, but met with little approbation. Altogether the time was not favourable for the comic muse. The heroic passions roused by the revolutionary events of the preceding years required commensurate efforts of musical art; the grand opera was the order of the day. Boieldieu had to fall back on his talent as a pianoforte-player for a livelihood, and to wait for a chance of higher success in the meantime. This success came at last from a source whence it was little expected, and, perhaps, less desired. Garat, a fashionable singer of the period, admired Boieldieu's touch on the piano, and made him his accompanyist. He also sung in the drawing-rooms of the Directoire the charming songs and ballads with which the young composer supplied him but too willingly. In this manner Boieldieu's reputation gradually extended to wider circles. In 1797 his above-mentioned opera appeared for the first time on a Paris stage, and was well received. Several others followed in rapid succession, of which only the last, *Le Calife de Bagdad* (1799), has escaped oblivion. It tends to show Boieldieu's true artistic vocation, that, after the enormous success of

this work, he felt the want of a thorough musical training, and voluntarily descended from the position of a successful *maestro* to that of a humble pupil. He took lessons from Cherubini, and the influence of that great master is distinctly discernible in the higher artistic finish of Boieldieu's later compositions. In 1802 Boieldieu, for the second time in his life, took to sudden flight, on this occasion in order to escape the domestic troubles caused by his marriage with a celebrated ballet-dancer of the Paris Opera. The frightened husband went to Russia, where he was received with open arms by the Emperor Alexander. During his prolonged stay at St Petersburg he composed a number of operas which it is unnecessary to name. He also set to music the choruses of Racine's *Athalie*, one of his few attempts at the tragic style of dramatic writing. In 1811 he returned to his own country, where the following year witnessed the production of one of his finest works, *Jean de Paris*. The charming coquetry of the queen of Navarre, the chivalrous *verve* of the king, the officious pedantry of the seneschal, and the amorous tenderness of the page—all this rendered in the finest touches that music, and only French music, is capable of, will not soon be forgotten. We pass over a number of other operas of lesser value, partly written in collaboration with other composers, and turn at once to the second and greatest masterpiece of Boieldieu's genius, his *Dame Blanche* (1825). The libretto, written by Scribe, was partly suggested by Walter Scott's *Monastery*, and several original Scotch tunes cleverly introduced by the composer add not a little to the melodious charm and local colour of the work. *La Dame Blanche* marks the highest development of the French school of comic opera. Grétry stood at the head of this school; Cherubini with his *Deux Journées* followed in his wake; Boieldieu, greater than both (in this particular branch of art), reached a perfection which was to some extent sustained by the works of Auber. Boieldieu's pupil, Adam, has in his *Derniers Souvenirs d'un Musicien* left a charming sketch of the genesis of Boieldieu's masterpiece. The chief characteristics of his style are an easy flow of graceful melodies, a refined though occasionally somewhat meagre instrumentation, admirable phrasing, and a most distinct enunciation of the words. The outer events of Boieldieu's career may be summed up in few words. For a long time he occupied the position of professor of composition and pianoforte at the Conservatoire; in 1817 he was made a member of the Institute. The *Dame Blanche* was his last opera but one. Soon after its production he was seized with a violent attack of pulmonary disease. To stop the rapid progress of the illness he travelled in Italy and the South of France, but fell a victim to it on October 8, 1834.

BOII, a Celtic people, who at an early date crossed the Alps and established themselves between the Po and the Apennines to the south of the Insubres and Cenomani. On the defeat of their neighbours the Senones by the Romans they joined the Etruscans against the conquerors, and were involved in the disastrous results of the battle at the Vadimonian Lake in 283 B.C. Equally unsuccessful in the following year, they formed a treaty of peace with the Romans, which they kept for a considerable time, till the encroachments of their conquerors led them to engage in the Great Gallic war of 225 B.C. From that period they continued to indulge their hostility on all occasions, and on the outbreak of the Punic wars gave valuable aid to the Carthaginians from time to time. At length their strength was broken by Scipio Nasica in 191 B.C.; a large proportion of their territory was appropriated and secured by the colonies of Bononia, Parma, and Mutina; and before long the whole race seems to have been constrained to recross the Alps. They betook themselves to that district of country which is still called in consequence Bohemia; but before many centuries they were expelled by other hostile tribes and their separate existence as a people was lost.

BOILEAU-DESPREAUX, NICOLAS, was born at Paris on the 1st November 1636. Crône, not far from the capital, has been frequently stated to be his birthplace, but the matter seems to be pretty nearly settled by the researches of M. Labat (*Recherches historiques sur l'Hôtel de la Préfecture de Police*), who has discovered the very house in the Rue de Jérusalem where the poet was born. He was educated at the College of Beauvais, and was at first destined for the legal profession. From this, however, after a short trial, he recoiled in disgust, complaining bitterly of the amount of chicanery which passed under the name of law and justice. To escape such a course of life he began to study for the church, and actually received a priory of a small annual value, but his wishes soon turned in another direction. He gave up his clerical profession, and, his father having left him a small provision sufficient for his wants, thenceforward devoted himself to letters. Such of his early poems as have been preserved hardly contain the promise of what he ultimately became. The first piece in which his peculiar powers were displayed was a satirical poem, *Adieus of a Poet to the City of Paris*, published in 1660. This was quickly followed by eight others, and the number was at a later period increased to twelve. A twofold interest attaches to the satires. In the first place the author skilfully parodies and attacks writers who at the time were placed in the very first rank, such as Chapelain, Cotin, Quinault, and Scudéri; he openly raised the standard of revolt against the older poets. But in the second place he showed, both by precept and practice, what were the poetical capabilities of the French language. Prose, in the hands of such writers as Descartes and Pascal, had proved itself a flexible and powerful instrument of expression, with a distinct mechanism and form. But except with Malherbe, there had been no attempt to fashion French versification according to rule or method. In Boileau for the first time appeared terseness and vigour of expression, with perfect regularity of verse structure. His fame was quickly established; he received a pension, and was made historiographer along with his friend Racine. In 1664 he composed his prose *Dialogue des heros de roman*, which is a refined satire on the elaborate romances of the time. It may be said to have once for all abolished them. From 1669 onwards appeared the *Epistles*, graver in tone than the satires, maturer in thought, more exquisite and polished in style. In 1674 his two masterpieces, *L'Art Poetique* and *Le Lutrin*, were published. The first, in imitation of the *Ars Poetica* of Horace, lays down the code for all future French verse, and may be said to fill in French literature a parallel place to that held by its prototype in Latin. On our own literature the maxims of Boileau, through the translation revised by Dryden, and through the magnificent imitation of them in Pope's *Art of Criticism*, have exercised no slight influence. Boileau does not merely lay down rules for the language of poetry, but analyses carefully the various kinds of verse composition, and enunciates the principles peculiar to each. Of the four books of the *Art Poetique*, the first and last consist of general precepts, inculcating mainly the great rule of *bon sens*; the second treats of the pastoral, the elegy, the ode, the epigram, and satire; and the third of tragic and epic poetry. Though the rules laid down are of value, their tendency is rather to hamper and render too mechanical the efforts of poetry. Boileau himself, though a great critic in verse, cannot be considered a great poet. The *Lutrin*, a mock heroic poem, of which four cantos appeared in 1674,

is by French critics considered the best of Boileau's works. It has furnished the model for the *Rape of the Lock*, but the English poem is superior in richness of imagination and subtilty of invention. The fifth and sixth cantos, afterwards added by Boileau, rather detract from the beauty of the poem; the last canto in particular is quite unworthy of his genius. In the same year which saw the *Art Poetique* and the *Lutrin* was published his translation of Longinus *On the Sublime*, to which were afterwards added certain critical reflections. His later publications were chiefly occasional poems, in which his better powers did not shine. He died 13th March 1711. Boileau was extremely delicate in youth, and his constitution seems never to have been very strong. He was a man of warm and kindly feelings, honest, outspoken, and benevolent. Many anecdotes are told of his frankness of speech at court, and of his generous actions. He holds a well-defined place in French literature, as the first who reduced its versification to rule and who taught the value of workmanship for its own sake. His influence on English literature, through Pope and his contemporaries, was not less strong, though less durable. Editions of Boileau's works are very numerous. Perhaps the best is that published by Garnier in 1860, *Œuvres complètes*, with copious notes, an essay by Sainte-Beuve, and *Bolœana*.

BOILER. See Steam Engine.

BOIS-LE-DUC, 's Hertogenbosch, or 's Bosch, a city of Holland, capital of the province of North Brabant, 28 miles S.S.E. of Utrecht. It stands at the confluence of the Dommel and the Aa, and is strongly fortified, being defended by a citadel and two forts. The city is handsome and well built, and is intersected by several canals. It contains seven churches, among which is that of St John, founded in the beginning of the 14th century, and one of the finest ecclesiastical edifices in Holland. It has also a handsome town-hall, surmounted by a tower containing a fine set of chimes, a court-house, Government buildings (formerly a Jesuit monastery), an episcopal palace, an orphan asylum, a grammar school (once attended by Erasmus), a prison, two hospitals, an arsenal, and barracks. The trade of Bois-le-Duc is very considerable; it has several distilleries, breweries, and glass-works, and manufactures linen, needles, cutlery, &c. It is the seat of a vicar-general, and has tribunals of primary instance and commerce. Originally a hunting-lodge of the Brabant dukes, 's Hertogenbosch, or "Duke's Wood," gradually increased, and in 1184 was raised to the rank of a town and surrounded with walls. In 1453 it was greatly enlarged. Successive attempts made by the Netherlands in 1585, 1594, 1601, and 1603 to get possession of the town were futile; but at length, in 1629, it was captured after a five months' siege. In 1794 it was taken by the French, and in 1814 by the Prussians. Population in 1869, 24,395.

BOISSARD, Jean Jacques, a classical antiquary and Latin poet, was born at Besançon in 1528. He studied at Louvain; but, disgusted by the severity of his master, he secretly left that seminary, and after traversing a great part of Germany reached Italy, where he remained several years, and was often reduced to great straits. His residence in Italy developed in his mind a taste for antiquities, and he soon formed a collection of the most curious monuments of Rome and its vicinity. He then visited the islands of the Archipelago, with the intention of travelling through Greece, but a severe illness obliged him to return to Rome. Here he resumed his favourite pursuits with great ardour, and having completed his collection, returned to his native country; but not being permitted to profess publicly the Protestant religion, which he had embraced some time before, he withdrew to Metz, where he died, October 30, 1602. His works are—

1. *Poemata, Epigrammatum libri tres, Elegiæ libri tres, Epistolarum libri tres*, Basel, 1574; 2. *Emblemata*, Metz, 1584; 3. *Icones Virorum Illustrium*, 1597, *sqq.*; 4. *Vitæ et Icones Sultanorum Turcicorum*, &c., Frankfort, 1596; 5. *Theatrum Vitæ Humanæ*, Metz, 1596; 6. *Romanæ Urbis Topographiæ et Antiquitatum, quibus succincte et breviter describuntur omnia quæ tum publice quum privatim videntur animadversione digna, partes VI.*, Frankfort, 1597–1602, folio, six volumes in three, with plates, and now very rare; 7. *Icones et Vitæ Virorum Illustrium*, Frankfort, 1592 to 1599; 8. *Parnassus Biceps*, Frankfort, 1601; 9. *De Divinatione et Magicis Præstigiis*, Oppenheim and Hanau, rare and curious; 10. *Habitus Variarum Gentium*, Metz, 1581, ornamented with seventy illuminated figures.

BOISSONADE, Jean François, French classical scholar, was born at Paris, 12th August 1774. In 1792 he entered the public service during the administration of General Dumouriez. Driven from it in 1795, he was restored by Lucien Bonaparte, during whose time of office he served as secretary to the prefecture of the Upper Marne. He then definitively resigned public employment and devoted himself to the study of Greek, for which he had always a strong inclination. In 1809 he was named professor of Greek at the faculty of letters at Paris, though he did not assume the title till the death of Larcher, who held the chair, in 1812. In 1828 he succeeded Gail in the chair of Greek at the Collége de France. He also held the offices of librarian of the Bibliothèque du Roi, and perpetual secretary of the Academy of Inscriptions. He died 12th September 1857. Boissonade's works consist mainly of editions of several less known classical writers, such as Philostratus, Marinus, Eunapius, Aristænetus. Perhaps his most widely known editions are those of Babrius (1844), and of Tzetzes (1851). The *Anecdota Græca*, 5 vols. (1829–33), and *Anecdota Nova* (1844) contain many interesting and comparatively unknown writings. Boissonade was a contributor to the *Journal des Débats* and other critical journals, and a selection of his papers has been published by M. Colincamp, *Critique littéraire sous le premier Empire*, 2 vols., 1863.

END OF VOLUME THIRD.
